**Rationale:** In developmental dysplasia of the hip, the head of the femur is seated improperly in the acetabulum or hip socket of the pelvis. Ortolani’s maneuver is a test to assess for hip instability and can be done only before 4 weeks of age. The examiner abducts the thigh and applies gentle pressure forward over the greater trochanter. A “clicking” sensation indicates a dislocated femoral head moving into the acetabulum. Babinski’s sign is abnormal in anyone older than 2 years of age and indicates central nervous system abnormality. The Moro reflex is normally present at birth but is absent by 6 months; if still present at 6 months, there is an indication of neurological abnormality. The palmar-plantar grasp is present at birth and lessens within 8 months.

**Test-Taking Strategy:** Options 1 and 2 can be eliminated first because they are comparable or alike and are both tests of neurological function. To select from the remaining options, remember that Ortolani’s maneuver is an assessment technique for hip dysplasia that must be done before 4 weeks of age. This will direct you to the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Pediatrics: Musculoskeletal  
**Health Problem:** Pediatric-Specific: Developmental Dysplasia of Hip  
**Priority Concepts:** Clinical Judgment; Mobility  

400. **Answer:** 1

**Rationale:** In developmental dysplasia of the hip, the head of the femur is seated improperly in the acetabulum or hip socket of the pelvis. Asymmetrical and restricted abduction of the affected hip, when the child is placed supine with the knees and hips flexed, would be an assessment finding in developmental dysplasia of the hip in infants beyond the newborn period. Other findings include an apparent short femur on the affected side, asymmetry of the gluteal skinfolds, and limited range of motion in the affected extremity.

**Test-Taking Strategy:** Note the subject, assessment findings in developmental dysplasia of the hip. Also, note the age of the infant and focus on the infant’s diagnosis. Visualizing each of the assessment findings described in the options will
401. **Answer: 3**

**Rationale:** Clubfoot is a complex deformity of the ankle and foot that includes forefoot adduction, midfoot supination, hindfoot varus, and ankle equinus; the defect may be unilateral or bilateral. Treatment for clubfoot is started as soon as possible after birth. Serial manipulation and casting are performed at least weekly. If sufficient correction is not achieved in 3 to 6 months, surgery usually is indicated. Because clubfoot can recur, all children with clubfoot require long-term interval follow-up until they reach skeletal maturity to ensure an optimal outcome. 

**Test-Taking Strategy:** Note the **strategic words**, need for further teaching. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. This will assist you in eliminating options 1 and 2. Recalling that serial manipulations and casting are required weekly will assist in directing you to the correct option.

**Level of Cognitive Ability:** Evaluating
**Client Needs:** Physiological Integrity
**Integrated Process:** Teaching and Learning
**Content Area:** Pediatrics: Musculoskeletal
**Health Problem:** Pediatric-Specific: Clubfoot
**Priority Concepts:** Client Education; Mobility

402. **Answer: 2, 5, 6**

**Rationale:** While the cast is drying, the palms of the hands are used to lift the cast. If the fingertips are used, indentations in the cast could occur and cause constant pressure on the underlying skin. Small toys and sharp objects are kept away from the cast, and no objects (including padded objects) are placed inside the cast because of the risk of altered skin integrity. The extremity is elevated to prevent swelling, and the PHCP is notified immediately if any signs of neurovascular impairment develop. A heating pad is not applied to the cast or fingers. Cold fingers could indicate neurovascular impairment, and the PHCP should be notified. 

**Test-Taking Strategy:** Use of the ABCs—airway, breathing, and circulation—and safety principles related to care of a child with a cast will assist in answering this question.

**Level of Cognitive Ability:** Applying
**Client Needs:** Physiological Integrity
**Integrated Process:** Teaching and Learning

CHAPTER 40

Immune Problems and Infectious Diseases

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts

Infection; Safety

I. Immune Disorders: For information on the functions of the immune system, the immune response, immunodeficiency, and other immune disorders, hypersensitivity and allergies, and skin testing, see Chapter 62.

II. Human Immunodeficiency Virus Infection and Acquired Immunodeficiency Syndrome

A. Description

1. Acquired immunodeficiency syndrome (AIDS) is a disorder caused by human immunodeficiency virus (HIV) and characterized by generalized dysfunction of the immune system (Fig. 40-1).
2. The diagnosis of AIDS is associated with certain illnesses or conditions.
3. HIV infects CD4+ T cells; a gradual decrease in CD4+ T-cell count occurs, and this results in a progressive immunodeficiency; the risk for opportunistic infections is present (Box 40-1).
4. HIV is transmitted through blood, semen, vaginal secretions, and breast milk; the incubation period is months to years.
5. Horizontal transmission occurs through intimate sexual contact or parenteral exposure to blood or body fluids that contain the virus.
6. Vertical (perinatal) transmission occurs from an HIV-infected pregnant woman to her fetus (see Chapter 22).
7. The most common opportunistic infection that occurs in children infected with HIV is *Pneumocystis jiroveci* pneumonia; *P. jiroveci* pneumonia most frequently occurs between the ages of 3 and 6 months.
An infant or child infected with HIV is at risk for developing a life-threatening opportunistic infection. Monitor the infant or child closely for signs of infection and report these signs immediately if they occur.

B. Assessment (see Box 40-1 and Box 40-2)

C. Diagnostic tests: Before testing, counseling should be provided to parents; issues that should be addressed include the causes of HIV, reasons for testing, implications of positive test results, confidentiality issues, and beneficial effects of early intervention (Table 40-1).

III. Care of the Child with HIV Infection or AIDS

A. An interprofessional health care approach is taken; primary goals are to decelerate the replication of the virus, prevent opportunistic infections, provide nutritional support, treat symptoms, and treat opportunistic infections.

B. Prophylaxis (P. jiroveci pneumonia and other opportunistic infections)

1. Provide prophylaxis as prescribed against P. jiroveci pneumonia and other opportunistic infections, particularly during the first year of life of an infant born to an HIV-infected mother.
2. After 1 year of age, the need for prophylaxis is determined on the basis of the presence and severity of immunosuppression or a history of P. jiroveci pneumonia.
3. Continuing prophylaxis is based on the child’s HIV status, history of opportunistic infections, and CD4+ counts.

C. Antiretroviral medications (refer to Chapter 63)

Before administering an antiretroviral medication, ensure that the medication is safe for pediatric administration. Also check the contraindications for use and the adverse effects.

1. The goal of antiretroviral medications is to suppress viral replication to slow the decline in the number of CD4+ cells, preserve immune function, reduce the incidence and severity of opportunistic infections, and delay disease progression.
2. The medications affect different stages of the HIV life cycle to prevent reproduction of new virus particles.
3. Combination therapy may be prescribed and includes
the use of more than 1 antiretroviral medication.

D. Immunizations (refer to Chapter 18 for specific information on childhood immunizations)

Immunization against childhood diseases is recommended for all children exposed to and infected with HIV.

1. If a child has symptomatic HIV infection or has severe immunosuppression, guidelines are as follows:
   a. Only the inactivated influenza vaccine that is given intramuscularly should be used (influenza vaccine should be given yearly).
   b. Measles vaccine should not be given; immunoglobulin may be prescribed after measles exposure.
   c. Only the inactivated polio vaccine that is given intramuscularly should be used.
   d. Rotavirus vaccine should not be given.
   e. Varicella-zoster virus vaccine should not be given; varicella-zoster immunoglobulin may be prescribed after chickenpox exposure.
   f. Tetanus immunoglobulin may be prescribed for tetanus-prone wounds.

E. Caregiver instructions

1. Wash hands frequently.
2. Assess the child for fever, malaise, fatigue, weight loss, vomiting, diarrhea, altered activity level, and oral lesions; notify the pediatrician if any of these occur.
3. Assess the child for signs and symptoms of opportunistic infections, such as pneumonia.
4. Administer antiretroviral medications and other medications to the child as prescribed.
5. The child needs to be restricted from having contact with persons who have infections or other contagious or potentially contagious illnesses.
6. Keep the child’s immunizations up to date.
7. Keep the child home when sick.
8. Avoid direct unprotected contact with the child’s body fluids.
9. Monitor the child’s weight.
10. Provide a high-calorie and high-protein diet to the child.
11. Administer appetite stimulants to the child as prescribed and as needed.
12. Do not share eating utensils with the child.
13. Wash all eating utensils in the dishwasher.
14. Cover any of the child’s unused food and formula and refrigerate (discard unused refrigerated formula and food after 24 hours).
15. Do not allow the child to eat fresh fruits or vegetables or raw meat or fish (neutropenic diet if immunosuppressed).
16. Wear gloves when caring for the child, especially when in contact with body fluids and changing diapers.
17. Change the child’s diapers frequently, away from food areas.
18. Fold the child’s soiled disposable diapers inward, close with the tabs, and dispose in a tightly covered plastic-lined container.
19. Dispose of trash daily.
20. Clean up any of the child’s body fluid spills with a bleach solution (10:1 ratio of water to bleach).

F. Education for an adolescent infected with HIV

1. Educate about high-risk behaviors and the importance of avoiding high-risk behaviors.
2. Identify the methods of transmission of HIV.
3. Emphasize the importance of abstinence from sexual contact, such as intercourse.
4. Emphasize the importance of using safe condoms if intercourse is planned.
5. Identify the resources available for support and other issues.

IV. Rubeola (Measles)
A. Description
1. Agent: Paramyxovirus
2. Incubation period: 10 to 20 days
3. Communicable period: From 4 days before to 5 days after rash appears, mainly during the prodromal stage (pertaining to early symptoms that may mark the onset of disease)
4. Source: Respiratory tract secretions, blood, or urine of infected person
5. Transmission: Airborne particles or direct contact with infectious droplets; transplacental

B. Assessment (Fig. 40-2)
1. Fever
2. Malaise
3. The 3 “Cs”—coryza, cough, conjunctivitis

4. Rash appears as red, erythematous maculopapular eruption starting on the face and spreading downward to the feet; blanches easily with pressure and gradually turns a brownish color (lasts 6 to 7 days); may have desquamation.

5. Koplik’s spots: Small red spots with a bluish white center and a red base; located on the buccal mucosa and last 3 days

C. Interventions

1. Use airborne, droplet, and contact precautions if the child is hospitalized.
2. Restrict child to quiet activities and bed rest.
3. Use a cool mist vaporizer for cough and coryza.
4. Dim lights if photophobia is present.
5. Administer antipyretics for fever.
6. Administer vitamin A supplementation as prescribed.

V. Roseola (Exanthema Subitum)

A. Description

1. Agent: Human herpesvirus type 6
2. Incubation period: 5 to 15 days
3. Communicable period: Unknown, but thought to extend from the febrile stage to the time the rash first appears
4. Source: Unknown
5. Transmission: Unknown

B. Assessment (Fig. 40-3)

1. Sudden high (> 38.8° C [> 102° F]) fever of 3 to 5 days’ duration in a child who appears well, followed by a rash (rose-pink macules that blanch with pressure); febrile seizures may occur
2. Rash appears several hours to 2 days after the fever subsides and lasts 1 to 2 days.

C. Interventions: Supportive

VI. Rubella (German Measles)

A. Description

1. Agent: Rubella virus
2. Incubation period: 14 to 21 days
3. Communicable period: From 7 days before to about 5 days after rash appears
4. Source: Nasopharyngeal secretions; virus is also present in blood, stool, and urine
5. Transmission
   a. Airborne or direct contact with infectious droplets
   b. Indirectly via articles freshly contaminated with nasopharyngeal secretions, feces, or urine
   c. Transplacental

B. Assessment (Fig. 40-4)
   1. Low-grade fever
   2. Malaise
   3. Pinkish red maculopapular rash that begins on the face and spreads to the entire body within 1 to 3 days
   4. Petechiae (red, pinpoint spots) may occur on the soft palate.

C. Interventions
   1. Use airborne, droplet, and contact precautions if the child is hospitalized; provide supportive treatment.
   2. Isolate the infected child from pregnant women.

VII. Mumps
A. Description
   1. Agent: Paramyxovirus
   2. Incubation period: 14 to 21 days
   3. Communicable period: Immediately before and after parotid gland swelling begins
   4. Source: Saliva of infected person and possibly urine
   5. Transmission: Direct contact or droplet spread from an infected person

B. Assessment
   1. Fever
   2. Headache and malaise
   3. Anorexia
   4. Jaw or ear pain aggravated by chewing, followed by parotid glandular swelling
   5. Orchitis or oophoritis may occur.
   6. Deafness may occur.
   7. Aseptic meningitis may occur.

C. Interventions
   1. Institute airborne, droplet, and contact precautions.
2. Provide bed rest until the parotid gland swelling subsides.
3. Avoid foods that require chewing.
4. Apply hot or cold compresses as prescribed to the neck.
5. Apply warmth and local support with snug-fitting underpants to relieve orchitis.
6. Monitor for signs of aseptic meningitis (see Chapters 38 and 58 for information on meningitis).

VIII. Chickenpox (Varicella)

A. Description
1. Agent: Varicella-zoster (VCZ) virus
2. Incubation period: 13 to 17 days
3. Communicable period: From 1 to 2 days before the onset of the rash to 6 days after the first crop of vesicles, when crusts have formed
4. Source: Respiratory tract secretions of infected person; skin lesions
5. Transmission: Direct contact, airborne, droplet spread, and contaminated objects

B. Assessment (Fig. 40-5)
1. Slight fever, malaise, and anorexia are followed by a macular rash that first appears on the trunk and scalp and moves to the face and extremities.
2. Lesions become pustules, begin to dry, and develop a crust.
3. Lesions may appear on the mucous membranes of the mouth, the genital area, and the rectal area.

C. Interventions
1. In the hospital, ensure strict isolation (contact and, droplet, precautions).
2. At home, isolate the infected child until the vesicles have dried.
3. An antiviral agent may be used to treat varicella infections in susceptible immunocompromised persons to decrease the number of lesions; shorten the duration of fever; and decrease itching, lethargy, and anorexia.
4. The use of varicella zoster (VCZ) immune globulin or intravenous immune globulin (IVIG) is recommended for children who are immunocompromised, who have no previous history of varicella, and who are likely to contract the disease and have complications as a result.
5. Provide supportive care.

*Isolate high-risk children, such as children who have immunosuppressive disorders, from a child with a communicable disease.*

IX. Pertussis (Whooping Cough)

A. Description

1. Agent: Bordetella pertussis
2. Incubation period: 5 to 21 days (usually 10 days)
3. Communicable period: Greatest during the catarrhal stage (when discharge from respiratory secretions occurs)
4. Source: Discharge from the respiratory tract of the infected person
5. Transmission: Direct contact or droplet spread from infected person; indirect contact with freshly contaminated articles

B. Assessment

1. Symptoms of respiratory infection followed by increased severity of cough, with a loud whooping inspiration
2. May experience cyanosis, respiratory distress, and tongue protrusion
3. Listlessness, irritability, anorexia

C. Interventions

1. Isolate child during the catarrhal stage; if the child is hospitalized, institute airborne, droplet, and contact precautions.
2. Administer antimicrobial therapy as prescribed.
3. Reduce environmental factors that cause coughing spasms, such as dust, smoke, and sudden changes in temperature.
4. Ensure adequate hydration and nutrition.
5. Provide suction and humidified oxygen if needed.
6. Monitor cardiopulmonary status (via monitor as prescribed) and pulse oximetry.
7. Infants do not receive maternal immunity to pertussis; the tetanus–diphtheria–acellular pertussis (Tdap) vaccine should be administered to women in the postpartum period and those in close contact with
the infant to prevent the spread of pertussis to infants.

X. Diphtheria

A. Description

1. Agent: Corynebacterium diphtheriae
2. Incubation period: 2 to 5 days
3. Communicable period: Variable, until virulent bacilli are no longer present (3 negative cultures of discharge from the nose and nasopharynx, skin, and other lesions); usually 2 weeks, but can be 4 weeks
4. Source: Discharge from the mucous membrane of the nose and nasopharynx, skin, and other lesions of the infected person
5. Transmission: Direct contact with infected person, carrier, or contaminated articles

B. Assessment

1. Low-grade fever, malaise, sore throat
2. Foul-smelling, mucopurulent nasal discharge
3. Dense pseudomembrane formation in the throat that may interfere with eating, drinking, and breathing
4. Lymphadenitis, neck edema, “bull neck”

C. Interventions

1. Ensure strict isolation for the hospitalized child.
2. Administer diphtheria antitoxin as prescribed (after a skin or conjunctival test to rule out sensitivity to horse serum).
3. Provide bed rest.
4. Administer antibiotics as prescribed.
5. Provide suction and humidified oxygen as needed.
6. Provide tracheostomy care if a tracheotomy is necessary.

XI. Poliomyelitis

A. Description

1. Agent: Enteroviruses
2. Incubation period: 7 to 14 days
3. Communicable period: Unknown; the virus is present in the throat and feces shortly after infection and persists for about 1 week in the throat and 4 to 6 weeks in the feces
4. Source: Oropharyngeal secretions and feces of the infected person
5. Transmission: Direct contact with infected person; fecal-oral and oropharyngeal routes

B. Assessment
1. Fever, malaise, anorexia, nausea, headache, sore throat
2. Abdominal pain followed by soreness and stiffness of the trunk, neck, and limbs that may progress to central nervous system paralysis

C. Interventions
1. Enteric and contact precautions
2. Supportive treatment
3. Bed rest
4. Monitoring for respiratory paralysis
5. Physical therapy

XII. Scarlet Fever
A. Description
1. Agent: Group A β-hemolytic streptococci
2. Incubation period: 1 to 7 days
3. Communicable period: About 10 days during the incubation period and clinical illness; during the first 2 weeks of the carrier stage, although may persist for months
4. Source: Nasopharyngeal secretions of infected person and carriers

5. Transmission: Direct contact with infected person or droplet spread; indirectly by contact with contaminated articles, ingestion of contaminated milk, or other foods

B. Assessment (Fig. 40-6)
1. Abrupt high fever, flushed cheeks, vomiting, headache, enlarged lymph nodes in the neck, malaise, abdominal pain
2. A red, fine sandpaper–like rash develops in the axilla, groin, and neck that spreads to cover the entire body except the face.
3. Rash blanches with pressure; pink or red lines of petechiae are noted in areas of deep creases and folds of the joints (Pastia’s sign).
4. Desquamation, sheet-like sloughing of the skin on palms and soles, appears by weeks 1 to 3.
5. The tongue is initially coated with a white, furry covering with red projecting papillae (white strawberry tongue); by the third to fifth day, the white coat sloughs off, leaving a red swollen tongue
6. Tonsils are reddened, edematous, and covered with exudate.
7. Pharynx is edematous and beefy red.

C. Interventions

1. Institute contact and airborne (droplet) precautions until 24 hours after initiation of antibiotics.
2. Provide supportive therapy.
3. Provide bed rest.
4. Encourage fluid intake.

XIII. Erythema Infectiosum (Fifth Disease)

A. Description
1. Agent: Human parvovirus B19
2. Incubation period: 4 to 14 days; may be 20 days
3. Communicable period: Uncertain but before the onset of symptoms in most children
4. Source: Infected person
5. Transmission: Unknown; possibly respiratory secretions and blood

B. Assessment
1. Before rash: Asymptomatic or mild fever, malaise, headache, runny nose
2. Stages of rash
   a. Erythema of the face (slapped-cheek appearance) develops and disappears by 1 to 4 days (Fig. 40-7).
   b. About 1 day after the rash appears on the face, maculopapular red spots appear, symmetrically distributed on the extremities; the rash progresses from proximal to distal surfaces and may last a week or more.
   c. The rash subsides but may reappear if the skin becomes irritated by the sun, heat, cold, exercise, or friction.

C. Interventions
1. Child is not usually hospitalized.
2. Pregnant women should avoid the infected individual.
3. Provide supportive care.
4. Administer antipyretics, analgesics, and anti-inflammatory medications as prescribed.
XIV. Infectious Mononucleosis
A. Description
1. Agent: Epstein-Barr virus
2. Incubation period: 4 to 6 weeks
3. Communicable period: Unknown
4. Source: Oral secretions
5. Transmission: Direct intimate contact

B. Assessment
1. Fever, malaise, headache, fatigue, nausea, abdominal pain, sore throat, enlarged red tonsils
2. Lymphadenopathy and hepatosplenomegaly
3. Discrete macular rash most prominent over the trunk may occur.

C. Interventions
1. Provide supportive care.
2. Monitor for signs of splenic rupture.

Teach the parents of a child with mononucleosis to monitor for signs of splenic rupture, which include abdominal pain, left upper quadrant pain, and left shoulder pain.

XV. Rocky Mountain Spotted Fever
A. Description
1. Agent: Rickettsia rickettsii
2. Incubation period: 2 to 14 days
3. Source: Tick from a mammal, most often from wild rodents and dogs
4. Transmission: Bite of infected tick

B. Assessment
1. Fever, malaise, anorexia, vomiting, headache, myalgia
2. Maculopapular or petechial rash primarily on the extremities (ankles and wrists), but may spread to other areas, characteristically on the palms and soles

C. Interventions
1. Provide vigorous supportive care.
2. Administer antibiotics as prescribed.
3. Teach the child and parents about protection from tick bites (Box 40-3).

XVI. Community-Associated Methicillin-Resistant Staphylococcus aureus (CA-MRSA)
A. Description (also see Chapter 13)
1. *Staphylococcus aureus* is a bacterium that is normally located on the skin or in the nose of healthy people; when present without symptoms, it is called colonization, and when symptoms are present, it is called an infection.

2. MRSA is a strain of *S. aureus* that is resistant to methicillin and most often occurs in people who were hospitalized or treated at a health care facility (hospital-acquired MRSA).

3. CA-MRSA is an MRSA infection that occurs in a healthy person who has not been hospitalized or had a medical procedure done within the past year.

4. Persons at risk for CA-MRSA include athletes, prisoners, day care attendees, military recruits, persons who abuse intravenous drugs, persons living in crowded settings, persons with poor hygiene practices, persons who use contaminated items, persons who get tattoos, and persons with a compromised immune system.

5. CA-MRSA is spread through person-to-person contact, through contact with contaminated items, or through infection of a preexisting cut or wound that is not protected by a dressing.

6. The bacteria can enter the bloodstream through the cut or wound and cause sepsis, cellulitis, endocarditis, osteomyelitis, septic arthritis, toxic shock syndrome, pneumonia, organ failure, and death.

B. Prevention measures

1. Frequent hand washing and strict aseptic technique in health care facilities
2. Hand washing and practicing good personal hygiene
3. Avoiding sharing of personal items
4. Regular cleaning of shared equipment such as athletic equipment, whirlpools, or saunas
5. Cleaning a cut or wound thoroughly
6. Ensure tattoo or body piercing facilities adhere to strict guidelines regarding preventing infection

C. Assessment

1. Appearance of a skin infection: Red, swollen area; warmth around the area; drainage of pus; pain at the site; fever
2. Symptoms of a more serious infection: Chest pain, cough, fatigue, chills, fever, malaise, headache, muscle aches, shortness of breath, rash

D. Interventions

1. Assess skin lesions.
2. Prepare to drain an infected skin site and culture the
wound and wound drainage.
3. Prepare to obtain blood cultures, sputum cultures, and urine cultures.
4. Prepare to administer antibiotics as prescribed.
5. Educate the child and family about the causes and modes of transmission, signs and symptoms, and importance of treatment measures prescribed.

XVII. Influenza

A. Description
1. Various strains of influenza can occur.
2. It is a viral infection that affects the respiratory system and is highly contagious.
3. Children, pregnant women, persons with pre-existing health conditions, and persons with a compromised immune system are at high risk for developing complications.
4. It is caused by contact with an infected person or by touching something such as a toy or tissue that the infected person has touched.

B. Prevention
1. Flu vaccine
2. Wash the child’s hands frequently and teach hand-washing techniques.
3. Avoid children who are ill.
4. Keep the child home from school or away from others until the child has been fever-free (without the use of antipyretics) for at least 24 hours.
5. For additional information, refer to Centers for Disease Control and Prevention (CDC) Web site: http://www.cdc.gov/vaccines/schedules/index.html.

The signs and symptoms of flu usually last a week. If they last longer, the presence of complications should be suspected.

C. Assessment
1. Fever that occurs suddenly and is high
2. Headache, body aches, fatigue, chills, cough, congestion, sore throat, loss of appetite, vomiting, diarrhea

D. Interventions
1. Antiviral medications if prescribed, fluids, rest, pain relievers such as acetaminophen or ibuprofen
2. Family and child teaching about prevention measures
FIG. 40-1 Components of the immune system. Ig, Immunoglobulin.

Box 40-1

Common Acquired Immunodeficiency Syndrome (AIDS)—Defining Conditions in Children

- Candidal esophagitis
- Cryptosporidiosis
- Cytomegalovirus disease
- Herpes simplex disease
- Human immunodeficiency virus encephalopathy
- Lymphoid interstitial pneumonitis
- Mycobacterium avium-intracellulare infection
- Pneumocystis jiroveci pneumonia
- Pulmonary candidiasis
- Recurrent bacterial infections
- Wasting syndrome

Data from Perry S, Hockenberry M, Lowdermilk D, Wilson D: Maternal-child nursing
Box 40-2
Common Assessment Findings in Children with Human Immunodeficiency Virus (HIV) Infection

- Chronic cough
- Chronic or recurrent diarrhea
- Developmental delay or regression of developmental milestones
- Failure to thrive
- Hepatosplenomegaly
- Lymphadenopathy
- Malaise and fatigue
- Night sweats
- Oral candidiasis
- Parotitis
- Weight loss

Table 40-1
Diagnostic Tests for Human Immunodeficiency Virus (HIV)

<table>
<thead>
<tr>

FIG. 40-5 Chickenpox (varicella). (From Habif, 2004.)
First day of rash
- Flushed cheeks
- White strawberry tongue (see below)
- Increased density on neck
- Transverse lines (Pastia’s sign)
- Increased density in groin

Third day of rash
- Circumoral pallor
- Red strawberry tongue (see below)
- Increased density in axilla
- Positive blanching test

First day
- White strawberry tongue

Third day
- Red strawberry tongue
Box 40-3

Measures to Protect Children from Tick Bites

- Wearing long-sleeved shirts, long pants tucked into long socks (socks should be pulled up over the pant legs), and a hat when walking in tick-infested areas
- Wearing light-colored clothing to make ticks more visible if they get onto the child
- Checking children for the presence of ticks after being in high-risk or tick-infested areas
- Following paths rather than walking in tall grass and shrub areas, because these are the places where most ticks are found
• Applying insect repellents containing diethyltoluamide (DEET) and permethrin before possible exposure to areas where ticks are found (use with caution in infants and small children)
• Keeping yards at home trimmed and free of accumulating leaves and other brush
• Applying tick repellent to dogs
• Saving the tick for later identification if it is removed from the child’s body
• To remove the tick, grasp the tick at the point of closest contact to the skin with tweezers and pull straight up with steady, even pressure; remove any remaining parts with a sterile needle; if using bare hands, use a tissue during removal; wash hands with soap and water.

Practice Questions

403. An infant of a mother infected with human immunodeficiency virus (HIV) is seen in the clinic each month and is being monitored for symptoms indicative of HIV infection. With knowledge of the most common opportunistic infection of children infected with HIV, the nurse assesses the infant for which sign?
1. Cough
2. Liver failure
3. Watery stool
4. Nuchal rigidity

404. The nurse provides home care instructions to the parent of a child with acquired immunodeficiency syndrome (AIDS). Which statement by the parent indicates the need for further teaching?
1. “I will wash my hands frequently.”
2. “I will keep my child’s immunizations up to date.”
3. “I will avoid direct unprotected contact with my child’s body fluids.”
4. “I can send my child to day care if he has a fever, as long as it is a low-grade fever.”

405. The clinic nurse is instructing the parent of a child with human immunodeficiency virus (HIV) infection regarding immunizations. The nurse should provide which instruction to the parent?
1. The hepatitis B vaccine will not be given to the child.
2. The inactivated influenza vaccine will be given yearly.
3. The varicella vaccine will be given before 6 months of age.
4. A Western blot test needs to be performed and the results evaluated before immunizations.

406. A pediatrician prescribes laboratory studies for an infant of a woman positive for human immunodeficiency virus (HIV). The nurse anticipates that which laboratory study will be prescribed for the infant?
1. Chest x-ray
2. Western blot
3. CD4+ cell count
4. p24 antigen assay

407. The mother with human immunodeficiency virus (HIV) infection brings her 10-month-old infant to the clinic for a routine checkup. The pediatrician has documented that the infant is asymptomatic for HIV infection. After the checkup, the mother tells the nurse that she is so pleased that the infant will not get HIV infection. The nurse should make which most appropriate response to the mother?

1. “I am so pleased also that everything has turned out fine.”
2. “Because symptoms have not developed, it is unlikely that your infant will develop HIV infection.”
3. “Everything looks great, but be sure to return with your infant next month for the scheduled visit.”
4. “Most children infected with HIV develop symptoms within the first 9 months of life, and some become symptomatic sometime before they are 3 years old.”

408. A 6-year-old child with human immunodeficiency virus (HIV) infection has been admitted to the hospital for pain management. The child asks the nurse if the pain will ever go away. The nurse should make which best response to the child?

1. “The pain will go away if you lie still and let the medicine work.”
2. “Try not to think about it. The more you think it hurts, the more it will hurt.”
3. “I know it must hurt, but if you tell me when it does, I will try to make it hurt a little less.”
4. “Every time it hurts, press on the call button and I will give you something to make the pain go all away.”

409. The home care nurse provides instructions regarding basic infection control to the parent of an infant with human immunodeficiency virus (HIV) infection. Which statement, if made by the parent, indicates the need for further instruction?

1. “I will clean up any spills from the diaper with diluted alcohol.”
2. “I will wash baby bottles, nipples, and pacifiers in the dishwasher.”
3. “I will be sure to prepare foods that are high in calories and high in protein.”
4. “I will be sure to wash my hands carefully before and after caring for my infant.”

410. Which home care instructions should the nurse provide to the parent of a child with acquired immunodeficiency syndrome (AIDS)? Select all that apply.

☐ 1. Monitor the child’s weight.
☐ 2. Frequent hand washing is important.
☐ 3. The child should avoid exposure to other illnesses.
☐ 4. The child’s immunization schedule will need revision.
☐ 5. Clean up body fluid spills with bleach solution (10:1 ratio of
6. Fever, malaise, fatigue, weight loss, vomiting, and diarrhea are expected to occur and do not require special intervention.

411. The nurse provides home care instructions to the parents of a child hospitalized with pertussis who is in the convalescent stage and is being prepared for discharge. Which statement by a parent indicates a need for further instruction?

1. “We need to encourage our child to drink fluids.”
2. “Coughing spells may be triggered by dust or smoke.”
3. “Vomiting may occur when our child has coughing episodes.”
4. “We need to maintain droplet precautions and a quiet environment for at least 2 weeks.”

412. The nurse caring for a child diagnosed with rubeola (measles) notes that the pediatrician has documented the presence of Koplik’s spots. On the basis of this documentation, which observation is expected?

1. Pinpoint petechiae noted on both legs
2. Whitish vesicles located across the chest
3. Petechiae spots that are reddish and pinpoint on the soft palate
4. Small, blue-white spots with a red base found on the buccal mucosa

413. A mother of a child with mumps calls the health care clinic to tell the nurse that the child has been lethargic and vomiting. What instruction should the nurse give to the mother?

1. To continue to monitor the child
2. That lethargy and vomiting are normal with mumps
3. To bring the child to the clinic to be seen by the pediatrician
4. That, as long as there is no fever, there is nothing to be concerned about

414. The nurse is assessing a child admitted with a diagnosis of rheumatic fever. Which significant question should the nurse ask the child’s parent during the assessment?

1. “Has your child had difficulty urinating?”
2. “Has your child been exposed to anyone with chickenpox?”
3. “Has any family member had a sore throat within the past few weeks?”
4. “Has any family member had a gastrointestinal disorder in the past few weeks?”

415. The nurse is caring for a child diagnosed with erythemia infectiosum (fifth disease). Which clinical manifestation should the nurse expect to note in the child?

1. An intense fiery red edematous rash on the cheeks
2. Pinkish-rose maculopapular rash on the face, neck, and scalp
3. Reddish and pinpoint petechiae spots found on the soft palate
4. Small bluish-white spots with a red base found on the buccal mucosa
Answers

403. Answer: 1

**Rationale:** Acquired immunodeficiency syndrome (AIDS) is a disorder caused by HIV and characterized by generalized dysfunction of the immune system. The most common opportunistic infection of children infected with HIV is *Pneumocystis jiroveci* pneumonia, which occurs most frequently between the ages of 3 and 6 months, when HIV status may be indeterminate. Cough is a common sign of this opportunistic infection. Cytomegalovirus infection is also characteristic of HIV infection; however, it is not the most common opportunistic infection. Liver failure is a common sign of this complication. Although gastrointestinal disturbances and neurological abnormalities may occur in a child with HIV infection, options 3 and 4 are not specific opportunistic infections noted in the HIV-infected child. Watery stool is noted with gastroenteritis, and nuchal rigidity is seen in meningitis.

**Test-Taking Strategy:** Note the strategic word, *most*. This will direct you to the correct option. Remember that the most common opportunistic infection of children infected with HIV is *P. jiroveci* pneumonia, and that cough is a common sign with this complication.

**Level of Cognitive Ability:** Analyzing
**Client Needs:** Physiological Integrity
**Integrated Process:** Nursing Process — Assessment
**Content Area:** Pediatrics: Immune
**Health Problem:** Pediatric-Specific: Immunodeficiency disease
**Priority Concepts:** Clinical Judgment; Immunity
**Reference:** McKinney et al. (2018), pp. 938-939, 945.

404. Answer: 4

**Rationale:** AIDS is a disorder caused by human immunodeficiency virus (HIV) and characterized by generalized dysfunction of the immune system. A child with AIDS who is sick or has a fever should be kept home and not brought to a day care center. Options 1, 2, and 3 are correct statements and would be actions a caregiver should take when the child has AIDS.

**Test-Taking Strategy:** Note the strategic words, *need for further teaching*. These words indicate a negative event query and ask you to select an option that is an incorrect statement. Noting the word *fever* in the correct option will direct you to this option.

**Level of Cognitive Ability:** Evaluating
**Client Needs:** Safe and Effective Care Environment
**Integrated Process:** Teaching and Learning
**Content Area:** Pediatrics: Immune
**Health Problem:** Pediatric-Specific: Immunodeficiency disease
**Priority Concepts:** Client Education; Immunity
Rationale: Immunizations against common childhood illnesses are recommended for all children exposed to or infected with HIV. The inactivated influenza vaccine that is given intramuscularly will be administered (influenza vaccine should be given yearly). The hepatitis B vaccine is administered according to the recommended immunization schedule. Varicella-zoster virus vaccine should not be given, because it is a live virus vaccine; varicella-zoster immunoglobulin may be prescribed after chickenpox exposure. Option 4 is unnecessary and inaccurate.

Test-Taking Strategy: Focus on the subject, immunizations for the child with HIV. Option 4 can be eliminated first because the Western blot is a diagnostic test, not an evaluative test. From the remaining options, recalling that the child infected with HIV is at risk for opportunistic infections and that live virus vaccines are not administered to an immunodeficient child will assist in directing you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Health Promotion and Maintenance
Integrated Process: Teaching and Learning
Content Area: Pediatrics: Immune
Health Problem: Pediatric-Specific: Immunodeficiency disease
Priority Concepts: Client Education; Immunity

406. Answer: 4

Rationale: Infants born to HIV-infected mothers need to be screened for the HIV antigen. The detection of HIV in infants is confirmed by a p24 antigen assay, virus culture of HIV, or polymerase chain reaction. A Western blot test confirms the presence of HIV antibodies. The CD4+ cell count indicates how well the immune system is working. A chest x-ray evaluates the presence of other manifestations of HIV infection, such as pneumonia.

Test-Taking Strategy: Focus on the subject, laboratory study to determine the presence of HIV antigen, and note the word infant. Recall the laboratory tests used to determine the presence of HIV infection in the infant to answer this question.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Pediatrics: Immune
Health Problem: Pediatric-Specific: Immunodeficiency disease
Priority Concepts: Clinical Judgment; Immunity

407. Answer: 4

Rationale: Acquired immunodeficiency syndrome (AIDS) is caused by HIV infection and characterized by generalized dysfunction of the immune system. Most children infected with HIV develop symptoms within the first 9 months of life. The
remaining infected children become symptomatic sometime before age 3 years. With their immature immune systems, children have a much shorter incubation period than adults. Options 1, 2, and 3 are incorrect. Additionally, these options offer false reassurance.

Test-Taking Strategy: Note the strategic words, most appropriate. Eliminate options 1, 2, and 3 because they are comparable or alike in content. The correct option is the only one that provides specific and accurate data regarding HIV infection in an infant.

Level of Cognitive Ability: Applying
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Pediatrics: Immune
Health Problem: Pediatric-Specific: Immunodeficiency disease
Priority Concepts: Client Education; Immunity

Answer: 3

Rationale: The multiple complications associated with HIV are accompanied by a high level of pain. Aggressive pain management is essential for the child to have an acceptable quality of life. The nurse must acknowledge the child’s pain and let the child know that everything will be done to decrease the pain. Telling the child that movement or lack thereof would eliminate the pain is inaccurate. Allowing a child to think that he or she can control the pain simply by thinking or not thinking about it oversimplifies the pain cycle associated with HIV. Giving false hope by telling the child that the pain will be taken “all away” is neither truthful nor realistic.

Test-Taking Strategy: Note the strategic word, best. Recall the general concept of pain and growth and development concepts of a 6-year-old child. Giving the child information about the pain in words that he or she can understand, but without providing false hope or not telling the truth, should guide you to the correct option. Options 1 and 2 provide inaccurate information about pain management. Option 4 provides false hope that the pain can be alleviated completely.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Pediatrics: Immune
Health Problem: Pediatric-Specific: Immunodeficiency disease
Priority Concepts: Immunity; Pain

Answer: 1

Rationale: HIV is transmitted through blood, semen, vaginal secretions, and breast milk. The mother of an infant with HIV should be instructed to use a bleach solution for disinfecting contaminated objects or cleaning up spills from the child’s diaper. Alcohol would not be effective in destroying the virus. Options 2, 3, and 4 are accurate instructions related to basic infection control.
**Test-Taking Strategy:** Note the **strategic words**, *need for further instruction*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Recalling basic infection control measures and the measures to prevent the spread of HIV will direct you to the correct option.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Teaching and Learning

**Content Area:** Pediatrics: Infectious and Communicable Diseases

**Health Problem:** Pediatric-Specific: Immunodeficiency disease

**Priority Concepts:** Client Education; Infection

410. **Answer:** 1, 2, 3, 5

**Rationale:** AIDS is a disorder caused by human immunodeficiency virus (HIV) infection and is characterized by a generalized dysfunction of the immune system. Home care instructions include the following: frequent hand washing; monitoring for fever, malaise, fatigue, weight loss, vomiting, and diarrhea and notifying the pediatrician if these occur; monitoring for signs and symptoms of opportunistic infections; administering antiretroviral medications and other medications as prescribed; avoiding exposure to other illnesses; keeping immunizations up to date; monitoring weight and providing a high-calorie, high-protein diet; washing eating utensils in the dishwasher; and avoiding sharing eating utensils. Gloves are worn for care, especially when in contact with body fluids and changing diapers; diapers are changed frequently and away from food areas, and soiled disposable diapers are folded inward, closed with the tabs, and disposed of in a tightly covered plastic-lined container. Any body fluid spills are cleaned with a bleach solution (10:1 ratio of water to bleach).

**Test-Taking Strategy:** Focus on the **subject**, care of the child with AIDS. Recalling that AIDS is characterized by a generalized dysfunction of the immune system and recalling the modes of transmission of the virus will assist in selecting the correct home care instructions.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Teaching and Learning

**Content Area:** Pediatrics: Infectious and Communicable Diseases

**Health Problem:** Pediatric-Specific: Immunodeficiency disease

**Priority Concepts:** Client Education; Infection

411. **Answer:** 4

**Rationale:** Pertussis is transmitted by direct contact or respiratory droplets from coughing. The communicable period occurs primarily during the catarrhal stage. Respiratory precautions are not required during the convalescent phase. Options 1, 2, and 3 are accurate components of home care instructions.

**Test-Taking Strategy:** Note the **strategic words**, *need for further instruction*. These
words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Also, note the word *convalescent* in the question. Options 1 and 3 can be eliminated because they are generally associated with convalescence. Knowing that 2 weeks of respiratory precautions is not required during the convalescent period will direct you to this option.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Health Promotion and Maintenance  
**Integrated Process:** Teaching and Learning  
**Content Area:** Pediatrics: Infectious and Communicable Diseases  
**Health Problem:** Pediatric-Specific: Communicable Diseases  
**Priority Concepts:** Client Education; Infection  

412. **Answer:** 4

**Rationale:** In rubeola (measles), Koplik’s spots appear approximately 2 days before the appearance of the rash. These are small, blue-white spots with a red base that are found on the buccal mucosa. The spots last approximately 3 days, after which time they slough off. Based on this information, the remaining options are all incorrect.

**Test-Taking Strategy:** Eliminate options 1 and 3 that are **comparable or alike** and address petechiae spots. Focusing on the subject, Koplik’s spots, will direct you to the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process/Assessment  
**Content Area:** Pediatrics: Infectious and Communicable Diseases  
**Health Problem:** Pediatric-Specific: Communicable Diseases  
**Priority Concepts:** Clinical Judgment; Infection  

413. **Answer:** 3

**Rationale:** Mumps generally affects the salivary glands, but it can also affect multiple organs. The most common complication is septic meningitis, with the virus being identified in the cerebrospinal fluid. Common signs include nuchal rigidity, lethargy, and vomiting. The child should be seen by the pediatrician.

**Test-Taking Strategy:** Focus on the subject, a child with mumps who has been lethargic and vomiting. Recalling that meningitis is a complication of mumps will direct you to the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process/Implementation  
**Content Area:** Pediatrics: Infectious and Communicable/Diseases  
**Health Problem:** Pediatric-Specific: Communicable Diseases  
**Priority Concepts:** Clinical Judgment; Infection  
**Reference:** Hockenberry, Wilson, Rodgers (2017), pp. 150; 167; 656.
Rationale: Rheumatic fever characteristically presents 2 to 6 weeks after an untreated or partially treated group A beta-hemolytic streptococcal infection of the respiratory tract. Initially the nurse determines whether any family member has had a sore throat or unexplained fever within the past few weeks. The remaining options are unrelated to the assessment findings of rheumatic fever.

Test-Taking Strategy: Focus on the subject, rheumatic fever. Note the word significant. Recalling that rheumatic fever characteristically presents 2 to 6 weeks after a streptococcal infection of the respiratory tract will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process/Assessment
Content Area: Pediatrics: Infectious and Communicable Diseases
Health Problem: Pediatric-Specific: Rheumatic Fever
Priority Concepts: Clinical Judgment; Infection

Rationale: Fifth disease is characterized by the presence of an intense fiery red edematous rash on the cheeks, which gives an appearance that the child has been slapped. Options 2 and 3 are manifestations related to rubella (German measles). Koplik’s spots (option 4) are found in rubeola (measles).

Test-Taking Strategy: Focus on the subject, erythema infectiosum (fifth disease). Recalling the “slapped cheek” appearance associated with fifth disease will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process/Assessment
Content Area: Pediatrics: Infectious and Communicable Diseases
Health Problem: Pediatric-Specific: Communicable Diseases
Priority Concepts: Clinical Judgment; Infection
CHAPTER 41

Pediatric Medication Administration and Calculations

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Development; Safety

I. Oral Medications
   A. Most oral pediatric medications are in liquid or suspension form or chewable tablet form, because children usually are unable to swallow a tablet or capsule.
   B. Solutions may be measured by using an oral plastic syringe or other acceptable measurement or administration device; the device used depends on the developmental age of the child (Fig. 41-1).
   C. Medications in suspension settle to the bottom of the bottle between uses, and thorough mixing is required before pouring the medication.
   D. Suspensions must be administered immediately after measurement to prevent settling and resultant administration of an incomplete dose.
   E. Administer oral medications with a child sitting in an upright position and with the head elevated to prevent aspiration if the child cries or resists.
   F. Place a small child sideways on the lap; the child’s closest arm should be placed under the adult’s arm and behind the adult’s back; cradle the child’s head, hold the child’s hand, and administer the medication slowly with a plastic spoon, small plastic cup, or syringe.
   G. If a tablet or capsule has been administered, check the child’s mouth to ensure that it has been swallowed; if swallowing is a problem, some tablets can be crushed and given in small amounts of puréed food or flavored syrup (enteric-coated tablets, timed-release tablets, and capsules should not be crushed).
   H. Follow generally accepted medication administration guidelines for children (Box 41-1).
Newborns and infants have an immature liver and immature kidneys; therefore, metabolism and elimination of medications is delayed.

II. Parenteral Medications
   A. Subcutaneously and intramuscularly administered medications
      1. Medications most often given via the subcutaneous route are insulin and some immunizations.
      2. Any site with sufficient subcutaneous tissue may be used for subcutaneous injections; common sites include the central third of the lateral aspect of the upper arm, the abdomen, and the central third of the anterior thigh.
      3. The safe use of injection sites is based on normal muscle development and the size of the child; the preferred site for intramuscular injections in infants is the vastus lateralis, but agency policies and procedures need to be followed (Table 41-1 and Fig. 41-2).
      4. The usual needle length and gauge for pediatric clients are 0.5 to 1 inch (1.25 to 2.5 cm) and 22 to 25 gauge; needle length also can be estimated by grasping the muscle between the thumb and forefinger—half the resulting distance would be the needle length.
      5. Pediatric dosages for subcutaneous and intramuscular administration are calculated to the nearest hundredth and measured by using a tuberculin syringe; always follow agency guidelines.
   B. Intravenously administered medications
      1. Intravenous (IV) medications are diluted for administration.
      2. When an infant or child is receiving an IV medication, the IV site needs to be assessed for signs of inflammation and infiltration or extravasation immediately before, during, and after completion of each medication.
      3. IV medications may be prescribed in a manner that requires a continuous infusion through a primary infusion line.
      4. IV medications may be prescribed intermittently;
several doses may be administered in a 24-hour period.

5. Medications for IV administration are diluted according to the directions accompanying the medication and according to the pediatrician’s prescriptions and agency procedures.

6. Infusion time for IV medications is determined on the basis of the directions accompanying the medication, the pediatrician’s prescription, and agency procedures.

7. Determine agency procedures related to the volume of flush (normal saline) for peripheral IV lines and for central lines.

8. The flush volume (3 to 20 mL) must be included in the child’s intake; the flush is usually administered before administering an IV medication and after the IV medication is completed and is infused at the same rate as the medication.

C. Intermittent IV medication administration

1. Children receiving IV medications intermittently may or may not have a primary IV solution infusing.

2. If a primary IV solution is infusing, the medication may be administered by IV piggyback via a secondary line and via an infusion pump or infusion syringe device.

3. If a primary IV solution does not exist, an indwelling infusion catheter is used for medication administration, and the medication may be administered by push or piggyback; medication administration instructions must be checked for dilution and infusion time procedures.

4. All intermittent medication administrations are preceded and followed by a normal saline flush to ensure that the medication has cleared the IV tubing and that the total dose has been administered.

5. Electronic devices such as controllers or pumps are always used to regulate and administer IV fluids and intermittent IV medications.

D. Special IV administration sets

1. Special IV administration sets, such as a burette, may be used for medication preparation and administration via piggyback.

2. These special sets are all microdrip sets calibrated to deliver 60 drops (gtt)/mL.
3. The total capacity of these type of IV administration sets is 100 to 150 mL, calibrated in 1-mL increments so that exact measurements of small volumes are possible.

4. The medication is mixed with the appropriate amount of diluent, added to the IV administration set, and allowed to infuse at the prescribed rate.

5. The IV administration set needs to be labeled clearly to identify the medication and fluid dosage added.

6. During medication infusion time, a label (per agency guidelines) is attached that indicates that the medication is infusing.

7. During the flush infusion time, a label (per agency guidelines) is attached indicating that the flush is infusing.

E. Syringe pump for IV medication administration

1. A syringe containing the medication is fitted into a pump that is connected to the IV tubing through a Y connector.

2. The medication is administered over the prescribed time.

The 24-hour fluid intake must be monitored closely, and all IV fluid amounts including the amount of flush volume need to be documented accurately to prevent overhydration. For children, the maximum amount of IV fluid administered in a 24-hour period varies and is usually based on body weight and other factors. Check the prescription and agency guidelines for the procedures for the administration of IV fluids and medications.

III. Calculation of Medication Dosage by Body Weight

A. Conversion of body weight

1. There are many mobile application devices available to assist with calculating dosages, but it is important to know how to do these calculations without the use of a mobile device.

2. See Box 41-2 for body weight conversion.

B. Calculation of daily dosages based on weight

1. Abbreviations (Box 41-3)

2. Dosages are expressed in terms of milligrams per kilogram per day, milligrams per pound per day, or milligrams per kilogram per dose.

3. The total daily dosage usually is administered in divided (more than 1) doses per day as prescribed.

4. Express the child’s body weight in kilograms or
pounds to correlate with the dosage specifications.
5. Calculate the total daily dosage.
6. Divide the total daily dosage by the number of doses to be administered in 1 day.

IV. Calculation of Body Surface Area (BSA)
A. The BSA is determined by comparing body weight and height with averages or norms on a graph called a nomogram.
B. Not all children are the same size at the same age; the nomogram is used to determine the BSA of a child.
C. Look at the nomogram (Fig. 41-3) and note that the height is on the left-hand side of the chart and the weight is on the right-hand side of the chart.
D. Place a ruler across the chart.
E. Line up the left side of the ruler on the height and the right side of the ruler on the weight; read the BSA at the point where the straight edge of the ruler intersects the surface area (SA) column.
F. The estimated SA is given in square meters (m²).
G. Box 41-4 gives a sample practice question using the nomogram.

V. Calculation Based on BSA
A. When dosage recommendations for children specify milligrams, micrograms, or units per square meter, calculating the dosage is simple multiplication (Box 41-5).
B. When dosage recommendations are specified only for adults, a formula is used to calculate a child’s dosage from the adult dosage (Box 41-6).

VI. Developmental Considerations for Administering Medications
A. When administering medications to children, developmental age must be taken into consideration to ensure safe and effective administration.
B. General interventions
1. Always be prepared for the procedure with all necessary equipment and assistance.
2. For a hospitalized child, ask the parent or child or both as appropriate if the parent should or should not remain for the procedure.
3. Determine appropriate preadministration and postadministration comfort measures.
4. Try to make the event as pleasant as possible.
C. Box 41-7 lists developmental considerations when giving medications.
FIG. 41-1 Acceptable devices for measuring and administering oral medication to children (clockwise from bottom left): Measuring spoon, plastic syringes, calibrated nipple, plastic medicine cup, calibrated dropper, hollow-handled medicine spoon. (From Hockenberry, Wilson, 2005.)

Box 41-1

Medication Administration Guidelines for Children

- Two identifiers are required before medication administration—such as name, medical record number, and birth date. Bar code scanning systems are commonly used as an additional safeguard to ensure that medications are given to the correct client.
- Obtain information from parents about successful methods for administering medications to their children.
- Ask parents about any known allergies.
- To avoid aspiration, liquid forms of medication are safer to swallow than other forms.
- Straws often help older children to swallow pills.
- Avoid putting medications in foods such as milk, cereal, or baby food because it may cause an unpleasant taste to the food, and the child may refuse to accept the same food in the future. In addition, the child may not consume the entire
serving and would not receive the required medication dosage.

- If the taste of the medication is unpleasant, it is acceptable to have the child pinch the nose and drink the medication through a straw.
- Offer juice, a soft drink, or a frozen juice bar after the child swallows a medication.
- Always read the pharmacological indications for administration. Some items such as fruit syrups can be acidic and should not be used with medications that react negatively in an acid medium.
- Record the most successful method of administering medications and pertinent nursing prescriptions on the child’s care plan for other nursing staff to follow; this notation also saves the child frustration, fear, and anxiety.

FIG. 41-3 West nomogram for estimation of surface areas in infants and children. First, find height; next, find weight; finally, draw a straight line connecting the height and weight.
The body surface area (in square meters \(m^2\)) is indicated where a straight line connecting the height and weight intersects the surface area (SA) column or, if the child is approximately of normal proportion, from weight alone (darker blue area).

**Box 41-4**

**How to Use the Nomogram**

*Example:* Use the nomogram (see Fig. 41-3) and calculate the body surface area (BSA) for a child whose height is 58 inches (147 cm) and weight is 12 kg.

1. Look at the nomogram chart and note that the height is on the left-hand side of the chart and the weight is on the right-hand side.
2. Place a ruler on the chart and line up the left side of the ruler on the height and the right side of the ruler on the weight; read the BSA at the point where the straight edge of the ruler intersects the surface area (SA) column.
3. The estimated SA is given in square meters.

Answer:

\[0.66 \text{ m}^2\]

**Box 41-5**

**Calculating Medication Dosage**

When dosage recommendations for children specify milligrams, micrograms, or units per square meter, calculating the dosage is simple multiplication.

*Example:* The dosage recommendation is 4 mg/m\(^2\). The child has a body surface area of 1.1 m\(^2\). What is the dosage to be administered?

*Answer:*

\[1.1 \times 4 \text{ mg} = 4.4 \text{ mg}\]
Calculating a Child’s Dosage from the Adult Dosage

When dosages are specified only for adults, a formula is used to calculate a child’s dosage from the adult dosage. The adult dosage is based on a standardized body surface area (BSA) of 1.73 m$^2$.

**Example:** A pediatrician has prescribed an antibiotic for a child. The average adult dose is 250 mg. The child has a BSA of 0.41 m$^2$. What is the dose for the child?

**Answer:** 59.24 mg

**Formula:**

\[
\frac{\text{BSA of child (m}^2\text{)}}{1.73m^2} \times \text{Adult dose} = \text{Child’s dose}
\]

\[
\frac{0.41}{1.73} \times 250 \text{ mg} = 59.24 \text{ mg}
\]

---

**Box 41-7**

Developmental Considerations for Administering Medications

**Infants**

Perform procedure quickly, allowing the infant to swallow; then offer comfort measures, such as holding, rocking, and cuddling.

Allow self-comforting measures, such as the use of a pacifier.

**Toddlers**

Offer a brief, concrete explanation of the procedure and then perform it. Accept aggressive behavior, within reasonable limits, as a healthy response, and provide outlets for the toddler.

Provide comfort measures immediately after the procedure, such as touch, holding, cuddling, and providing a favorite toy.
Preschoolers

Offer a brief, concrete explanation of the procedure and then perform it. Accept aggressive behavior, within reasonable limits, as a healthy response, and provide outlets for the child. Provide comfort measures after the procedure, such as touch, holding, or providing a favorite toy.

School-Age Children

Explain the procedure, allowing for some control over the body and situation. Explore feelings and concepts through therapeutic play, drawings of own body and self in the hospital, and the use of books and realistic hospital equipment. Set appropriate behavior limits, such as it is all right to cry or scream, but not to bite. Provide activities for releasing aggression and anger. Use the opportunity to teach about how medication helps the disorder.

Adolescents

Explain the procedure, allowing for some control over body and situation. Explore concepts of self, hospitalization, and illness, and correct any misconceptions. Encourage self-expression, individuality, and self-care needs. Encourage participation in the procedure.

Data from McKenry L, Salerno E: Mosby's pharmacology in nursing, St. Louis, 2003, Mosby.

Practice Questions

416. The nurse is providing medication instructions to a parent. Which statement by the parent indicates a need for further instruction?  
   1. “I should cuddle my child after giving the medication.”
   2. “I can give my child a frozen juice bar after he swallows the medication.”
   3. “I should mix the medication in the baby food and give it when I feed my child.”
   4. “If my child does not like the taste of the medicine, I should encourage him to pinch his nose and drink the medication through a straw.”

417. A pediatrician’s prescription reads “ampicillin sodium 125 mg IV every 6 hours.” The medication label reads “when reconstituted with 7.4 mL of bacteriostatic water, the final concentration is 1 g/7.4 mL.” The nurse prepares to draw up how many milliliters to administer 1 dose?
1. 1.1 mL  
2. 0.54 mL  
3. 7.425 mL  
4. 0.925 mL

418. A pediatric client with ventricular septal defect repair is placed on a maintenance dosage of digoxin. The dosage is 8 mcg/kg/day, and the client’s weight is 7.2 kg. The pediatrician prescribes the digoxin to be given twice daily. The nurse prepares how many mcg of digoxin to administer to the child at each dose?  
   1. 12.6 mcg  
   2. 21.4 mcg  
   3. 28.8 mcg  
   4. 32.2 mcg

419. Sulfisoxazole, 1 g orally twice daily, is prescribed for an adolescent with a urinary tract infection. The medication label reads “500-mg tablets.” The nurse has determined that the dosage prescribed is safe. The nurse administers how many tablets per dose to the adolescent?  
   1. ½ tablet  
   2. 1 tablet  
   3. 2 tablets  
   4. 3 tablets

420. Penicillin G procaine, 1,000,000 units IM (intramuscularly), is prescribed for an adolescent with an infection. The medication label reads “1,200,000 units per 2 mL.” The nurse has determined that the dose prescribed is safe. The nurse administers how many milliliters per dose to the adolescent? Round answer to the nearest tenth position.  
   1. 0.8 mL  
   2. 1.2 mL  
   3. 1.4 mL  
   4. 1.7 mL

421. The nurse prepares to administer an intramuscular injection to a 4-month-old infant. The nurse selects which best site to administer the injection?  
   1. Ventrogluteal  
   2. Lateral deltoid  
   3. Rectus femoris  
   4. Vastus lateralis

422. Atropine sulfate, 0.6 mg intramuscularly, is prescribed for a child preoperatively. The nurse has determined that the dose prescribed is safe and prepares to administer how many milliliters to the child? Fill in the blank (refer to figure).
Answer: ______ mL

Answers

416. Answer: 3

Rationale: The nurse would teach the parent to avoid putting medications in foods because it may give an unpleasant taste to the food, and the child may refuse to accept the same food in the future. In addition, the child may not consume the entire serving and would not receive the required medication dosage. The mother should provide comfort measures immediately after medication administration, such as touching, holding, cuddling, and providing a favorite toy. The mother should offer juice, a soft drink, or a frozen juice bar to the child after the child swallows the medication. If the taste of the medication is unpleasant, the child should pinch the nose and drink the medication through a straw.

Test-Taking Strategy: Note the strategic words, need for further instruction. These words indicate a negative event query and the need to select the incorrect statement made by the mother. Read each statement carefully and think about the statement that may be unsafe and may not provide an accurate dose to the child. This will direct you to the correct option.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Skills: Client Teaching
Health Problem: N/A
Priority Concepts: Client Education; Safety

417. Answer: 4

Rationale: Convert 1 g to milligrams. In the metric system, to convert larger to smaller, multiply by 1000 or move the decimal point 3 places to the right:
Formula:

\[
\frac{\text{Desired}}{\text{Available}} \times \text{Volume} = \frac{125 \text{ mg}}{1000 \text{ mg}} \times 7.4 \text{ mL} = 0.925 \text{ mL per dose}
\]

Test-Taking Strategy: Focus on the subject, milliliters per dose. Convert grams to milligrams first. Next, use the formula to determine the correct dose, knowing that when reconstituted, 1000 mg = 7.4 mL. Verify the answer using a calculator.

Level of Cognitive Ability: Applying

Client Needs: Physiological Integrity

Integrated Process: Nursing Process—Implementation

Content Area: Skills: Dosage Calculations

Health Problem: N/A

Priority Concepts: Clinical Judgment; Safety

418. Answer: 3

Rationale: Calculate the daily dosage by weight first:

\[8 \text{ mcg} \times 7.2 \text{ kg} = 57.6 \text{ mcg / day}\]

The pediatrician prescribes digoxin twice daily; 2 doses in 24 hours will be administered:

\[\frac{57.6 \text{ mcg / day}}{2 \text{ doses}} = 28.8 \text{ mcg for each dose}\]

Test-Taking Strategy: Focus on the subject, mcg per dose, and note that the question states twice daily and each dose. Calculate the dosage per day by weight first, and then determine the micrograms per each dose by dividing the total daily dose.
by 2. Verify the answer using a calculator.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Skills: Dosage Calculations  
**Health Problem:** Pediatric-Specific: Congenital Cardiac Defects  
**Priority Concepts:** Clinical Judgment; Safety  

419. **Answer:** 3

**Rationale:** Change 1 g to milligrams, knowing that 1000 mg = 1 g. Also, when converting from grams to milligrams (larger to smaller), move the decimal point 3 places to the right:

\[
1 \text{ g} = 1000 \text{ mg}
\]

Next, use the formula to calculate the correct dose.  
**Formula:**

\[
\frac{\text{Desired}}{\text{Available}} \times \text{Tablet} = \frac{1000 \text{ mg}}{500 \text{ mg}} \times \text{Tablet} = 2 \text{ tablets}
\]

**Test-Taking Strategy:** Focus on the subject, tablets per dose. Convert grams to milligrams first. Next, use the formula to determine the correct dose and verify the answer using a calculator.  
**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Skills: Dosage Calculations  
**Health Problem:** N/A  
**Priority Concepts:** Clinical Judgment; Safety  
**Reference:** Potter et al. (2017), pp. 620-621.

420. **Answer:** 4

**Rationale:** Use the medication calculation formula.  
**Formula:**
Test-Taking Strategy: Focus on the **subject**, milliliters per dose. Use the formula to determine the correct dose, and verify the answer using a calculator.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Skills: Dosage Calculations  
**Health Problem:** N/A  
**Priority Concepts:** Clinical Judgment; Safety  
**Reference:** Potter et al. (2017), pp. 620-621.

421. **Answer:** 4

**Rationale:** Intramuscular injection sites are selected on the basis of the child’s age and muscle development of the child. The vastus lateralis is the only safe muscle group to use for intramuscular injection in a 4-month-old infant. The sites identified in options 1, 2, and 3 are unsafe for a child of this age.

Test-Taking Strategy: Note the **strategic word**, **best**, and focus on the age of the child identified in the question. Thinking about the physiological development of the muscle groups in an infant at 4 months of age will assist in directing you to the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Skills: Medication Administration  
**Health Problem:** N/A  
**Priority Concepts:** Clinical Judgment; Safety  

422. **Answer:** 1.5

**Rationale:** Use the formula for calculating the medication dose.  
**Formula:**

\[
\frac{\text{Desired}}{\text{Available}} \times Volume = \frac{1,000,000}{1,200,000} \times 2 \text{ mL} = 1.66 = 1.7 \text{ mL per dose}
\]

\[
\frac{\text{Desired}}{\text{Available}} \times Volume = \frac{0.6 \text{ mg}}{0.4 \text{ mg}} \times 1 \text{ mL} = 1.5 \text{ mL}
\]
**Test-Taking Strategy:** Focus on the **subject**, the milliliters to be administered. Note that the medication label indicates that there is 0.4 mg/mL. Use the formula to determine the correct dose, and verify the answer using a calculator.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Skills: Dosage Calculations

**Health Problem:** N/A

**Priority Concepts:** Clinical Judgment; Safety

**Reference:** Potter et al. (2017), pp. 620-621.
UNIT VII
Integumentary Problems of the Adult Client
Introduction

Pyramid to Success

The Pyramid to Success focuses on the concept that the integumentary system provides the first line of defense against infections. Focus is on the protective measures necessary to prevent infection, including infection from colonization with a multidrug-resistant organism, such as methicillin-resistant \textit{Staphylococcus aureus} (MRSA). Pyramid Points address the risk factors related to the development of integumentary problems, and the preventive measures related to these problems, including skin cancer. Another important focus are the emergency measures related to bites and stings. Psychosocial issues related to the body image disturbances that can occur as the result of an integumentary problem and providing psychosocial support is a primary nursing consideration.

Client Needs: Learning Objectives

Safe and Effective Care Environment

- Consulting with interprofessional health care team members regarding treatments
- Ensuring that informed consent has been obtained for treatments and procedures
- Establishing priorities of care
- Handling of hazardous and infectious materials
- Instituting standard and other precautions
- Maintaining confidentiality related to the skin problem
- Making referrals to appropriate interprofessional health care team members
- Practicing asepsis techniques and preventing infection

Health Promotion and Maintenance

- Implementing disease prevention measures
- Performing physical assessment techniques for the integumentary system
- Promoting health screening and health promotion programs to prevent skin problems
- Providing instructions to the client regarding prevention measures and care for an integumentary problem
Psychosocial Integrity

- Addressing end-of-life issues
- Discussing unexpected body image changes
- Identifying coping mechanisms
- Identifying situational role changes
- Identifying support systems
- Providing support to the client to assist in coping with the integumentary problem

Physiological Integrity

- Assessing for alterations in body systems
- Providing adequate nutrition for healing
- Providing basic care and comfort
- Providing emergency care for an integumentary injury such as a bite or sting
- Monitoring for expected effects of treatments
- Monitoring for fluid and electrolyte imbalances and other complications
- Monitoring laboratory reference intervals
CHAPTER 42

Integumentary Problems

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Infection; Tissue Integrity

I. Anatomy and Physiology
   A. The skin is the largest sensory organ of the body, with a surface area of 15 to 20 square feet (1.4 to 1.9 square meters) and a weight of about 9 lb (4 kg).
   B. Functions
      1. Acts as the first line of defense against infections
      2. Protects underlying tissues and organs from injury
      3. Receives stimuli from the external environment; detects touch, pressure, pain, and temperature stimuli; relays information to the nervous system
      4. Regulates normal body temperature
      5. Excretes salts, water, and organic wastes
      6. Protects the body from excessive water loss
      7. Synthesizes vitamin D₃, which converts to calcitriol, for normal calcium metabolism
      8. Stores nutrients
   C. Layers
      1. Epidermis
      2. Dermis
      3. Hypodermis (subcutaneous fat)
   D. Epidermal appendages
      1. Nails
      2. Hair
      3. Glands
         a. Sebaceous
         b. Sweat
   E. Normal bacterial flora
      1. Types of normal bacterial flora include:
         a. Gram-positive and gram-negative staphylococci

1205
b. *Pseudomonas*

c. *Streptococcus*

2. Organisms are shed with normal exfoliation.

3. A pH of 4.2 to 5.6 halts the growth of bacteria.

II. Risk Factors for Integumentary Problems

A. Exposure to chemical and environmental pollutants
B. Exposure to radiation
C. Race and age
D. Exposure to the sun or use of indoor tanning
E. Lack of personal hygiene habits
F. Use of harsh soaps or other harsh products
G. Some medications, such as long-term glucocorticoid use or herbal preparations
H. Nutritional deficiencies
I. Moderate to severe emotional stress
J. Infection, with injured areas as the potential entry points for infection
K. Repeated injury and irritation
L. Genetic predisposition
M. Systemic illnesses

III. Psychosocial Impact

A. Change in body image, decreased general well-being, and decreased self-esteem
B. Social isolation and fear of rejection (because of embarrassment about changes in skin appearance)
C. Restrictions in physical activity
D. Pain
E. Disruption or loss of employment
F. Cost of medications, hospitalizations, and follow-up care, including dressing supplies

IV. Phases of Wound Healing

A. Phases

1. Inflammatory: Begins at the time of injury and lasts 3 to 5 days; manifestations include local edema, pain, redness, and warmth.
2. Fibroblastic: Begins the fourth day after injury and lasts 2 to 4 weeks; scar tissue forms and granulation tissue forms in the tissue bed.
3. Maturation: Begins as early as 3 weeks after the injury and may last for 1 year; scar tissue becomes thinner and is firm and inelastic on palpation.

B. Healing by intention

1. First intention: Wound edges are approximated and held in place (i.e., with sutures) until healing occurs; wound is easily closed and dead space is eliminated.
2. Second intention: This type of healing occurs with injuries or wounds that have tissue loss and require gradual filling in of the dead space with connective tissue.

3. Third intention: This type of healing involves delayed primary closure and occurs with wounds that are intentionally left open for several days for irrigation or removal of debris and exudates; once debris has been removed and inflammation resolves, the wound is closed by first intention.

C. Types of wound drainage: Refer to Box 42-1.

V. Diagnostic Tests

A. Skin biopsy

1. Description
   a. Skin biopsy is the collection of a small piece of skin tissue for histopathological study.
   b. Methods include punch, excisional, and shave.

2. Preprocedure interventions
   a. Verify informed consent has been obtained.
   b. Cleanse site as prescribed.

3. Postprocedure interventions
   a. Place specimen in the appropriate container and send to pathology laboratory for analysis.
   b. Use surgically aseptic technique for biopsy site dressings.
   c. Assess the biopsy site for bleeding and infection.
   d. Instruct the client to keep dressing in place for at least 8 hours, and then clean daily and use antibiotic ointment as prescribed (sutures are usually removed in 7 to 10 days).
   e. Instruct the client to report signs of excessive drainage, redness, or other signs of infection.

B. Skin/wound cultures

1. A small skin culture sample is obtained with a sterile applicator and the appropriate type of culture tube (e.g., bacterial or viral). Methods include scraping, punch biopsy, and collecting fluid. Local anesthesia may be used.
2. A nasal swab is also commonly done to determine previous exposure to certain types of bacteria.
3. Postprocedure intervention
   a. Viral culture is placed immediately on ice.
   b. Sample is sent to the laboratory to identify an existing organism.

C. Wood’s light examination
   1. Description: Skin is viewed under ultraviolet light through a special glass (Wood’s glass) to identify superficial infections of the skin.
   2. Preprocedure intervention: Explain procedure to the client and reassure him or her that the light is not harmful to the skin or the eyes. Darken the room before the examination.
   3. Postprocedure intervention: Assist the client during adjustment from the darkened room.

D. Diascopy
   1. Technique allows clearer inspection of lesions by eliminating the erythema caused by increased blood flow to the area.
   2. A glass slide is pressed over the lesion, causing blanching and revealing the lesion more clearly.

E. Skin assessment: See Chapter 12.

VI. Candida albicans
   A. Description
      1. A superficial fungal infection of the skin and mucous membranes
      2. Also known as a yeast infection (oral candidiasis), or thrush when it occurs in the mouth
      3. Risk factors include immunosuppression, long-term antibiotic therapy, diabetes mellitus, and obesity.
      4. Common areas of occurrence include skin folds, perineum, vagina, axilla, and under the breasts.

B. Assessment
   1. Skin: Red and irritated appearance that itches and stings
   2. Mucous membranes of the mouth: Red and whitish patches

C. Interventions
   1. Teach the client to keep skin fold areas clean and dry.
   2. For the hospitalized client, inspect skin fold areas frequently, turn and reposition the client frequently,
and keep the skin and bed linens clean and dry.
3. Provide frequent mouth care as prescribed and avoid
irritating products.
4. Provide food and fluids that are tepid in temperature
and nonirritating to mucous membranes.
5. Antifungal medications may be prescribed.

VII. Herpes Zoster (Shingles)

A. Description
1. With a history of chickenpox, shingles is caused by
reactivation of the varicella zoster virus; shingles can
occur during any immunocompromised state in a
client with a history of chickenpox.
2. The dormant virus is located in the dorsal nerve root
ganglia of the sensory cranial and spinal nerves.
3. Herpes zoster eruptions occur in a segmental
distribution on the skin area along the infected nerve
and show up after several days of discomfort in the
area.
4. Diagnosis is determined by visual examination and by
Tzanck smear to verify a herpes infection and viral
culture to identify the organism.
5. Postherpetic neuralgia (severe pain) can remain after
the lesions resolve.
6. Herpes zoster is contagious to individuals who never
had chickenpox and who have not been vaccinated
against the disease.
7. Herpes simplex virus is another type of virus; type 1
infection typically causes a cold sore (usually on the
lip) and type 2 causes genital herpes typically below
the waist (both types are contagious and may be
present together).

B. Assessment
1. Unilaterally clustered skin vesicles along peripheral
sensory nerves on the trunk, thorax, or face
2. Fever, malaise
3. Burning and pain
4. Paresthesia
5. Pruritus

C. Interventions
1. Isolate the client, because exudate from the lesions
contains the virus (maintain standard and other
precautions as appropriate, such as contact
precautions, as long as vesicles are present).
2. Assess for signs and symptoms of infection, including
skin infections and eye infections; skin necrosis can
also occur.
3. Assess neurovascular status and seventh cranial nerve
function; Bell’s palsy is a complication.
4. Use an air mattress and bed cradle on the client’s bed if hospitalized, and keep the environment cool; warmth and touch aggravate the pain.
5. Prevent the client from scratching and rubbing the affected area.
6. Instruct the client to wear lightweight, loose cotton clothing and to avoid wool and synthetic clothing.
7. Teach the client about the prescribed therapies; astringent compresses may be prescribed to relieve irritation and pain and to promote crust formation and healing.
8. Teach the client about measures to keep the skin clean to prevent infection.
9. Teach the client about topical treatment and antiviral medications; antiviral therapies begun within 3 days of rash reduce pain and lessen likelihood of postherpetic neuralgia.
10. The vaccination for shingles, is recommended for adults 50 years of age and older to reduce the risk of occurrence and the associated long-term pain.
11. Antiviral medications may be prescribed; refer to Chapter 63 for information on antiviral medications.

VIII. Methicillin-Resistant Staphylococcus aureus (MRSA)

A. Description
1. Skin or wound becomes infected with methicillin-resistant Staphylococcus aureus (MRSA). MRSA can be community acquired, such as through sports when skin-to-skin contact and sharing of equipment occurs. It can also be hospital acquired, such as in the case of a surgical site infection (SSI). See Chapter 13 for additional types of health care–associated infections.
2. An MRSA screening with a nasal swab may be done for clients who are having surgery, who have been previously hospitalized, or who live in group settings. Clients with positive cultures or with a history of a positive culture are isolated.
3. Infection can range from mild to severe and can present as folliculitis or furuncles.
4. Folliculitis is a superficial infection of the follicle caused by Staphylococcus and presents as a raised red rash and pustules; furuncles are also caused by Staphylococcus and occur deep in the follicle, presenting as very painful large, raised bumps that may or may not have a pustule.
5. If MRSA infects the blood, sepsis, organ damage, and death can occur.
MRSA is contagious and is spread to others by direct contact with infected skin or infected articles; for the client with MRSA, the infection can also be spread to many parts of the body.

B. Assessment: A culture and sensitivity test of the skin or wound confirms the presence of MRSA and leads to choice of appropriate antibiotic therapy.

C. Interventions

1. Maintain standard precautions and contact precautions as appropriate to prevent spread of infection to others.
2. Monitor the client closely for signs of further infection, which may result in systemic illness or organ damage.
3. Administer antibiotic therapy as prescribed.
4. For additional information on MRSA, refer to Chapters 13 and 40.

IX. Erysipelas and Cellulitis

A. Description

1. Erysipelas is an acute, superficial, rapidly spreading inflammation of the dermis and lymphatics caused by group A Streptococcus, which enters the tissue via an abrasion, bite, trauma, or wound.
2. Cellulitis is an infection of the dermis and underlying hypodermis; the causative organism is usually group A Streptococcus or Staphylococcus aureus.

B. Assessment

1. Pain and tenderness
2. Erythema and warmth
3. Edema
4. Fever

C. Interventions

1. Promote rest of the affected area.
2. Apply warm compresses as prescribed to promote circulation and to decrease discomfort, erythema, and edema.
3. Apply antibacterial dressings, ointments, or gels as prescribed.
4. Administer antibiotics as prescribed for an infection; obtain a culture of the area before initiating the antibiotics.

X. Poison Ivy, Poison Oak, and Poison Sumac

A. Description: A dermatitis that develops from contact with urushiol from poison ivy, oak, or sumac plants

B. Assessment

1. Papulovesicular lesions
2. Severe pruritus

C. Interventions
1. Cleanse the skin of the plant oils immediately.
2. Apply cool, wet compresses to relieve the itching.
3. Apply topical products to relieve the itching and discomfort.
4. Topical or oral glucocorticoids may be prescribed for severe reactions.

XI. Bites and Stings

A. Spider bites

1. Almost all types of spider bites are venomous and most are not harmful, but bites or stings from brown recluse spiders, black widow spiders, and tarantulas (as well as from scorpions, bees, and wasps) can produce toxic reactions in humans. Tetanus prophylaxis should be current because spider bites can be contaminated with tetanus spores.

2. Brown recluse spider
   a. Bite can cause a skin lesion, a necrotic wound, or systemic effects from the toxin (loxoscelism).
   b. Application of ice decreases enzyme activity of the venom and limits tissue necrosis; should be done immediately and intermittently for up to 4 days after the bite.
   c. Topical antiseptics and antibiotics may be necessary if the site becomes infected.

3. Black widow spider
   a. Bite causes a small red papule.
   b. Venom causes neurotoxicity.
   c. Ice is applied immediately to inhibit the action of the neurotoxin.
   d. Systemic toxicity can occur, and the victim may require supportive therapy in the hospital.

4. Tarantulas
   a. Bite causes swelling, redness, numbness, lymph inflammation, and pain at the bite site.
   b. The tarantula launches its barbed hairs, which can penetrate the skin and eyes of the victim, producing a severe inflammatory reaction.
   c. Tarantula hairs are removed as soon as possible, using sticky tape to pull hairs...
from the skin, and the skin is thoroughly irrigated; saline irrigations are done for eye exposure.
d. The involved extremity is elevated and immobilized to reduce pain and swelling.
e. Antihistamines and topical or systemic corticosteroids may be prescribed; tetanus prophylaxis is necessary.

B. Scorpion stings
1. Scorpions inject venom into the victim through a stinging apparatus on their tail.
2. Most stings cause local pain, inflammation, and mild systemic reactions that are treated with analgesics, wound care, and supportive treatment.
3. The bark scorpion can inflict a severe and potentially fatal systemic response, especially in children and the elderly; the venom is neurotoxic; the victim should be taken to the emergency department immediately (an antivenom is administered for bark scorpion bites).

C. Bees and wasps
1. Stings usually cause a wheal and flare reaction.
2. Emergency care involves quick removal of the stinger and application of an ice pack.
3. The stinger is removed by gently scraping or brushing it off with the edge of a needle or similar object; tweezers are not used because there is a risk of pinching the venom sac.
4. If the victim is allergic to the venom of a bee or wasp, a severe allergic response can occur (hives, pruritus, swelling of the lips and tongue) that can progress to life-threatening anaphylaxis; immediate emergency care is required.
5. Individuals who are allergic should carry an epinephrine autoinjector for self-administration of intramuscular epinephrine if a bee or wasp sting occurs. After use of the epinephrine autoinjector, the individual should seek emergency medical attention. Persons should have 2 injectors available and obtain a replacement as soon as possible.

D. Snake bites
1. Some snakes are venomous and can cause a serious systemic reaction in the victim.
2. The victim should be immediately moved to a safe area away from the snake and should rest to decrease venom circulation; the extremity is immobilized and kept below the level of the heart.
3. Constricting clothing and jewelry are removed before
swelling occurs.
4. The victim is kept warm and is not allowed to consume caffeinated or alcoholic beverages, which may speed absorption of the venom.
5. If unable to seek emergency medical attention promptly, a constricting band may be applied proximal to the wound to slow the venom circulation; monitor the circulation frequently and loosen the band if edema occurs.
6. The wound is not incised or sucked to remove the venom; ice is not applied to the wound.
7. Emergency care in a hospital is required as soon as possible; an antivenom may be administered along with supportive care. The snake should not be transported with the victim for identification purposes unless it can be safely placed in a sealed container during transportation.

For spider bites, scorpion bites, or other stings or bites, the Poison Control Center should be contacted as soon as possible to determine the best initial management.

XII. Frostbite
A. Description
1. Frostbite is damage to tissues and blood vessels as a result of prolonged exposure to cold.
2. Fingers, toes, face, nose, and ears often are affected.

B. Assessment
1. First-degree: Involves white plaque surrounded by a ring of hyperemia and edema
2. Second-degree: Large, clear fluid-filled blisters with partial-thickness skin necrosis
3. Third-degree: Involves the formation of small hemorrhagic blisters, usually followed by eschar formation involving the hypodermis requiring debridement
4. Fourth-degree: No blisters or edema noted; full-thickness necrosis with visible tissue loss extending into muscle and bone, which may result in gangrene. Amputation may be required.

C. Interventions
1. Rewarm the affected part rapidly and continuously with a warm water bath or towels at 104.0° F to 107.6° F (40° C to 42° C) to thaw the frozen part.
2. Handle the affected area gently and immobilize.
3. Avoid using dry heat, and never rub or massage the
part, which may result in further tissue damage.
4. The rewarming process may be painful; analgesics may be necessary.
5. Avoid compression of the injured tissues and apply only loose and nonadherent sterile dressings.
6. Monitor for signs of compartment syndrome.
7. Tetanus prophylaxis is necessary, and topical and systemic antibiotics may be prescribed.
8. Debridement of necrotic tissue may be needed; amputation may be necessary if gangrene develops.

XIII. Actinic Keratoses
A. Actinic keratoses are caused by chronic exposure to the sun and appear as rough, scaly, red, or brown lesions that are usually found on the face, scalp, arms, and backs of the hands.
B. Lesions are considered premalignant, and there is risk for slow progression to squamous cell carcinoma.
C. Treatment includes medications, excision, cryotherapy, curettage, and laser therapy.
D. See Chapter 43 for information on medications to treat this disorder.

XIV. Skin Cancer
A. Description
1. Skin cancer is a malignant lesion of the skin, which may or may not metastasize.
2. Overexposure to the sun is a primary cause; other causes and conditions that place the individual at risk include chronic skin damage from repeated injury and irritation such as tanning and use of tanning beds, genetic predisposition, ionizing radiation, light-skinned race, age older than 60 years, an outdoor occupation, and exposure to chemical carcinogens.
3. Diagnosis is confirmed by skin biopsy.

B. Types
1. Basal cell: Basal cell cancer arises from the basal cells contained in the epidermis; metastasis is rare, but underlying tissue destruction can progress to organ tissue.
2. Squamous cell: Squamous cell cancer is a tumor of the epidermal keratinocytes and can infiltrate surrounding structures and metastasize to lymph nodes.
3. Melanoma: Melanoma may occur any place on the body, especially where birthmarks or new moles are apparent; it is highly metastatic to the brain, lungs, bone, and liver, with survival depending on early diagnosis and treatment.

C. Assessment (see Box 42-2)
1. Change in color, size, or shape of preexisting lesion  
2. Pruritus  
3. Local soreness

The client needs to be informed about the risks associated with overexposure to the sun and taught about the importance of performing monthly skin self-assessments.

D. Interventions

1. Instruct the client regarding the risk factors and preventive measures.
2. Instruct the client to perform monthly skin self-assessments and to monitor for lesions that do not heal or that change characteristics.
3. Advise the client to have moles or lesions that are subject to chronic irritation removed.
4. Advise the client to avoid contact with chemical irritants.
5. Instruct the client to wear layered clothing and use and reapply sunscreen lotions with an appropriate sun protection factor when outdoors.
6. Instruct the client to avoid sun exposure between 10 a.m. and 4 p.m.
7. Management may include surgical or nonsurgical interventions; if medication is prescribed, provide instructions about its use.
8. Assist with surgical management, which may include cryosurgery, curettage and electrodessication, or surgical excision of the lesion.

XV. Psoriasis

A. Description

1. Psoriasis is a chronic, noninfectious skin inflammation occurring with remissions and exacerbations involving keratin synthesis that results in psoriatic patches; it may lead to an infection in the affected area.
2. Various forms exist, with psoriasis vulgaris being the most common.
3. Possible causes of the disorder include stress, trauma, infection, hormonal changes, obesity, an autoimmune reaction, and climate changes; a genetic predisposition may also be a cause.
4. The disorder may be exacerbated by the use of certain medications.
5. Koebner phenomenon is the development of psoriatic lesions at a site of injury, such as a scratched or
sunburned area. Prompt cleansing of the area may prevent or lessen this phenomenon.

6. In some individuals with psoriasis, arthritis develops, which leads to joint changes similar to those seen in rheumatoid arthritis.

7. The goal of therapy is to reduce cell proliferation and inflammation, and the type of therapy prescribed depends on the extent of the disease and the client’s response to treatment.

B. Assessment

1. Pruritus
2. Shedding: Silvery-white scales on a raised, reddened, round plaque that usually affects the scalp, knees, elbows, extensor surfaces of arms and legs, and sacral regions
3. Yellow discoloration, pitting, and thickening of the nails are noted if they are affected.
4. Joint inflammation with psoriatic arthritis

C. Pharmacological therapy: Refer to Chapter 43 for medications used to treat psoriasis.

D. Interventions and client education

1. Provide emotional support to the client with associated altered body image and decreased self-esteem.
2. Instruct the client in the use of prescribed therapies and to avoid over-the-counter medications.
3. Instruct the client not to scratch the affected areas and to keep the skin lubricated as prescribed to minimize itching.
4. Monitor for and instruct the client to recognize and report the signs and symptoms of secondary skin problems, such as infection.
5. Instruct the client to wear light cotton clothing over affected areas.
6. Assist the client to identify ways to reduce stress if stress is a predisposing factor.

XVI. Acne Vulgaris

A. Description

1. Acne is a chronic skin disorder that usually begins in puberty and is more common in males; lesions develop on the face, neck, chest, shoulders, and back.
2. Acne requires active treatment for control until it resolves.
3. The types of lesions include comedones (open and closed), pustules, papules, and nodules.
4. The exact cause is unknown but may include androgenic influence on sebaceous glands, increased
sebum production, and proliferation of *Propionibacterium acnes*, the organism that converts sebum into irritant fatty acids.

5. Exacerbations coincide with the menstrual cycle in female clients because of hormonal activity; oily skin and a genetic predisposition may be contributing factors.

B. Assessment

1. Closed comedones are whiteheads and noninflamed lesions that develop as follicles enlarge, with the retention of horny cells.
2. Open comedones are blackheads that result from continuing accumulation of horny cells and sebum, which dilates the follicles.
3. Pustules and papules result as the inflammatory process progresses.
4. Nodules result from total disintegration of a comedone and subsequent collapse of the follicle.
5. Deep scarring can result from nodules.

C. Interventions

1. Instruct the client in prescribed skin-cleansing methods, with emphasis on not scrubbing the face and using only prescribed topical agents.
2. Instruct the client in the administration of topical or oral medications as prescribed.
3. Instruct the client not to squeeze, prick, or pick at lesions.
4. Instruct the client to use products labeled noncomedogenic and cosmetics that are water based and to avoid contact with products with an excessive oil base.
5. Instruct the client on the importance of follow-up treatment.
6. Refer to Chapter 43 for information on the medications used to treat acne.

XVII. Stevens-Johnson Syndrome

A. A medication-induced skin reaction that occurs through an immunological response; common medications causing the reaction include antibiotics (especially sulfonamides), antiseizure medications, and nonsteroidal antiinflammatory drugs (NSAIDs).

B. Similar to toxic epidermal necrolysis (TEN), another medication-induced skin reaction that results in diffuse erythema and large blister formation on the skin and mucous membranes

C. May be mild or severe, and may cause vesicles, erosions, and crusts on the skin; if severe, systemic reactions occur that involve the respiratory system, renal system, and eyes, resulting in blindness, and it can be fatal. Initial clinical manifestations include
flu-like symptoms and erythema of the skin and mucous membranes. Serious systemic symptoms and complications occur when the ulcerations involve the larynx, bronchi, and esophagus.

D. Most commonly occurs in clients who have impaired immune systems

E. Treatment includes immediate discontinuation of the medication causing the syndrome; antibiotics, corticosteroids, and supportive therapy may be necessary.

XVIII. Pressure Injury

A. Description

1. A pressure injury is an impairment of skin integrity.
2. A pressure injury can occur anywhere on the body; tissue damage results when the skin and underlying tissue are compressed between a bony prominence and an external surface for an extended period.
3. The tissue compression restricts blood flow to the skin, which can result in tissue ischemia, inflammation, and necrosis; once a pressure injury forms, it is difficult to heal.
4. Prevention of skin breakdown in any part of the client’s body is a major role for the nurse.

B. Risk factors

1. Skin pressure
2. Skin shearing and friction
3. Immobility
4. Malnutrition
5. Incontinence
6. Decreased sensory perception

C. Assessment and staging (Box 42-3)

D. Interventions

Avoid direct massage to a reddened skin area, because massage can damage the capillary beds and cause tissue necrosis.

1. Identify clients at risk for developing a pressure injury.
2. Institute measures to prevent pressure injury, such as appropriate positioning, using pressure relief devices, ensuring adequate nutrition, and developing a plan for skin cleansing and care.
3. Perform frequent skin assessments and monitor for an alteration in skin integrity (refer to Chapter 12 for more information on skin assessment).
4. Keep the client’s skin dry and the sheets wrinkle-free; if the client is incontinent, check the client frequently and change pads or any items placed under the client immediately after they are soiled.

5. Use creams and lotions to lubricate the skin and a barrier protection ointment for the incontinent client.

6. Turn and reposition the immobile client every 2 hours or more frequently if necessary; provide active and passive range-of-motion exercises at least every 8 hours.

7. If a pressure injury is present, record the location and size of the wound (length, width, depth in centimeters), monitor and record the type and amount of exudates (a culture of the exudate may be prescribed), and assess for undermining and tunneling. Depending on agency policy, it may be required to have picture documentation on file of a pressure injury or other disruption in skin integrity that may include a client identifier, measuring device, and a label indicating wound laterality and location. If a wound or other skin problem is noted, it may be necessary to request a referral to a wound care and/or nutrition specialist.

8. Serosanguineous exudate (blood-tinged amber fluid) may be noted; purulent exudates indicate colonization of the wound with bacteria.

9. Use agency protocols for skin assessment and management of a wound.

10. Treatment may include wound dressings and debridement; skin grafting may be necessary (Tables 42-1 and 42-2).

11. Other treatments may include electrical stimulation to the wound area (increases blood vessel growth and stimulates granulation), vacuum-assisted wound closure (removes infectious material from the wound and promotes granulation), hyperbaric oxygen therapy (administration of oxygen under high pressure raises tissue oxygen concentration), and the use of topical growth factors (biologically active substances that stimulate cell growth).

---

Box 42-1

Types of Exudate from Wounds

**Serous**
Serosanguineous

- Pink colored due to the presence of a small amount of blood cells mixed with serous drainage
- Occurs as a normal part of the healing process

Sanguineous

- Red drainage from trauma to a blood vessel
- May occur with wound cleansing or other trauma to the wound bed
- Sanguineous drainage is abnormal in wounds

Hemorrhaging

- Frank blood from a leaking blood vessel
- May require emergency treatment to control bleeding
- Hemorrhage is an abnormal wound exudate

Purulent

- Yellow, gray, or green drainage due to infection in the wound

Box 42-2
Appearance of Skin Cancer Lesions

Basal Cell Carcinoma
Waxy nodule with pearly borders
Papule, red, central crater
Metastasis is rare

Squamous Cell Carcinoma
Oozing, bleeding, crusting lesion
Potentially metastatic
Larger tumors associated with a higher risk for metastasis

Melanoma
Irregular, circular, bordered lesion with hues of tan, black, or blue
Rapid infiltration into tissue, highly metastatic

Table 42-2

Types of Dressing Materials

<table>
<thead>
<tr>
<th>Type</th>
<th>Indications, Uses, and Considerations</th>
<th>Frequency of Dressing Changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alginate</td>
<td>Provides hemostasis, debridement, absorption, and protection. Can be used as packing for deep wounds and for infected wounds Requires a secondary dressing for securing</td>
<td>When dressing is saturated (every 3 to 5 days) or more frequently</td>
</tr>
<tr>
<td>Biological</td>
<td>Provides protection and debridement after eschar removal. May be used for dormant and nonhealing wounds that do not respond to other topical therapies May be used for burns or before pigskin and cadaver skin grafts Conforms to uneven wound surfaces; reduces pain Requires a secondary dressing for securing</td>
<td>Topical growth factors: changed daily Skin substitutes: the need for dressing change varies</td>
</tr>
<tr>
<td>Cotton gauze</td>
<td>Continuous dry dressing provides absorption and protection. Continuous wet dressing provides protection, a means for the delivery of topical treatment, and debridement Wet to damp dressing provides atraumatic mechanical debridement May be painful on removal</td>
<td>Clean base: every 12 to 24 hr Necrotic base: every 4 to 6 hr</td>
</tr>
<tr>
<td>Foam</td>
<td>Provides absorption, protection, insulation, and debridement Conforms to uneven wound surfaces</td>
<td>When dressing is saturated or more frequently; can remain for a maximum of 7 days</td>
</tr>

Practice Questions

423. The nurse is conducting a session about the principles of first aid and is discussing the interventions for a snakebite to an extremity. The nurse should inform those attending the session that the **first-priority** intervention in the event of this occurrence is which action?

1. Immobilize the affected extremity.
2. Remove jewelry and constricting clothing from the victim.
3. Place the extremity in a position so that it is below the level of the heart.
4. Move the victim to a safe area away from the snake and encourage the victim to rest.

424. A client calls the emergency department and tells the nurse that he came directly into contact with poison ivy shrubs. The client tells the nurse that he cannot see anything on the skin and asks the nurse what to do. The nurse should make which response?

1. “Come to the emergency department.”
2. “Apply calamine lotion immediately to the exposed skin areas.”
3. “Take a shower immediately, lathering and rinsing several times.”
4. “It is not necessary to do anything if you cannot see anything on your skin.”

425. A client is being admitted to the hospital for treatment of acute cellulitis of the lower left leg. During the admission assessment, the nurse expects to note which finding?

1. An inflammation of the epidermis only
2. A skin infection of the dermis and underlying hypodermis
3. An acute superficial infection of the dermis and lymphatics
4. An epidermal and lymphatic infection caused by *Staphylococcus*

426. The clinic nurse assesses the skin of a client with psoriasis after the client has used a new topical treatment for 2 months. The nurse identifies which
characteristics as improvement in the manifestations of psoriasis? Select all that apply.

1. Presence of striae
2. Palpable radial pulses
3. Absence of any ecchymosis on the extremities
4. Thinner and decrease in number of reddish papules
5. Scarce amount of silvery-white scaly patches on the arms

427. The clinic nurse notes that the health care provider has documented a diagnosis of herpes zoster (shingles) in the client’s chart. Based on an understanding of the cause of this disorder, the nurse determines that this definitive diagnosis was made by which diagnostic test?

1. Positive patch test
2. Positive culture results
3. Abnormal biopsy results
4. Wood’s light examination indicative of infection

428. A client returns to the clinic for follow-up treatment after a skin biopsy of a suspicious lesion performed 1 week ago. The biopsy report indicates that the lesion is a melanoma. The nurse understands that melanoma has which characteristics? Select all that apply.

1. Lesion is painful to touch.
2. Lesion is highly metastatic.
3. Lesion is a nevus that has changes in color.
4. Skin under the lesion is reddened and warm to touch.
5. Lesion occurs in body areas exposed to outdoor sunlight

429. When assessing a lesion diagnosed as basal cell carcinoma, the nurse most likely expects to note which findings? Select all that apply.

1. An irregularly shaped lesion
2. A small papule with a dry, rough scale
3. A firm, nodular lesion topped with crust
4. A pearly papule with a central crater and a waxy border
5. Location in the bald spot atop the head that is exposed to outdoor sunlight

430. A client arriving at the emergency department has experienced frostbite to the right hand. Which finding would the nurse note on assessment of the client’s hand?

1. A pink, edematous hand
2. Fiery red skin with edema in the nailbeds
3. Black fingertips surrounded by an erythematous rash
4. A white color to the skin, which is insensitive to touch

431. The staff nurse reviews the nursing documentation in a client’s chart and notes that the wound care nurse has documented that the client has a stage II pressure injury in the sacral area. Which finding would the nurse expect to note on assessment of the client’s sacral area?

1. Intact skin
2. Full-thickness skin loss
3. Exposed bone, tendon, or muscle
4. Partial-thickness skin loss of the dermis

432. The nurse manager is planning the clinical assignments for the day. Which
staff members cannot be assigned to care for a client with herpes zoster?
Select all that apply.

1. The nurse who never had roseola
2. The nurse who never had mumps
3. The nurse who never had chickenpox
4. The nurse who never had German measles
5. The nurse who never received the varicella-zoster vaccine

Answers

423. Answer: 4

Rationale: In the event of a snakebite, the first priority is to move the victim to a safe area away from the snake and encourage the victim to rest to decrease venom circulation. Next, jewelry and constricting clothing are removed before swelling occurs. Immobilizing the extremity and maintaining the extremity below heart level would be done next; these actions limit the spread of the venom. The victim is kept warm and calm. Stimulants such as alcohol or caffeinated beverages are not given to the victim because these products may speed the absorption of the venom. The victim should be transported to an emergency facility as soon as possible.

Test-Taking Strategy: Note the strategic words, first priority. Eliminate options 1 and 3 first because they are comparable or alike and relate to positioning of the affected extremity. For the remaining options, think about them and visualize each. Moving the victim to a safe area is the priority to prevent further injury from the snake.

Level of Cognitive Ability: Applying
Client Needs: Safe and Effective Care Environment
Integrated Process: Teaching and Learning
Content Area: Leadership/Management: Prioritizing
Health Problem: Adult Health: Integumentary: Bites and Stings
Priority Concepts: Clinical Judgment; Tissue Integrity

424. Answer: 3

Rationale: When an individual comes in contact with a poison ivy plant, the sap from the plant forms an invisible film on the human skin. The client should be instructed to cleanse the area by showering immediately and to lather the skin several times and rinse each time in running water. Removing the poison ivy sap will decrease the likelihood of irritation. Calamine lotion may be one product recommended for use if dermatitis develops. The client does not need to be seen in the emergency department at this time.

Test-Taking Strategy: Focus on the subject, contact with poison ivy. Recalling that dermatitis can develop from contact with an allergen and that contact with poison ivy results in an invisible film will assist in directing you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity  
Integrated Process: Nursing Process—Implementation  
Content Area: Adult Health: Integumentary  
Health Problem: Adult Health: Integumentary: Inflammations/Infections  
Priority Concepts: Client Education; Tissue Integrity  

425. Answer: 2

Rationale: Cellulitis is an infection of the dermis and underlying hypodermis that results in a deep red erythema without sharp borders and spreads widely throughout tissue spaces. The skin is erythematous, edematous, tender, and sometimes nodular. Erysipelas is an acute, superficial, rapidly spreading inflammation of the dermis and lymphatics. The infection is not superficial and extends deeper than the epidermis.

Test-Taking Strategy: Eliminate options 3 and 4 because they are comparable or alike and address the lymphatics. Eliminate option 1 because of the closed-ended word “only.”

Level of Cognitive Ability: Applying  
Client Needs: Physiological Integrity  
Integrated Process: Nursing Process—Assessment  
Content Area: Adult Health: Integumentary  
Health Problem: Adult Health: Integumentary: Inflammations/Infections  
Priority Concepts: Client Education; Tissue Integrity  

426. Answer: 4, 5

Rationale: Psoriasis skin lesions include thick reddened papules or plaques covered by silvery-white patches. A decrease in the severity of these skin lesions is noted as an improvement. The presence of striae (stretch marks), palpable pulses, or lack of ecchymosis is not related to psoriasis.

Test-Taking Strategy: Focus on the subject, manifestations of psoriasis. Use knowledge regarding the pathophysiology and signs and symptoms associated with psoriasis. This will direct you to the correct options detailing a decrease in the psoriatic signs.

Level of Cognitive Ability: Evaluating  
Client Needs: Physiological Integrity  
Integrated Process: Nursing Process—Evaluation  
Content Area: Adult Health: Integumentary  
Health Problem: Adult Health: Integumentary: Inflammations/Infections  
Priority Concepts: Clinical Judgment; Tissue Integrity  

427. Answer: 2

Rationale: With the classic presentation of herpes zoster, the clinical examination
is diagnostic. However, a viral culture of the lesion provides the definitive diagnosis. Herpes zoster (shingles) is caused by a reactivation of the varicella zoster virus, the virus that causes chickenpox. A patch test is a skin test that involves the administration of an allergen to the surface of the skin to identify specific allergies. A biopsy would provide a cytological examination of tissue. In a Wood’s light examination, the skin is viewed under ultraviolet light to identify superficial infections of the skin.

**Test-Taking Strategy:** Focus on the subject, diagnosing herpes zoster. Recalling that herpes zoster is caused by a virus will assist in directing you to the correct option. Also remember that a biopsy will determine tissue type, whereas a culture will identify an organism.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Integumentary

**Health Problem:** Adult Health: Integumentary: Inflammations/Infections

**Priority Concepts:** Clinical Judgment; Tissue Integrity

428. **Answer:** 2, 3

**Rationale:** Melanomas are pigmented malignant lesions originating in the melanin-producing cells of the epidermis. Melanomas cause changes in a nevus (mole), including color and borders. This skin cancer is highly metastatic, and a person’s survival depends on early diagnosis and treatment. Melanomas are not painful or accompanied by sign of inflammation. Although sun exposure increases the risk of melanoma, lesions may occur any place on the body, especially where birthmarks or new moles are apparent.

**Test-Taking Strategy:** Focus on the subject, characteristics of melanoma skin cancer. It is necessary to know the normal characteristics associated with melanoma to answer this question correctly. Also, recalling that melanomas are highly metastatic will assist in directing you to the correct options.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Integumentary

**Health Problem:** Adult Health: Cancer: Skin

**Priority Concepts:** Cellular Regulation; Tissue Integrity

429. **Answer:** 4, 5

**Rationale:** Basal cell carcinoma appears as a pearly papule with a central crater and rolled waxy border. Exposure to ultraviolet sunlight is a major risk factor. A melanoma is an irregularly shaped pigmented papule or plaque with a red-, white-, or blue-toned color. Actinic keratosis, a premalignant lesion, appears as a small macule or papule with a dry, rough, adherent yellow or brown scale. Squamous cell
carcinoma is a firm, nodular lesion topped with a crust or a central area of ulceration.

**Test-Taking Strategy:** Note the **strategic words**, most likely. Recall characteristics and etiology of basal cell cancer to direct you to the correct options.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Integumentary

**Health Problem:** Adult Health: Cancer: Skin

**Priority Concepts:** Cellular Regulation; Tissue Integrity

430. **Answer:** 4

**Rationale:** Assessment findings in frostbite include a white or blue color; the skin will be hard, cold, and insensitive to touch. As thawing occurs, flushing of the skin, the development of blisters or blebs, or tissue edema appears. Options 1, 2, and 3 are incorrect.

**Test-Taking Strategy:** Focus on the **subject**, assessment findings in frostbite. Noting the words *insensitive to touch* in the correct option should direct you to this option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Integumentary

**Health Problem:** Adult Health: Integumentary: Inflammations/Infections

**Priority Concepts:** Clinical Judgment; Tissue Integrity

431. **Answer:** 4

**Rationale:** In a stage II pressure injury, the skin is not intact. Partial-thickness skin loss of the dermis has occurred. It presents as a shallow open ulceration with a red-pink wound bed, without slough. It may also present as an intact or open/ruptured serum-filled blister. The skin is intact in stage I. Full-thickness skin loss occurs in stage III. Exposed bone, tendon, or muscle is present in stage IV.

**Test-Taking Strategy:** Focus on the **subject**, assessment of a pressure injury. Focusing on the words *stage II* and visualizing the appearance of a stage II pressure injury will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Integumentary

**Health Problem:** Adult Health: Integumentary: Inflammations/Infections

**Priority Concepts:** Clinical Judgment; Tissue Integrity

**Reference:** Lewis et al. (2017), pp. 172-173.
432. **Answer:** 3, 5

**Rationale:** The nurses who have not had chickenpox or did not receive the varicella zoster vaccine are susceptible to the herpes zoster virus and should not be assigned to care for the client with herpes zoster. Nurses who have not contracted roseola, mumps, or rubella are not necessarily susceptible to herpes zoster. Herpes zoster (shingles) is caused by a reactivation of the varicella zoster virus, the causative virus of chickenpox. Individuals who have not been exposed to the varicella zoster virus or who did not receive the varicella zoster vaccine are susceptible to chickenpox. Health care workers who are unsure of their immune status should have varicella titers done before exposure to a person with herpes zoster.

**Test-Taking Strategy:** Focus on the **subject**, transmission of herpes zoster. Recalling that herpes zoster is caused by a reactivation of the varicella zoster virus, the causative virus of chickenpox, will direct you to the correct options.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Safe and Effective Care Environment  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Leadership/Management: Delegating  
**Health Problem:** Adult Health: Integumentary: Inflammations/Infections  
**Priority Concepts:** Infection; Safety  
CHAPTER 43

Integumentary Medications

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts

Clinical Judgment; Safety

I. Poison Ivy Treatment (Box 43-1)
   A. Treatment of lesions includes calamine lotion and commercial products that soothe lesions, compresses and solutions that are astringent and antiseptic, and/or colloidal oatmeal baths to relieve discomfort.
   B. Topical corticosteroids are effective to prevent or relieve inflammation, especially when used before blisters form.
   C. Oral corticosteroids may be prescribed for severe reactions, and an antihistamine such as diphenhydramine may be prescribed.

II. Medications to Treat Dermatitis (Box 43-2)
   A. Description
      1. Superficial inflammatory process involving primarily the epidermis; there are many types, some of which include atopic dermatitis, contact dermatitis, and stasis dermatitis.
      2. May be treated with moisturizer and topical glucocorticoids (preferred treatment); systemic immunosuppressants may need to be prescribed if topical treatment is ineffective.
   B. Topical immunosuppressants
      1. Tacrolimus and pimecrolimus creams
      2. Side and adverse effects include redness, burning, and itching; causes sensitization of the skin to sunlight. Treated areas should be protected from direct sunlight.
      3. Tacrolimus may increase the risk of contracting varicella zoster infection in children.
      4. Tacrolimus may increase the risk of developing skin cancer and lymphoma.

When administering any topical medication or topical patches, the nurse and family caregivers should always wear gloves to protect...
self from absorption of the medication. Caregivers should also be taught to wash hands thoroughly before and after administration.

III. Topical Glucocorticoids

A. Description
1. Antiinflammatory, antipruritic, and vasoconstrictive actions
2. Preparations vary in potency and depend on the concentration and type of preparation and method of application (occlusive dressings enhance absorption, increasing the effects).
3. Systemic effects are more likely to occur with prolonged therapy and when extensive skin surfaces are treated.

B. Contraindications
1. Clients demonstrating previous sensitivity to corticosteroids
2. Clients with current systemic fungal, viral, or bacterial infections
3. Clients with current complications related to glucocorticoid therapy

C. Local side and adverse effects
1. Burning, dryness, irritation, itching
2. Thinning of the skin, striae, purpura, telangiectasia (causes thread-like red lines on the skin)
3. Skin atrophy
4. Acneiform eruptions
5. Hypopigmentation
6. Overgrowth of bacteria, fungi, and viruses

D. Systemic adverse effects
1. Growth retardation in children
2. Adrenal suppression
3. Cushing’s syndrome
4. Ocular effects (glaucoma and cataracts)

E. Interventions
1. Wear gloves; wash the area just before application to ensure cleanliness and to increase medication penetration.
2. Apply sparingly in a thin film, rubbing gently.
3. Avoid the use of a dry occlusive dressing unless specifically prescribed by the primary health care provider (PHCP).
4. Instruct the client to report signs of adverse effects to the PHCP.
5. Monitoring plasma cortisol levels may be prescribed if prolonged therapy is necessary.

In the adult, intact skin is generally impermeable to most topical medications. However, medications should not be applied to open areas unless prescribed, because undesired absorption and adverse effects can occur.

IV. Medications to Treat Actinic Keratosis (Box 43-3)

A. Description
1. Actinic keratoses are caused by prolonged exposure to the sun and appear as rough, scaly, red or brown lesions usually found on the face, scalp, arms, and back of the hands.
2. Lesions can progress to squamous cell carcinoma.
3. Treatment includes medications and therapies such as excision, cryotherapy, curettage, and laser therapy.

B. Medications (see Box 43-3)
1. Diclofenac sodium
   a. A nonsteroidal antiinflammatory topical medication; it may take up to 3 months to be effective.
   b. Side and adverse effects include dry skin, itching, redness, and rash.
2. Fluorouracil
   a. A topical medication that affects DNA and RNA synthesis and causes a sequence of responses that results in healing; results are usually seen in 2 to 6 weeks but may take 1 to 2 months longer for complete healing.
   b. Side and adverse effects include itching, burning, inflammation, rash, and increased sensitivity to sunlight.
3. Imiquimod 5% cream
   a. In addition to treating actinic keratoses, this topical medication has been used to treat venereal warts; it may take up to 4 months to be effective.
   b. Side and adverse effects include redness, skin swelling, itching, burning, sores, blisters, scabbing, and crusting of the skin.
4. Ingenol mebutate
   a. Indicated for the topical treatment of actinic keratosis; application
recommendations need to be followed closely because of the risks of allergic reaction and development of herpes zoster.
b. Side and adverse effects include skin reactions, erythema, flaking/scaling, crusting, swelling, postulation, and erosion/ulceration; allergic reactions; herpes zoster.

V. Sunscreens

A. Ultraviolet (UV) light can damage the skin and cause premalignant actinic keratoses and some types of skin cancer.
B. Sunscreens prevent the penetration of UV light and protect the skin.
C. Organic (chemical) sunscreens absorb UV light; inorganic (physical) sunscreens reflect and scatter UV light.
D. A sunscreen that protects against both UVB and UVA rays and one that has a sun protection factor (SPF) of at least 15 should be used.
E. Sunscreens are most effective when applied at least 30 minutes before exposure to the sun (sunscreens containing para-aminobenzoic acid or padimate O require application 2 hours before sun exposure).
F. Sunscreen should be reapplied every 2 to 3 hours and after swimming or sweating; otherwise, the duration of protection is reduced.
G. Products containing para-aminobenzoic acid need to be avoided by individuals allergic to benzocaine, sulfonamides, or thiazides.
H. Sunscreens can cause contact dermatitis and photosensitivity reactions.

The client should be informed that UV light is greatest between the hours of 10:00 a.m. and 4:00 p.m. and that sunglasses, protective clothing, and a hat should be worn to reduce the risk of skin damage from the sun.

VI. Medications to Treat Psoriasis (Box 43-4)

A. Description
   1. Psoriasis is a chronic inflammatory disorder that has varying degrees of severity.
   2. Treatment is based on the severity of symptoms and aims to suppress the proliferation of keratinocytes or suppress the activity of inflammatory cells.
B. Topical medications
   1. Glucocorticoids
      a. Used for mild psoriasis
      b. Should not be applied to the face, groin,
axilla, or genitalia, because the medication is readily absorbable, making the skin vulnerable to glucocorticoid-induced atrophy.

2. Tazarotene
   a. Is a vitamin A derivative
   b. Local reactions include itching, burning, stinging, dry skin, and redness; other, less common effects include rash, desquamation, contact dermatitis, inflammation, fissuring, and bleeding.
   c. Sensitization to sunlight can occur, and the client should be instructed to use sunscreen and wear protective clothing.
   d. Medication is usually applied once daily in the evening to dry skin.

3. Calcipotriene
   a. Is an analog of vitamin D
   b. May take up to 1 to 3 weeks to produce a desired effect
   c. Can cause local irritation; high-dose applications rarely have caused hypercalcemia.

4. Coal tar
   a. Suppresses DNA synthesis, miotic activity, and cell proliferation
   b. Has an unpleasant odor and may cause irritation, burning, and stinging; can also stain the skin and hair and increase sensitivity to sun
   c. May increase risk for cancer development in high doses

5. Keratolytics
   a. Soften scales and loosen the horny layer of the skin, resulting in minimal peeling to extensive desquamation
   b. Salicylic acid: Can be absorbed systemically and can cause salicylism, which is characterized by dizziness and tinnitus, hyperpnea, and psychological disturbances; salicylic acid is not applied to large surface areas or open wounds because of the risk of systemic effects.
   c. Sulfur: Promotes peeling and drying
C. Systemic medications

1. Methotrexate

   a. Reduces proliferation of epidermal cells
   b. Can be toxic; causes gastrointestinal effects such as diarrhea and ulcerative stomatitis and bone marrow depression leading to blood dyscrasias
   c. Can be hepatotoxic; hepatic function should be monitored during therapy
   d. This medication is teratogenic; women of child-bearing age should wait 3 months after discontinuation of the medication before becoming pregnant.

2. Acitretin

   a. Inhibits keratinization, proliferation, and differentiation of cells; has antiinflammatory and immunomodulator actions; used for severe psoriasis and reserved for use in those who have not responded to safer medications
   b. Is embryotoxic and teratogenic:
      Medication is contraindicated during pregnancy; pregnancy must be ruled out, and 2 reliable forms of contraception need to be implemented before the medication is started (contraception must be implemented at least 1 month before treatment starts and be continued for at least 3 years after treatment is discontinued).
   c. If pregnancy occurs during treatment with the medication, the medication is discontinued immediately and possible termination of the pregnancy is discussed.
   d. Dermatological effects include hair loss, skin peeling, dry skin, rash, pruritus, and nail disorders; other effects include rhinitis from mucous membrane irritation, inflammation of the lips, dry mouth, dry eyes, nosebleed, gingivitis, stomatitis, bone and joint pain, and spinal disorders.
   e. Can be hepatotoxic; can elevate
triglyceride levels and reduce levels of high-density lipoprotein cholesterol
f. Should not be taken with alcohol, vitamin A supplementation, or tetracycline

3. Cyclosporine
   a. An immunosuppressant that inhibits proliferation of B and T cells
   b. Can be toxic and cause kidney damage
   c. Used for severe psoriasis and reserved for use in those who have not responded to safer medications

D. Systemic biological medications (clients should be tested for tuberculosis or other infections before initiation of medications)
   1. These are injected into the skin or bloodstream; they block the altered immune system that is contributing to the psoriasis.
   2. Some are tumor necrosis factor alpha-blockers, some bind to inflammation, causing proteins/interleukins; some are a human antibody that works against interleukins
   3. Adverse effects, which are generally not severe, include upper respiratory infections, abdominal pain, headache, rash, injection site reactions, and urinary tract infections; may promote serious infections, including bacterial sepsis, invasive fungal infections, tuberculosis, and reactivation of hepatitis B; some medications increase the risk of developing lymphoma
   4. Contraindicated for persons with history of certain cancers, severe or recurrent infections, heart failure, or demyelinating neurological diseases; given with caution to persons with numbness or tingling
   5. The client should not receive any live virus vaccines, because the viruses used in some types of vaccines can cause infection in those with a weakened immune system; in addition, the PHCP needs to be informed if anyone in the household needs a vaccine.
   6. The client should not receive the bacillus Calmette-Guérin (BCG) vaccine during the 1 year before taking or 1 year after taking the medication.
   7. The client should inform the PHCP if he or she is receiving phototherapy, has any other medical condition, is pregnant or plans to become pregnant, or is breast-feeding or plans to breast-feed; safety with pregnancy has not been established with many of these medications.

E. Phototherapy
1. Coal tar and ultraviolet B (UVB) irradiation: Treatment that involves the application of coal tar for 8 to 10 hours; coal tar is washed off and the area is exposed to short-wave UV radiation (UVB).

2. Photochemotherapy (psoralen and ultraviolet A [UVA] therapy)
   a. Combines the use of long-wave radiation (UVA) with oral methoxsalen (used in very specific cases; photosensitive medication)
   b. Can cause pruritus, nausea, erythema; may accelerate the aging process of the skin; may increase the risk of skin cancer.

VII. Acne Products (Box 43-5; Fig. 43-1)

A. Description
   1. Acne lesions that are mild may be treated with nonpharmacological measures such as gentle cleansing 2 or 3 times daily (oil-based moisturizing products need to be avoided), dermabrasion, or comedo extraction.
   2. Mild acne is usually treated pharmacologically with topical agents (antimicrobials and retinoids).
   3. Moderate acne is usually treated with oral antibiotics and comedolytics.
   4. Severe acne is usually treated with isotretinoin.
   5. Hormonal medications may be prescribed to treat acne in female clients.
   6. A type of combination therapy may be prescribed to treat acne.
   7. Actions of the medications may include suppressing the growth of Propionibacterium acnes, reducing inflammation, promoting keratolysis, unplugging existing comedones and preventing their development, and normalizing hyperproliferation of epithelial cells within the hair follicles; some medications cause thinning of the skin, which facilitates penetration of other medications.
   8. For topical applications: Site should be washed and allowed to dry completely before application; hands should be washed after application.
   9. All topical products are kept away from the eyes, inside the nose, lips, mucous membranes, hair, and inflamed or denuded skin.

B. Topical antibiotic products
   1. Benzoyl peroxide
      a. Can produce drying and peeling
b. Severe local irritation (burning, blistering, scaling, swelling) may require reducing the frequency of applications.
c. Some products may contain sulfites; monitor for serious allergic reactions.

2. Salicylic acid and sulfur/sulfacetamide can be used as well.

3. Clindamycin and erythromycin
   a. Both products are antibiotics that suppress the growth of *P. acnes*.
   b. Combination therapy with benzoyl peroxide prevents the emergence of resistant bacteria; fixed-dose combinations include clindamycin/benzoyl peroxide and erythromycin/benzoyl peroxide.

4. Dapsone: Side and adverse effects include oiliness, peeling, dryness, and erythema of the skin (oral form of medication is used to treat leprosy).

C. Topical retinoids
   1. Tretinoin
      a. A derivative of vitamin A (vitamin A supplements should be discontinued during therapy)
      b. In addition to treating acne, it may be prescribed to reduce fine wrinkles, skin roughness, and mottled hyperpigmentation, as with age spots.
      c. Can cause localized side and adverse effects such as blistering, peeling, crusting, burning, and swelling of the skin.
      d. Abrasive products and keratolytic products are discontinued before using tretinoin to decrease localized adverse effects.
      e. Instruct the client to apply a sunscreen with an SPF of 15 or greater and to wear protective clothing when outdoors due to sensitivity to UV light.

2. Adapalene: Similar to tretinoin and sensitizes the skin to UV light; adverse effects include burning and itching after application, redness, dryness, and scaling of the skin. Initially may worsen acne; benefits seen in 8 to 12 weeks.

3. Tazarotene
   a. Is a derivative of vitamin A (vitamin A
supplements should be discontinued during therapy)

b. In addition to acne, it is used to treat wrinkles and psoriasis.
c. Can cause itching, burning, and dry skin and sensitizes the skin to UV light

4. Azelaic acid can cause burning, itching, stinging, and redness of the skin; it can also cause hypopigmentation of the skin in clients with a dark complexion.

D. Oral antibiotics

1. Includes doxycycline, minocycline, tetracycline, erythromycin, trimethoprim-sulfamethoxazole, cephalosporins, penicillins
2. Improvement develops slowly with the use of oral antibiotics and may take 3 to 6 months for some improvement to be noted; after control of symptoms, the client is usually switched to a topical antibiotic.

E. Isotretinoin

1. Derivative of vitamin A (vitamin A supplements should be discontinued during therapy); in addition, the use of tetracyclines can increase the risk of adverse effects and should be discontinued before use of isotretinoin.
2. Used to treat severe cystic acne; reserved for persons who have not responded to other therapies, including systemic antibiotics
3. Side and adverse effects include nosebleeds; inflammation of the lips or eyes; dryness or itching of the skin, nose, or mouth; pain, tenderness, or stiffness in the joints, bones, or muscles; and back pain.
4. Less common side and adverse effects include rash, hair loss, peeling of the skin, headache, and reduction in night vision.
5. Causes sensitization of the skin to UV light
6. The medication elevates triglyceride levels, which should be measured before and during therapy; alcohol consumption should be eliminated during therapy because alcohol could potentiate elevation of serum triglyceride levels.
7. The medication may cause depression in some clients; if depression occurs, the medication should be discontinued.

Isotretinoin is highly teratogenic and can cause fetal
abnormalities. If prescribed, the client needs to follow strict rules of the iPLEDGE program. It must not be used if the client is pregnant.

F. iPLEDGE program

1. A risk management program that ensures that no woman starting isotretinoin is pregnant and that no woman taking this medication becomes pregnant; refer to American Academy of Dermatology Association at [https://www.aad.org/public/diseases/acne-and-rosacea/isotretinoin-treatment-for-severe-acne](https://www.aad.org/public/diseases/acne-and-rosacea/isotretinoin-treatment-for-severe-acne)
2. Access to the medication is controlled through a central automated system.
3. Strict rules must be followed by the client, PHCP prescribing the medication, pharmacist dispensing the medication, and wholesaler of the medication to ensure safety and to ensure that no woman is pregnant on initiation of therapy or becomes pregnant while taking the medication.
4. Also see iPledge® program at [https://www.ipledgeprogram.com/iPledgeUI/home.u](https://www.ipledgeprogram.com/iPledgeUI/home.u)

G. Hormonal medications

1. Hormonal medications such as oral contraceptives and spironolactone may be prescribed to treat acne in female clients.
2. These medications decrease androgen activity, resulting in decreased production of sebum.
3. Spironolactone is teratogenic; therefore, contraception during its use is necessary.
4. Side and adverse effects of spironolactone include breast tenderness, menstrual irregularities, and hyperkalemia.

VIII. Burn Products: (Box 43-6) Refer to Chapter 69 for information on Caring for the Burn Client

A. Silver sulfadiazine

1. Has broad spectrum of activity against gram-negative bacteria, gram-positive bacteria, and yeast
2. Silver is released slowly from the cream, which is selectively toxic to bacteria.
3. Used primarily to prevent sepsis in clients with burns
4. Not a carbonic anhydrase inhibitor; does not cause acidosis
5. Apply 1/16-inch film (keep burn covered at all times with silver sulfadiazine).
6. Side and adverse effects include rash and itching, blue-green or gray skin discoloration, leukopenia, and interstitial nephritis.
7. Monitor complete blood cell count, particularly the
white blood cells, frequently; if leukopenia develops, the PHCP is notified (medication is usually discontinued).

B. Mafenide acetate
1. Water-soluble cream that is bacteriostatic for gram-negative and gram-positive organisms
2. Used to treat burns to reduce the bacteria present in avascular tissues
3. Diffuses through the devascularized areas of the skin and may precipitate metabolic acidosis with the client displaying hyperventilation; monitor blood gases and electrolytes.
4. Apply 1/16-inch (1.5 mm) film directly to the burn.
5. Side effects can include local pain and rash; medicate for pain before application.
6. Adverse effects include bone marrow depression, hemolytic anemia, and metabolic acidosis.
7. Keep the burn covered with mafenide acetate at all times.
8. Notify the PHCP if hyperventilation occurs; if acidosis develops, mafenide acetate is washed off the skin and usually discontinued for 1 to 2 days.

**Box 43-1**

**Poison Ivy Treatment Products**

- Bentoquatam—for preventive use
- Calamine lotion
- Hydrocortisone
- Zinc acetate; isopropanol
- Zinc acetate; isopropanol; benzyl alcohol

**Box 43-2**

**Medications to Treat Dermatitis**

**Systemic Immunosuppressants**

- Azathioprine
- Cyclosporine
- Methotrexate
- Oral glucocorticoids
Topical Immunosuppressants

- Pimecrolimus 1% cream
- Tacrolimus

**Box 43-3**

**Medications to Treat Actinic Keratosis**

- Diclofenac sodium 3% gel
- Fluorouracil
- Imiquimod 5% cream
- Ingenol mebutate

**Box 43-4**

**Medications and Treatments for Psoriasis**

**Topical Medications**

- Calcipotriene
- Coal tar
- Glucocorticoids
- Keratolytics (topical salicylic acid; sulfur)
- Tazarotene

**Systemic Medications**

- Acitretin
- Cyclosporine
- Methotrexate

**Systemic Biological Medications**

- Adalimumab
- Brodalumab
- Etanercept
- Gusekumab
- Infliximab
- Ixekizumab
- Ustekinumab
- Secukinumab

**Phototherapy**

- Coal tar and ultraviolet B irradiation
- Photochemotherapy (psoralen and ultraviolet A therapy)

---

**Box 43-5**

**Acne Products**

**Topical Antibiotics**

- Benzoyl peroxide
- Clindamycin and erythromycin
- Clindamycin/tretinoin combination gel
- Dapsone
  - *Fixed dose combinations*: Clindamycin/benzoyl peroxide and erythromycin/benzoyl peroxide

**Topical Retinoids**

- Adapalene
- Azelaic acid
- Tazarotene
- Tretinoin

**Oral Medications**

- Doxycycline
- Erythromycin
- Isotretinoin
- Minocycline
- Tetracycline

**Hormonal Medications**

- Oral contraceptives
- Spironolactone
FIG. 43-1  Acne vulgaris. A, Comedones with a few inflammatory pustules. B, Papulopustular acne. (From Perry et al., 2010.)

Box 43-6

Burn Products

- Mafenide acetate
- Silver sulfadiazine
- Bacitracin topical ointment (first-degree burns only)
- Povidone-iodine

Practice Questions

433. Salicylic acid is prescribed for a client with a diagnosis of psoriasis. The nurse monitors the client, knowing that which finding indicates the presence of systemic toxicity from this medication?
   1. Tinnitus
   2. Diarrhea
   3. Constipation
   4. Decreased respirations

434. The health education nurse provides instructions to a group of clients regarding measures that will assist in preventing skin cancer. Which
instructions should the nurse provide? **Select all that apply.**
1. Sunscreen should be applied every 8 hours.
2. Use sunscreen when participating in outdoor activities.
3. Wear a hat, opaque clothing, and sunglasses when in the sun.
4. Avoid sun exposure in the late afternoon and early evening hours.
5. Examine your body monthly for any lesions that may be suspicious.

435. Silver sulfadiazine is prescribed for a client with a burn injury. Which laboratory finding requires the need for follow-up by the nurse?
1. Glucose level of 99 mg/dL (5.65 mmol/L)
2. Platelet level of 300,000 mm$^3$ (300 × 10$^9$/L)
3. Magnesium level of 1.5 mEq/L (0.75 mmol/L)
4. White blood cell count of 3000 mm$^3$ (3.0 × 10$^9$/L)

436. A burn client is receiving treatments of topical mafenide acetate to the site of injury. The nurse monitors the client, knowing that which finding indicates that a systemic effect has occurred?
1. Hyperventilation
2. Elevated blood pressure
3. Local rash at the burn site
4. Local pain at the burn site

437. Isotretinoin is prescribed for a client with severe acne. Before the administration of this medication, the nurse anticipates that which laboratory test will be prescribed?
1. Potassium level
2. Triglyceride level
3. Hemoglobin A$\text{1C}$
4. Total cholesterol level

438. A client with severe acne is seen in the clinic and the primary health care provider (PHCP) prescribes isotretinoin. The nurse reviews the client’s medication record and would contact the PHCP if the client is also taking which medication?
1. Digoxin
2. Phenytoin
3. Vitamin A
4. Furosemide

439. The nurse is applying a topical corticosteroid to a client with eczema. The nurse understands that it is safe to apply the medication to which body areas? **Select all that apply.**
1. Back
2. Axilla
3. Eyelids
4. Soles of the feet
5. Palms of the hands

440. The clinic nurse is performing an admission assessment on a client and notes that the client is taking azelaic acid to treat acne. The nurse determines that which client complaint may be associated with use of this medication?
1. Itching
2. Euphoria
3. Drowsiness
4. Frequent urination

441. Silver sulfadiazine is prescribed for a client with a partial-thickness burn, and the nurse provides teaching about the medication. Which statement made by the client indicates a need for further teaching about the treatments?

1. “The medication is an antibacterial.”
2. “The medication will help heal the burn.”
3. “The medication should be applied directly to the wound.”
4. “The medication is likely to cause stinging every time it is applied.”

442. The camp nurse asks the children preparing to swim in the lake if they have applied sunscreen. The nurse reminds the children that chemical sunscreens are most effective when applied at which times?

1. Immediately before swimming
2. 5 minutes before exposure to the sun
3. Immediately before exposure to the sun
4. At least 30 minutes before exposure to the sun

Answers

433. Answer: 1

Rationale: Salicylic acid is absorbed readily through the skin, and systemic toxicity (salicylism) can result. Symptoms include tinnitus, dizziness, hyperpnea, and psychological disturbances. Constipation and diarrhea are not associated with salicylism.

Test-Taking Strategy: Focus on the subject, systemic toxicity. Noting the name of the medication will assist in directing you to the correct option if you can recall the toxic effects that occur with acetylsalicylic acid (aspirin).

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Pharmacology: Integumentary: Antiinflammatory/Antiinfective
Health Problem: Adult Health: Integumentary: Inflammations/Infections
Priority Concepts: Clinical Judgment; Tissue Integrity

434. Answer: 2, 3, 5

Rationale: The client should be instructed to avoid sun exposure between the hours of brightest sunlight: 10 a.m. and 4 p.m. Sunscreen, a hat, opaque clothing, and sunglasses should be worn for outdoor activities. The client should be instructed to examine the body monthly for the appearance of any cancerous or precancerous lesions. Sunscreen should be applied 30 minutes to 1 hour before sun exposure, and reapplied every 2 to 3 hours, and after swimming or sweating; otherwise, the
duration of protection is reduced.

**Test-Taking Strategy:** Focus on the **subject**, measures to prevent skin cancer. Read each option carefully. Noting the time frames in options 1 and 4 will assist in eliminating these options.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Health Promotion and Maintenance  
**Integrated Process:** Teaching and Learning  
**Content Area:** Pharmacology: Integumentary: Sunscreens  
**Health Problem:** Adult Health: Integumentary: Burns  
**Priority Concepts:** Client Education; Health Promotion  

435. **Answer:** 4  

**Rationale:** Silver sulfadiazine is used for the treatment of burn injuries. Adverse effects of this medication include rash and itching, blue-green or gray skin discoloration, leukopenia, and interstitial nephritis. The nurse should monitor a complete blood count, particularly the white blood cells, frequently for the client taking this medication. If leukopenia develops, the primary health care provider is notified and the medication is usually discontinued. The white blood cell count noted in option 4 is indicative of leukopenia. The other laboratory values are not specific to this medication and are also within normal limits.

**Test-Taking Strategy:** Note the **strategic words**, need for follow-up. Eliminate options 1, 2, and 3 because they are **comparable or alike** and are within normal limits. In addition, recall that leukopenia is an adverse effect requiring discontinuation of the medication.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Pharmacology: Integumentary: Burn Products  
**Health Problem:** Adult Health: Integumentary: Burns  
**Priority Concepts:** Clinical Judgment; Tissue Integrity  

436. **Answer:** 1  

**Rationale:** Mafenide acetate is a carbonic anhydrase inhibitor and can suppress renal excretion of acid, thereby causing acidosis. Clients receiving this treatment should be monitored for signs of an acid-base imbalance (hyperventilation). If this occurs, the medication will probably be discontinued for 1 to 2 days. Options 3 and 4 describe local rather than systemic effects. An elevated blood pressure may be expected from the pain that occurs with a burn injury.

**Test-Taking Strategy:** Note the words **systemic effect**. Options 3 and 4 can be eliminated because they are **comparable or alike** and are local rather than systemic effects. From the remaining options, recall that the client in pain would likely have an elevated blood pressure. This should direct you to the correct option.

**Level of Cognitive Ability:** Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Pharmacology: Integumentary: Burn Products
Health Problem: Adult Health: Integumentary: Burns
Priority Concepts: Gas Exchange; Tissue Integrity

437. Answer: 2

Rationale: Isotretinoin can elevate triglyceride levels. Blood triglyceride levels should be measured before treatment and periodically thereafter until the effect on the triglycerides has been evaluated. There is no indication that isotretinoin affects potassium, hemoglobin A1C, or total cholesterol levels.

Test-Taking Strategy: Note the subject, laboratory values that should be monitored specifically for the client taking isotretinoin. Recall that the medication can affect triglyceride levels in the client.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Pharmacology: Integumentary: Acne Products
Health Problem: Adult Health: Integumentary: Inflammations/Infections
Priority Concepts: Cellular Regulation; Tissue Integrity

438. Answer: 3

Rationale: Isotretinoin is a metabolite of vitamin A and can produce generalized intensification of isotretinoin toxicity. Because of the potential for increased toxicity, vitamin A supplements should be discontinued before isotretinoin therapy. There are no contraindications associated with digoxin, phenytoin, or furosemide.

Test-Taking Strategy: Focus on the subject, the need to contact the PHCP to ensure client safety. Recall that isotretinoin is a metabolite of vitamin A. Vitamin A is a fat-soluble vitamin, and therefore it is possible to develop toxic levels. This will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Safe and Effective Care Environment
Integrated Process: Nursing Process—Implementation
Content Area: Pharmacology: Integumentary: Acne Products
Health Problem: Adult Health: Integumentary: Inflammations/Infections
Priority Concepts: Collaboration; Safety

439. Answer: 1, 4, 5

Rationale: Topical corticosteroids can be absorbed into the systemic circulation. Absorption is higher from regions where the skin is especially permeable (scalp, axilla, face, eyelids, neck, perineum, genitalia), and lower from regions where
permeability is poor (back, palms, soles). The nurse should avoid areas of higher absorption to prevent systemic absorption.

**Test-Taking Strategy:** Focus on the **subject**, permeability and the potential for increased systemic absorption. Eliminate options 2 and 3, because these body areas are comparable or alike in terms of skin substance. From the remaining options, think about permeability of the skin area. This should direct you to the correct options.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Pharmacology: Integumentary: Antiinflammatory/Antiinfective

**Health Problem:** Adult Health: Integumentary: Inflammations/Infections

**Priority Concepts:** Safety; Tissue Integrity

440. **Answer:** 1

**Rationale:** Azelaic acid is a topical medication used to treat mild to moderate acne. Adverse effects include burning, itching, stinging, redness of the skin, and hypopigmentation of the skin in clients with a dark complexion. The effects noted in the other options are not specifically associated with this medication.

**Test-Taking Strategy:** Focus on the **subject**, an effect associated with the use of azelaic acid. Focusing on the name of the medication and recalling that acne medications commonly cause local irritation will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Pharmacology: Integumentary: Acne Products

**Health Problem:** Adult Health: Integumentary: Inflammations/Infections

**Priority Concepts:** Clinical Judgment; Tissue Integrity

**Reference:** Skidmore-Roth (2017), pp. 1286-1287.

441. **Answer:** 4

**Rationale:** Silver sulfadiazine is an antibacterial that has a broad spectrum of activity against gram-negative bacteria, gram-positive bacteria, and yeast. It is applied directly to the wound to assist in healing. It does not cause stinging when applied.

**Test-Taking Strategy:** Note the **strategic words**, need for further teaching. These words indicate a negative event query and ask you to select an option that is an incorrect statement. Recalling the characteristics of this medication will assist in answering correctly.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Integumentary: Burn Products

**Health Problem:** Adult Health: Integumentary: Burns
442. **Answer:** 4

**Rationale:** Sunscreens are most effective when applied at least 30 minutes before exposure to the sun so that they can penetrate the skin. All sunscreens should be reapplied after swimming or sweating.

**Test-Taking Strategy:** Knowledge that sunscreens need to penetrate the skin will assist in eliminating options 2 and 3. Next, noting the **strategic words**, *most effective*, will assist in directing you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Integumentary: Sunscreens

**Health Problem:** Adult Health: Integumentary: Burns

**Priority Concepts:** Client Education; Safety

UNIT VIII
Oncological and Hematological Problems of the Adult Client
Introduction

Pyramid to Success
Pyramid Points focus on treatment modalities related to an oncological problem, such as pain management, internal and external radiation, and chemotherapy. In preparation for the NCLEX®, focus on the following oncological problems: skin cancer; leukemia; breast cancer; testicular cancer; stomach, bowel, and pancreatic cancers; bladder cancer; prostate cancer; and lung cancer. Particular attention is given to the nursing care related to these problems and treatment modalities, client adaptation to acceptance of diagnosis and associated lifestyle changes, and the impact of the treatment for the disorder on daily life. Also, concentrate on the complications related to chemotherapy, such as hematological problems, and the nursing measures required in monitoring for these complications and preventing life-threatening conditions, such as infection and bleeding.

Client Needs: Learning Objectives

Safe and Effective Care Environment
Discussing oncology-related consultations and referrals with the interprofessional health care team
Ensuring that advance directives are in the client’s medical record
Ensuring advocacy related to the client’s decisions
Ensuring that informed consent for treatments and procedures has been obtained
Establishing priorities
Handling hazardous and infectious materials related to radiation and chemotherapy safely
Implementing protective, standard, and other precautions
Maintaining medical and surgical asepsis and preventing infection
Providing confidentiality regarding diagnosis
Upholding client rights

Health Promotion and Maintenance
Discussing expected body image changes related to chemotherapy and treatments
Providing client and family instructions regarding home care
Providing instructions regarding regular breast or testicular self-examinations
Respecting the client’s lifestyle choices
Teaching about health promotion programs regarding risks for cancer
Teaching about health screening measures for cancer

**Psychosocial Integrity**

Assessing the client’s ability to cope, adapt, and/or solve problems during illness or stressful events
Assessing the concerns of the client who survived cancer
Assisting the client and family to cope with the alteration in body image
Discussing end-of-life and grief and loss issues related to death and the dying process
Mobilizing appropriate support and resource systems
Promoting a positive environment to maintain optimal quality of life
Respecting religious, spiritual, and cultural preferences

**Physiological Integrity**

Administering blood and blood products
Caring for central venous access devices and implanted ports
Caring for the client receiving chemotherapy or radiation therapy
Managing pain
Monitoring diagnostic tests and laboratory values, such as white blood cell and platelet counts
Monitoring for expected and unexpected responses to radiation and chemotherapy
Protecting the client from the life-threatening adverse effects of treatments
Providing basic care and comfort
Providing nutrition
CHAPTER 44

Oncological and Hematological Problems

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts

Cellular Regulation; Safety

I. Cancer
   A. Description
      1. Cancer is a malignant neoplastic disorder that can involve all body organs with manifestations that vary according to the body system affected and type of tumor cells.
      2. Cells lose their normal growth-controlling mechanism, and the growth of cells is uncontrolled.
      3. Cancer produces serious health problems such as impaired immune and hematopoietic (blood-producing) function, altered gastrointestinal tract structure and function, motor and sensory deficits, and decreased respiratory function.

   B. Metastasis (Box 44-1)
      1. Cancer cells move from their original location to other sites.
      2. Routes of metastasis
         a. Local seeding: Distribution of shed cancer cells occurs in the local area of the primary tumor.
         b. Bloodborne metastasis: Tumor cells enter the blood, which is the most common cause of cancer spread.
         c. Lymphatic spread: Primary sites rich in lymphatics are more susceptible to early metastatic spread.

C. Cancer classification
   1. Solid tumors: Associated with the organs from which they develop, such as breast cancer or lung cancer
   2. Hematological cancers: Originate from blood cell–forming tissues, such as leukemias, lymphomas, and multiple myeloma
D. Grading and staging (Box 44-2)
1. Grading and staging are methods used to describe the tumor.
2. These methods describe the extent of the tumor, the extent to which malignancy has increased in size, the involvement of regional nodes, and metastatic development.
3. Grading a tumor classifies the cellular aspects of the cancer and is an indicator of tumor growth rate and spread.
4. Staging classifies the severity and clinical aspects of the cancer and degree of metastasis at diagnosis.

E. Factors that influence cancer development
1. Environmental factors
   a. Chemical carcinogen: Factors include industrial chemicals, medications, and tobacco.
   b. Physical carcinogen: Factors include ionizing radiation (diagnostic and therapeutic x-rays) and ultraviolet radiation (sun, tanning beds, and germicidal lights), chronic irritation, and tissue trauma.
   c. Viral carcinogen: Viruses capable of causing cancer are known as oncoviruses, such as Epstein-Barr virus, hepatitis B virus, and human papillomavirus.
   d. Helicobacter pylori infection is associated with an increased risk of gastric cancer.
2. Obesity and dietary factors, including preservatives, contaminants, additives, alcohol, and nitrates
3. Genetic predisposition: Factors include an inherited predisposition to specific cancers, inherited conditions associated with cancer, familial clustering, and chromosomal aberrations.
4. Age: Advancing age is a significant risk factor for the development of cancer.
5. Immune function: The incidence of cancer is higher in immunosuppressed individuals, such as those with acquired immunodeficiency syndrome and organ transplant recipients who are taking immunosuppressive medications.

F. Prevention: Avoidance of known or potential carcinogens and avoidance or modification of the factors associated with the development of cancer cells.

G. Early detection (Box 44-3)
1. Mammography
II. Diagnostic Tests

A. Diagnostic tests to be performed depend on the suspected primary or metastatic site of the cancer; invasive procedures require informed consent (Box 44-4).

B. Biopsy

1. Description
   a. Biopsy is the definitive means of diagnosing cancer and provides histological proof of malignancy.
   b. Biopsy involves the surgical incision to obtain a small piece of tissue for microscopic examination.

2. Types
   a. Needle: Aspiration of cells
   b. Incisional: Removal of a wedge of suspected tissue from a larger mass
   c. Excisional: Complete removal of the entire lesion
   d. Staging: Multiple needle or incisional biopsies in tissues where metastasis is suspected or likely (see Boxes 44-1 and 44-2)

3. Tissue examination
   a. Following excision, a frozen section or a permanent paraffin section is prepared to examine the specimen.
   b. The advantage of the frozen section is the speed with which the section can be prepared and the diagnosis made, because only minutes are required for this test.
   c. Permanent paraffin section takes about 24 hours; however, it provides clearer details than the frozen section.

4. Interventions
   a. The procedure usually is performed in an outpatient surgical setting.
   b. Prepare the client for the diagnostic procedure and provide postprocedure instructions.
c. Ensure that informed consent has been obtained.

III. Pain Control

A. Causes of pain
1. Bone destruction
2. Obstruction of an organ
3. Compression of peripheral nerves
4. Infiltration, distention of tissue
5. Inflammation, necrosis
6. Psychological factors, such as fear or anxiety; a distress screening tool may be used to assess emotional health (see http://www.cancer.org/treatment/treatmentsandsideeffectsin-people-with-cancer-tools-to-measure-distress).

B. Interventions
1. Collaborate with other members of the health care team to develop a pain management program.
2. Administer oral preparations if possible and if they provide adequate relief of pain; the transdermal or transmucosal route may also be prescribed.
3. Mild or moderate pain may be treated with salicylates, acetaminophen, and nonsteroidal anti-inflammatory drugs (NSAIDs).
4. Severe pain is treated with opioids, such as codeine sulfate, morphine sulfate, methadone, and hydromorphone hydrochloride. Neuropathic pain may be treated with a variety of anticonvulsants and antidepressants, as well as opioids.
5. Subcutaneous injections and continuous intravenous (IV) infusions of opioids provide rapid pain control; equianalgesic comparison charts should be used when switching routes of administration of opioids.
6. Monitor vital signs and for side effects of medications.
7. Monitor for effectiveness of medications and collaborate with the primary health care provider (PHCP) if medication is ineffective.
8. Provide nonpharmacological techniques of pain control such as relaxation, guided imagery, biofeedback, massage, and heat-cold application.

Assess the client’s pain; pain is what the client describes or says that it is. Do not undermedicate the client with cancer who is in pain.

IV. Surgery

A. Description: Surgery is indicated to diagnose, stage, and treat
certain types of cancer.
B. Prophylactic surgery
   1. Prophylactic surgery is performed in clients with an existing premalignant condition or a known family history or genetic mutation that strongly predisposes the person to the development of cancer.
   2. An attempt is made to remove the tissue or organ at risk and thus prevent the development of cancer.
C. Curative surgery: All gross and microscopic tumor is removed or destroyed.
D. Control (cytoreductive or “debulking”) surgery
   1. Control surgery is a debulking procedure that consists of removing a large portion of a locally invasive tumor, such as advanced ovarian cancer.
   2. Surgery decreases the number of cancer cells; therefore, it may increase the chance that other therapies will be successful.
E. Palliative surgery
   1. Palliative surgery is performed to improve quality of life during the survival time.
   2. Palliative surgery is performed to reduce pain, relieve airway obstruction, relieve obstructions in the gastrointestinal or urinary tract, relieve pressure on the brain or spinal cord, prevent hemorrhage, remove infected or ulcerated tumors, or drain abscesses.
F. Reconstructive or rehabilitative surgery is performed to improve quality of life by restoring maximal function and appearance, such as breast reconstruction after mastectomy.
G. Adverse effects of surgery
   1. Loss or loss of function of a specific body part
   2. Reduced function as a result of organ loss
   3. Scarring or disfigurement
   4. Grieving about altered body image or imposed change in lifestyle
   5. Pain, infection, bleeding, thromboembolism
V. Chemotherapy
   A. Description
      1. Chemotherapy kills or inhibits the reproduction of neoplastic cells and kills normal cells.
      2. The effects are systemic because chemotherapy is usually administered systemically.
      3. Normal cells most profoundly affected include those of the skin, hair, and lining of the gastrointestinal tract; spermatocytes; and hematopoietic cells.
      4. Usually, several chemotherapy and biotherapy agents are used in combination (combination therapy) to increase the therapeutic response.
      5. Combination chemotherapy is planned by the PHCP
so that medications with overlapping toxicities and **nadirs** (the time during which bone marrow activity and white blood cell counts are at their lowest) are not administered at or near the same time; this will minimize immunosuppression.

6. Chemotherapy may be combined with other treatments, such as surgery and radiation.

B. Common side effects include fatigue, alopecia, nausea and vomiting, mucositis, skin changes, and myelosuppression (neutropenia, anemia, and thrombocytopenia).

C. See Chapter 45 for information regarding care of the client receiving chemotherapy.

VI. Radiation Therapy

A. Description

1. Radiation therapy destroys cancer cells, with minimal exposure of normal cells to the damaging effects of radiation; the damaged cells die or become unable to divide.

2. Radiation therapy is effective on tissues directly within the path of the radiation beam.

3. Side effects include local skin changes and irritation, alopecia (hair loss), fatigue (most common side effect of radiation), and altered taste sensation; the effects vary according to the site of treatment.

4. External beam radiation (also called *teletherapy*) and internal radiation (also called *brachytherapy*) are the types of radiation therapy most commonly used to treat cancer.

B. External beam radiation (teletherapy): The actual radiation source is external to the client.

1. Instruct the client regarding self-care of the skin (Box 44-5).

2. The client does not emit radiation and does not pose a hazard to anyone else.

C. Brachytherapy

1. The radiation source comes into direct, continuous contact with tumor tissues for a specific time.

2. The radiation source is within the client; for a period of time, the client emits radiation and can pose a hazard to others.

3. Brachytherapy includes an unsealed source or a sealed source of radiation.

4. Unsealed radiation source
   a. Administration is via the oral or IV
route or by instillation into body cavities.

b. The source is not confined completely to one body area, and it enters body fluids and eventually is eliminated via various excreta, which are radioactive and harmful to others. Most of the source is eliminated from the body within 48 hours; then neither the client nor the excreta is radioactive or harmful.

5. Sealed radiation source (Priority Nursing Actions) (Box 44-6)

a. A sealed, temporary or permanent radiation source (solid implant) is implanted within the tumor target tissues.

b. The client emits radiation while the implant is in place, but the excreta are not radioactive.

6. Removal of sealed radiation sources

a. The client is not radioactive after removal.

b. Inform the client that cancer is not contagious.

c. Inform the client to follow the PHCPs prescription regarding resumption of sexual intercourse if the implant was cervical or vaginal.

d. Advise the client who had a cervical or vaginal implant to notify the PHCP if any of the following occurs: severe diarrhea, frequent urination, urethral burning for more than 24 hours, hematuria, heavy vaginal bleeding, extreme fatigue, abdominal pain, fever over 100° F (38° C), or other signs of infection.

Priority Nursing Actions

Sealed Radiation Implant that Dislodges

1. Encourage the client to lie still.
2. Use a long-handed forceps to retrieve the radioactive source.
3. Deposit the radioactive source in a lead container.
4. Contact the radiation oncologist.
VII. Hematopoietic Stem Cell Transplantation
A. Description
1. Bone marrow transplantation (BMT) and peripheral blood stem cell transplantation (PBSCT) are procedures that replace stem cells that have been destroyed by high doses of chemotherapy and/or radiation therapy.
2. BMT and PBSCT are most commonly used in the treatment of leukemia and lymphoma but are also used to treat other cancers, such as neuroblastoma and multiple myeloma.
3. The goal of treatment is to rid the client of all leukemic or other malignant cells through treatment with high doses of chemotherapy and whole-body irradiation.
4. Because these treatments are damaging to bone marrow cells, without the replacement of blood-forming stem cell function through transplantation, the client would die of infection or hemorrhage.
B. Types of donor stem cells
1. Allogeneic: Stem cell donor is usually a sibling, a parent with a similar tissue type, or a person who is not related to the client (unrelated donor).
2. Syngeneic: Stem cells are from an identical twin.
3. Autologous
   a. Autologous donation is the most common type.
   b. The client receives his or her own stem cells.
   c. Stem cells are harvested during disease remission and are stored frozen to be reinfused later.
C. Procedure
1. Harvest
   a. The stem cells used in PBSCT come from the bloodstream in a 4- to 6-hour process called apheresis or leukapheresis (the blood is removed through a central venous catheter, and an apheresis machine removes the stem cells and returns the remainder of the blood to the donor).
   b. In BMT, marrow is harvested through...
multiple aspirations from the iliac crest to retrieve sufficient bone marrow for the transplant.
c. Marrow from the client is filtered for residual cancer cells.
d. Allogeneic marrow is transfused immediately; autologous marrow is frozen for later use (cryopreservation).
e. Harvesting is done before the initiation of the conditioning regimen.

2. **Conditioning** refers to an immunosuppression therapy regimen used to eradicate all malignant cells, provide a state of immunosuppression, and create space in the bone marrow for the engraftment of the new marrow.

3. **Transplantation**
   a. Stem cells are administered through the client’s central line in a manner similar to that for a blood transfusion.
   b. Stem cells may be administered by IV infusion or by IV push directly into the central line.

4. **Engraftment**
   a. The transfused stem cells move to the marrow-forming sites of the recipient’s bones.
   b. Engraftment occurs when the white blood cell (WBC), erythrocyte, and platelet counts begin to rise.
   c. When successful, the engraftment process takes 2 to 5 weeks.

D. **Posttransplantation period:** Infection, bleeding, or neutropenia and thrombocytopenia are major concerns until engraftment occurs.

During the posttransplantation period, the client remains without any natural immunity until the donor stem cells begin to proliferate and engraftment occurs.

E. **Complications**

1. Failure to engraft: If the transplanted stem cells fail to engraft, the client will die unless another transplantation is attempted and is successful.
2. **Graft-versus-host disease in allogeneic transplants**
   a. Although the recipient cannot recognize the donated stem cells as foreign or nonself because of the total
immunosuppression, the immune-competent cells of the donor recognize the recipient’s cells as foreign and mount an immune offense against them.

b. Graft-versus-host disease is managed cautiously with immunosuppressive agents to avoid suppressing the new immune system to such an extent that the client becomes more susceptible to infection, or the transplanted cells stop engrafting.

3. Hepatic veno-occlusive disease
   a. The disease involves occlusion of the hepatic venules by thrombosis or phlebitis.
   b. Signs include right upper quadrant abdominal pain, jaundice, ascites, weight gain, and hepatomegaly.
   c. Early detection is critical because there is no known way to open the hepatic vessels.
   d. The client will be treated with fluids and supportive therapy.

VIII. Skin Cancer (see Chapter 42)

IX. Leukemia (Box 44-7)
   A. Description
   1. Leukemias are a group of hematological malignancies involving abnormal overproduction of leukocytes, usually at an immature stage, in the bone marrow.
   2. The 2 major types of leukemia are lymphocytic (involving abnormal cells from the lymphoid pathway) and myelocytic or myelogenous (involving abnormal cells from the myeloid pathways).
   3. Leukemia may be acute, with a sudden onset, or chronic, with a slow onset and persistent symptoms over a period of years.
   4. Leukemia affects the bone marrow, causing anemia, leukopenia, the production of immature cells, thrombocytopenia, and a decline in immunity.
   5. The cause is unknown and appears to involve genetically damaged cells, leading to the transformation of cells from a normal state to a malignant state.
   6. Risk factors include genetic, viral, immunological, and environmental factors and exposure to radiation, chemicals, and medications, such as previous chemotherapy.
B. Assessment

1. Anorexia, fatigue, weakness, weight loss
2. Anemia
3. Overt bleeding (nosebleeds, gum bleeding, rectal bleeding, hematuria, increased menstrual flow) and occult bleeding (e.g., as detected in a fecal occult blood test)
4. Ecchymoses, petechiae
5. Prolonged bleeding after minor abrasions or lacerations
6. Elevated temperature
7. Enlarged lymph nodes, spleen, liver
8. Palpitations, tachycardia, orthostatic hypotension
9. Pallor and dyspnea on exertion
10. Headache
11. Bone pain and joint swelling
12. Normal, elevated, or reduced WBC count
13. Decreased hemoglobin and hematocrit levels
14. Decreased platelet count
15. Positive bone marrow biopsy identifying leukemic blast–phase cells

C. Infection

1. Infection can occur through autocontamination or cross-contamination. The WBC count may be extremely low during the period of greatest bone marrow depression, known as the nadir.
2. Common sites of infection are the skin, respiratory tract, and gastrointestinal tract.
3. Initiate protective isolation procedures.
4. Ensure frequent and thorough hand washing by the client, family, and health care providers.
5. Staff and visitors with known infections or exposure to communicable diseases should avoid contact with the client.
6. Use strict aseptic technique for all procedures.
7. Keep supplies for the client separate from supplies for other clients; keep frequently used equipment in the room for the client’s use only.
8. Limit the number of staff entering the client’s room to reduce the risk of cross-infection.
9. Maintain the client in a private room with the door closed.
10. Place the client in a room with high-efficiency particulate air filtration or a laminar airflow system if possible.
11. Reduce exposure to environmental organisms by eliminating fresh or raw fruits and vegetables (low-bacteria diet) from the diet; eliminate fresh flowers and live plants from the client’s room and avoid leaving standing water in the client’s room.
12. Be sure that the client’s room is cleaned daily.
13. Assist the client with daily bathing, using an antimicrobial soap.
14. Assist the client to perform oral hygiene frequently.
15. Initiate a bowel program to prevent constipation and prevent rectal trauma.
16. Avoid invasive procedures such as injections, insertion of rectal thermometers, and urinary catheterization.
17. Change wound dressings daily, and inspect the wounds for redness, swelling, or drainage.
18. Assess the urine for cloudiness and other characteristics of infection.
19. Assess skin and oral mucous membranes for signs of infection (Box 44-8).
20. Auscultate lung sounds, and encourage the client to cough and deep breathe.
21. Monitor temperature, pulse, respirations, blood pressure, and for pain.
22. Monitor WBC and neutrophil counts.
23. Notify the PHCP if signs of infection are present, and prepare to obtain specimens for culture of the blood, open lesions, urine, and sputum; chest radiograph may also be prescribed.
25. Instruct the client to avoid crowds and those with infections.
26. Instruct the client about a low-bacteria diet.
27. Instruct the client to avoid activities that expose the client to infection, such as changing a pet’s litter box or working with house plants or in the garden.
28. Instruct the client that neither they nor their household contacts should receive immunization with a live virus such as measles, mumps, rubella, polio, varicella, shingles, and some influenza, including the H1N1 vaccine.

Infection is a major cause of death in the immunosuppressed client.

D. Bleeding
1. During the period of greatest bone marrow suppression (the nadir), the platelet count may be extremely low.

2. The client is at risk for bleeding when the platelet count falls below 50,000 mm$^3$ ($50 \times 10^9$/L), and spontaneous bleeding frequently occurs when the platelet count is lower than 20,000 mm$^3$ ($20 \times 10^9$/L).

3. Clients with platelet counts lower than 20,000 mm$^3$ ($20 \times 10^9$/L) may need a platelet transfusion.

4. For clients with anemia and fatigue, packed red blood cells may be prescribed.

5. Monitor laboratory values.

6. Examine the client for signs and symptoms of bleeding, such as petechiae; examine all body fluids and excrement for the presence of blood.

7. Handle the client gently; use caution when taking blood pressures to prevent skin injury.

8. Monitor for signs of internal hemorrhage (e.g., pain, rapid and weak pulse, increased abdominal girth, abdomen guarding, change in mental status).

9. Provide soft foods that are cool to warm to avoid oral mucosa damage.

10. Avoid injections, if possible, to prevent trauma to the skin and bleeding; apply firm and gentle pressure to a needle-stick site for at least 5 minutes, or longer if needed.

11. Pad side rails and sharp corners of the bed and furniture.

12. Avoid rectal suppositories, enemas, and thermometers.

13. If the female client is menstruating, count the number of pads or tampons used.

15. Instruct the client to use a soft toothbrush and avoid dental floss.

16. Instruct the client to use only an electric razor for shaving.

17. Instruct the client to avoid blowing the nose.

18. Discourage the client from engaging in activities involving the use of sharp objects; contact sports also need to be avoided.

19. Instruct the client to avoid using NSAIDs and products that contain aspirin.

---

E. Fatigue and nutrition

1. Assist the client in selecting a well-balanced diet.

2. Provide small, frequent meals (high calorie, high protein, high carbohydrate) that require little chewing...
to reduce energy expenditure at mealtimes.
3. Assist the client in self-care and mobility activities.
4. Allow adequate rest periods during care.
5. Do not perform activities unless they are essential; assist the client in scheduling important or pleasurable activities during periods of highest energy.
6. Administer blood products for anemia as prescribed.

F. Additional interventions
1. Chemotherapy
   a. Induction therapy is aimed at achieving a rapid, complete remission of all manifestations of the disease.
   b. Consolidation therapy is administered early in remission with the aim of curing.
   c. Maintenance therapy may be prescribed for months or years after successful induction and consolidation therapy; the aim is to maintain remission.
2. Administer antibiotic, antibacterial, antiviral, and antifungal medications as prescribed.
3. Administer colony-stimulating factors as prescribed.
4. Administer blood replacements as prescribed.
5. Maintain infection and bleeding precautions.
6. Prepare the client for transplantation if indicated.
7. Instruct the client in appropriate home care measures.
8. Provide psychosocial support and support services for home care.

X. Lymphoma: Hodgkin’s Disease

A. Description
1. Lymphomas, classified as Hodgkin’s and non-Hodgkin’s depending on the cell type, are characterized by abnormal proliferation of lymphocytes.
2. Hodgkin’s disease is a malignancy of the lymph nodes that originates in a single lymph node or a chain of nodes.
3. Metastasis occurs to other, adjacent lymph structures and eventually invades nonlymphoid tissue.
4. The disease usually involves lymph nodes, tonsils, spleen, and bone marrow and is characterized by the presence of Reed-Sternberg cells in the nodes.
5. Possible causes include viral infections; clients treated with combination chemotherapy for Hodgkin’s disease have a greater risk of developing acute leukemia and non-Hodgkin’s lymphoma, among other secondary malignancies.
6. Prognosis depends on the stage of the disease.

B. Assessment
   1. Fever
   2. Malaise, fatigue, and weakness
   3. Night sweats
   4. Loss of appetite and significant weight loss
   5. Anemia and thrombocytopenia
   6. Enlarged lymph nodes, spleen, and liver
      7. Positive biopsy of lymph nodes, with cervical nodes most often affected first
      8. Presence of Reed-Sternberg cells in nodes
      9. Positive computed tomography (CT) scan of the liver and spleen

C. Interventions
   1. For earlier stages (stages I and II), without mediastinal node involvement, the treatment of choice is extensive external radiation of the involved lymph node regions.
   2. With more extensive disease, radiation and multiagent chemotherapy are used.
   3. Monitor for side effects related to chemotherapy or radiation therapy.
   4. Monitor for signs of infection and bleeding.
   5. Maintain infection and bleeding precautions.
   6. Discuss the possibility of sterility with the client receiving chemotherapy and/or radiation, and inform the client of fertility options such as sperm banking.

XI. Multiple Myeloma
   A. Description
      1. A malignant proliferation of plasma cells within the bone
      2. Excessive numbers of abnormal plasma cells invade the bone marrow and ultimately destroy bone; invasion of the lymph nodes, spleen, and liver occurs.
      3. The abnormal plasma cells produce an abnormal antibody (myeloma protein or the Bence Jones protein) found in the blood and urine.
      4. Multiple myeloma causes decreased production of immunoglobulin and antibodies and increased levels of uric acid and calcium, which can lead to kidney failure.
      5. The disease typically develops slowly, and the cause is unknown.

   B. Assessment
1. Bone (skeletal) pain, especially in the ribs, spine, and pelvis
2. Weakness and fatigue
3. Recurrent infections
4. Anemia
5. Urinalysis shows Bence Jones proteinuria and elevated total serum protein level.
6. Osteoporosis (bone loss and the development of pathological fractures)
7. Thrombocytopenia and leukopenia
8. Elevated calcium and uric acid levels
9. Kidney failure
10. Spinal cord compression and paraplegia
11. Bone marrow aspiration shows an abnormal number of immature plasma cells.

The client with multiple myeloma is at risk for pathological fractures. Therefore, provide skeletal support during moving, turning, and ambulating and provide a hazard-free environment.

C. Interventions

1. Administer chemotherapy as prescribed.
2. Provide supportive care to control symptoms and prevent complications, especially bone fractures, hypercalcemia, kidney failure, and infections.
3. Maintain neutropenic and bleeding precautions as necessary.
4. Monitor for signs of bleeding, infection, and skeletal fractures.
5. Encourage the consumption of at least 2 L of fluids per day to offset potential problems associated with hypercalcemia, hyperuricemia, and proteinuria, and encourage additional fluid as indicated and tolerated.
7. Encourage ambulation to prevent renal problems and to slow down bone resorption.
8. Administer IV fluids and diuretics as prescribed to increase renal excretion of calcium.
9. Administer blood transfusions as prescribed for anemia.
10. Administer analgesics as prescribed and provide nonpharmacological therapies to control pain.
11. Administer antibiotics as prescribed for infection.
12. Prepare the client for local radiation therapy if prescribed.
13. Instruct the client in home care measures and the signs and symptoms of infection.
14. Administer bisphosphonate medications as prescribed to slow bone damage and reduce pain and risk of fractures.

XII. Testicular Cancer
A. Description
1. Testicular cancer arises from germinal epithelium from the sperm-producing germ cells or from nongerminal epithelium from other structures in the testicles.
2. Testicular cancer most often occurs between the ages of 15 and 40 years.
3. The cause of testicular cancer is unknown, but a history of undescended testicle (cryptorchidism) and genetic predisposition have been associated with testicular tumor development.
4. Metastasis occurs to the lung, liver, bone, and adrenal glands via the blood and to the retroperitoneal lymph nodes via lymphatic channels.

B. Early detection: Perform monthly testicular self-examination (Fig. 44-1).
1. Performing testicular self-examination: Perform monthly; a day of the month is selected and the examination is performed on the same day each month.
2. Client instructions (see Fig. 44-1)

C. Assessment
1. Painless testicular swelling occurs.
2. “Dragging” or “pulling” sensation is experienced in the scrotum.
3. Palpable lymphadenopathy, abdominal masses, and gynecomastia may indicate metastasis.
4. Late signs include back or bone pain and respiratory symptoms.

D. Interventions
1. Administer chemotherapy as prescribed.
2. Prepare the client for radiation therapy as prescribed.
3. Prepare the client for unilateral orchiectomy, if prescribed, for diagnosis and primary surgical management or radical orchiectomy (surgical removal of the affected testis, spermatic cord, and regional lymph nodes).
4. Prepare the client for retroperitoneal lymph node dissection, if prescribed, to stage the disease and reduce tumor volume so that chemotherapy and radiation therapy are more effective.
5. Discuss reproduction, sexuality, and fertility information and options with the client.
6. Identify reproductive options such as sperm storage, donor insemination, and adoption.

E. Postoperative interventions
1. Monitor for signs of bleeding and wound infection; antibiotics may be administered to prevent wound infection.
2. Monitor intake and output.
3. Provide and explain pain management methods; to reduce swelling in the first 48 hours, apply an ice pack with an intervening protective layer of cloth.
4. Notify the PHCP if chills, fever, increasing pain or tenderness at the incision site, or drainage from the incision occurs.
5. After the orchiectomy, instruct the client to avoid heavy lifting and strenuous activity for the length of time prescribed by the PHCP.
6. Instruct the client to perform a monthly testicular self-examination on the remaining testicle (see Fig. 44-1).
7. Inform the client that sutures will be removed approximately 7 to 10 days after surgery.

XIII. Cervical Cancer
A. Description
1. Preinvasive cancer is limited to the cervix (Box 44-9).
2. Invasive cancer is in the cervix and other pelvic structures.
3. Metastasis usually is confined to the pelvis, but distant metastasis occurs through lymphatic spread.
4. Premalignant changes are described on a continuum from dysplasia, which is the earliest premalignancy change, to carcinoma in situ, the most advanced premalignant change.

B. Risk factors
1. Human papillomavirus (HPV) infection (vaccination against HPV is effective to avoid HPV infection, and thus cervical cancer)
2. Cigarette smoking, both active and passive
3. Reproductive behavior, including early first intercourse (before age 17 years), multiple sex partners, or male partners with multiple sex partners
4. Screening via regular gynecological examinations and Pap test, with treatment of precancerous abnormalities, decreases the incidence and mortality of cervical cancer.

C. Assessment
1. Painless vaginal postmenstrual and postcoital bleeding
2. Foul-smelling or serosanguineous vaginal discharge
3. Pelvic, lower back, leg, or groin pain
4. Anorexia and weight loss
5. Leakage of urine and feces from the vagina
6. Dysuria
7. Hematuria
8. Cytological changes on Pap test

D. Interventions (Box 44-10)

E. Laser therapy
1. Laser therapy is used when all boundaries of the lesion are visible during colposcopic examination.
2. Energy from the beam is absorbed by fluid in the tissues, causing them to vaporize.
3. Minimal bleeding is associated with the procedure.
4. Slight vaginal discharge is expected following the procedure, and healing occurs in 6 to 12 weeks.

F. Cryosurgery
1. Cryosurgery involves freezing of the tissues, using a probe, with subsequent necrosis and sloughing.
2. No anesthesia is required, although cramping may occur during the procedure.
3. A heavy watery discharge will occur for several weeks following the procedure.
4. Instruct the client to avoid intercourse and the use of tampons while the discharge is present.

G. Conization
1. A cone-shaped area of the cervix is removed.
2. Conization allows the woman to retain reproductive capacity.
3. Long-term follow-up care is needed, because new lesions can develop.
4. The risks of the procedure include hemorrhage, uterine perforation, incompetent cervix, cervical stenosis, and preterm labor in future pregnancies.

H. Hysterectomy
1. Description
   a. Hysterectomy is performed for microinvasive cancer if childbearing is
not desired.

b. A vaginal approach is most commonly used.

c. A radical hysterectomy and bilateral lymph node dissection may be performed for cancer that has spread beyond the cervix but not to the pelvic wall.

2. Postoperative interventions

a. Monitor vital signs
b. Assist with coughing and deep-breathing exercises.
c. Assist with range-of-motion exercises and provide early ambulation.
d. Apply antiembolism stockings or sequential compression devices as prescribed.
e. Monitor intake and output, urinary catheter drainage, and hydration status.
f. Monitor bowel sounds.
g. Assess incision site for signs of infection.
h. Administer pain medication as prescribed.
i. Instruct the client to limit stair climbing for 1 month as prescribed and to avoid tub baths and sitting for long periods.
j. Avoid strenuous activity or lifting anything weighing more than 20 pounds (9 kg).
k. Instruct the client to consume foods that promote tissue healing.
l. Instruct the client to avoid sexual intercourse for 3 to 6 weeks as prescribed.
m. Instruct the client in the signs associated with complications.

I. Pelvic exenteration (Box 44-11)

1. Description

a. Pelvic exenteration, the removal of all
pelvic contents, including bowel, vagina, and bladder, is a radical surgical procedure performed for recurrent cancer if no evidence of tumor outside the pelvis and no lymph node involvement exist.

b. When the bladder is removed, an ileal conduit is created and located on the right side of the abdomen to divert urine.

c. A colostomy may need to be created on the left side of the abdomen for the passage of feces.

2. Postoperative interventions

   a. Similar to postoperative interventions following hysterectomy.
   b. Monitor for signs of altered respiratory status.
   c. Monitor incision site for infection.
   d. Monitor intake and output and for signs of dehydration.
   e. Monitor for hemorrhage, shock, and deep vein thrombosis.
   f. Apply antiembolism stockings or sequential compression devices as prescribed.
   g. Administer prophylactic heparin as prescribed.
   h. Administer perineal irrigations and sitz baths as prescribed.
   i. Instruct the client to avoid strenuous activity for 6 months.
   j. Instruct the client that the perineal opening, if present, may drain for several months.
   k. Instruct the client in the care of the ileal conduit and colostomy, if created.
   l. Provide sexual counseling, because vaginal intercourse is not possible after anterior and total pelvic exenteration.

XIV. Ovarian Cancer

A. Description

1. Ovarian cancer grows rapidly, spreads fast, and is often bilateral.

2. Metastasis occurs by direct spread to the organs in the pelvis, by distal spread through lymphatic drainage, or by peritoneal seeding.
3. In its early stages, ovarian cancer is often asymptomatic; because most women are diagnosed in advanced stages, ovarian cancer has a higher mortality rate than any other cancer of the female reproductive system, particularly among white women between 55 and 65 years of age of North American or European descent.

4. An exploratory laparotomy is performed to diagnose and stage the tumor.

5. A transvaginal ultrasound may also be done for screening purposes but will not provide a definitive diagnosis.

B. Assessment

1. Abdominal discomfort or swelling
2. Gastrointestinal disturbances
3. Dysfunctional vaginal bleeding
4. Abdominal mass
5. Elevated tumor marker (i.e., CA-125)

C. Interventions

1. External radiation may be used if the tumor has invaded other organs; intraperitoneal radioisotopes may be instilled for stage I disease.
2. Chemotherapy is used postoperatively for most stages of ovarian cancer.
3. Intraperitoneal chemotherapy involves the instillation of chemotherapy into the abdominal cavity.
4. Total abdominal hysterectomy and bilateral salpingo-oophorectomy with tumor debulking may be necessary.

XV. Endometrial (Uterine) Cancer

A. Description

1. Endometrial cancer is a slow-growing tumor arising from the endometrial mucosa of the uterus, associated with the menopausal years.
2. Metastasis occurs through the lymphatic system to the ovaries and pelvis; via the blood to the lungs, liver, and bone; or intra-abdominally to the peritoneal cavity.

B. Risk factors

1. Use of estrogen replacement therapy (ERT)
2. Nulliparity
3. Polycystic ovary disease
4. Increased age
5. Late menopause
6. Family history of uterine cancer or hereditary nonpolyposis colorectal cancer
7. Obesity
8. Hypertension
9. Diabetes mellitus

C. Assessment
1. Abnormal bleeding, especially in postmenopausal women
2. Vaginal discharge
3. Low back, pelvic, or abdominal pain (pain occurs late in the disease process)
4. Enlarged uterus (in advanced stages)

D. Nonsurgical interventions
1. External or internal radiation is used alone or in combination with surgery, depending on the stage of cancer.
2. Chemotherapy is used to treat advanced or recurrent disease.
3. Progesterone therapy with medication may be prescribed for estrogen-dependent tumors.
4. Antiestrogen medication may also be prescribed.

E. Surgical interventions: Total abdominal hysterectomy and bilateral salpingo-oophorectomy

XVI. Breast Cancer

A. Description
1. Breast cancer is classified as invasive when it penetrates the tissue surrounding the mammary duct and grows in an irregular pattern.
2. Metastasis occurs via lymph nodes.
3. Common sites of metastasis are the bone and lungs; metastasis may also occur to the brain and liver.
4. Diagnosis is made by breast biopsy through a needle aspiration or by surgical removal of the tumor with microscopic examination for malignant cells.

B. Risk factors
1. Age
2. Family history of breast cancer due to genetic predisposition
3. Early menarche and late menopause
4. Previous cancer of the breast, uterus, or ovaries
5. Nulliparity, late first birth
6. Obesity
7. High-dose radiation exposure to chest

C. Assessment
1. Mass felt during BSE (usually felt in the upper outer quadrant, beneath the nipple, or in axilla)
2. Presence of the lesion on mammography
3. A fixed, irregular nonencapsulated mass; typically
painless except in the late stages
4. Asymmetry
5. Bloody or clear nipple discharge
6. Nipple retraction or elevation
7. Skin dimpling, retraction, or ulceration
8. Skin edema or peau d’orange skin
9. Axillary lymphadenopathy
10. Lymphedema of the affected arm
11. Symptoms of bone or lung metastasis in late stage

D. Early detection: Regular BSE
1. Performing BSE
   a. Perform regularly 7 to 10 days after menses.
   b. Postmenopausal clients or clients who have had a hysterectomy should perform BSE regularly as well.
2. Client instructions (Fig. 44-2)

E. Nonsurgical interventions
1. Chemotherapy
2. Radiation therapy
3. Hormonal manipulation via the use of medication in postmenopausal women or other medications for estrogen receptor–positive tumors
4. Monoclonal antibodies such as trastuzumab for human epidermal growth factor receptor 2–positive (HER-2 +) breast cancer

F. Surgical interventions: Surgical breast procedures, with possible breast reconstruction (Box 44-12)

G. Postoperative interventions
1. Monitor vital signs.
2. Position the client in a semi-Fowler’s position; turn from the back to the unaffected side, with the affected arm elevated above the level of the heart to promote drainage and prevent lymphedema.
3. Encourage coughing and deep breathing.
4. If a drain (usually a Jackson-Pratt) is in place, maintain suction and record the amount of drainage and drainage characteristics; teach the client about home management of the drain (Fig. 44-3).
5. Assess operative site for infection, swelling, or the presence of fluid collection under the skin flaps or in the arm.
6. Monitor incision site for restriction of dressing, impaired sensation, or color changes of the skin.
7. If breast reconstruction was performed, the client will
return from surgery usually with a surgical brassiere and a prosthesis in place.
8. Provide the use of a pressure sleeve as prescribed if edema is severe.
9. Maintain fluid and electrolyte balance; administer diuretics and provide a low-salt diet as prescribed for severe lymphedema.
10. Consult with the PHCP and physical therapist regarding the appropriate exercise program, and assist the client with prescribed exercise.
11. Instruct the client about home care measures (Box 44-13).

\[\text{No IVs, no injections, no blood pressure measurements, and no venipunctures should be done in the arm on the side of the mastectomy. The arm on the side of the mastectomy is protected, and any intervention that could traumatize the affected arm is avoided because of the risk for lymphedema on this side.}\]

XVII. Esophageal Cancer
A. Description
1. Esophageal cancer is a malignancy found in the esophageal mucosa, formed by squamous cell carcinoma (SCC) or adenocarcinoma.
2. The cause is unknown but major risk factors include cigarette smoking, alcohol consumption, chronic reflux, Barrett’s esophagus, and vitamin deficiencies.
3. Complications include dysphagia, painful swallowing, loss of appetite, and malaise.
4. The goal of treatment is to inhibit tumor growth and maintain nutrition.

B. Assessment
1. Dysphagia
2. Odynophagia
3. Epigastric pain or sternal pain
C. Interventions
   1. Monitor nutritional status, including daily weight, intake and output, and calories consumed.
   2. Instruct the client about diet changes that make eating easier and less painful.
   3. Prepare the client for chemotherapy and radiation as prescribed.
   4. Prepare the client for surgical resection of the tumor as prescribed.

XVIII. Gastric Cancer
A. Description
1. Gastric cancer is a malignant growth of the mucosal
cells in the inner lining of the stomach, with invasion to the muscle and beyond in advanced disease.

2. No single causative agent has been identified, but it is believed that *H. pylori* infection and a diet of smoked, highly salted, processed, or spiced foods have carcinogenic effects; other risk factors include smoking, alcohol and nitrate ingestion, and a history of gastric ulcers.

3. Complications include hemorrhage, obstruction, metastasis, and dumping syndrome.

4. The goal of treatment is to remove the tumor and provide a nutritional program.

B. Assessment

1. Early
   a. Indigestion
   b. Abdominal discomfort
   c. Full feeling
   d. Epigastric, back, or retrosternal pain

2. Late
   a. Weakness and fatigue
   b. Anorexia and weight loss
   c. Nausea and vomiting
   d. A sensation of pressure in the stomach
   e. Dysphagia and obstructive symptoms
   f. Iron deficiency anemia
   g. Ascites
   h. Palpable epigastric mass

C. Interventions

1. Monitor vital signs.
2. Monitor hemoglobin and hematocrit and administer blood transfusions as prescribed.
4. Assess nutritional status; encourage small, bland, easily digestible meals with vitamin and mineral supplements.
5. Administer pain medication as prescribed.
6. Prepare the client for chemotherapy or radiation therapy as prescribed.
7. Prepare the client for surgical resection of the tumor as prescribed (*Box 44-14*).

D. Postoperative interventions

1. Monitor vital signs.
2. Place in Fowler’s position for comfort.
3. Administer analgesics and antiemetics, as prescribed.
4. Monitor intake and output; administer fluids and electrolyte replacement by IV as prescribed; administer parenteral nutrition as indicated.
5. Maintain NPO (nothing by mouth) status as prescribed for 1 to 3 days until peristalsis returns; assess for bowel sounds.

6. Monitor nasogastric suction. Following gastrectomy, drainage from the nasogastric tube is normally bloody for 24 hours postoperatively, changes to brown-tinged, and is then yellow or clear.

7. Do not irrigate or remove the nasogastric tube (follow agency procedures); assist the PHCP with irrigation or removal.

8. Advance the diet from NPO to sips of clear water to 6 small bland meals a day, as prescribed.

9. Monitor for complications such as hemorrhage, dumping syndrome, diarrhea, hypoglycemia, and vitamin B₁₂ deficiency.

XIX. Pancreatic Cancer

A. Description

1. Most pancreatic tumors are highly malignant, rapidly growing adenocarcinomas originating from the epithelium of the ductal system.

2. Pancreatic cancer is associated with increased age, a history of diabetes mellitus, alcohol use, history of previous pancreatitis, smoking, ingestion of a high-fat diet, and exposure to environmental chemicals.

3. Symptoms usually do not occur until the tumor is large; therefore, the prognosis is poor.

4. Endoscopic retrograde cholangiopancreatography for visualization of the pancreatic duct and biliary system and collection of tissue and secretions may be done.

B. Assessment

1. Nausea and vomiting
2. Jaundice
3. Unexplained weight loss
4. Clay-colored stools
5. Glucose intolerance
6. Abdominal pain

C. Interventions

1. Radiation
2. Chemotherapy
3. Whipple procedure, which involves a pancreaticoduodenectomy with removal of the distal third of the stomach, pancreaticojejunostomy, gastrojejunostomy, and choledochojejunostomy (Fig. 44-4)
4. Postoperative care measures and complications are similar to those for the care of a client with pancreatitis and the client following gastric surgery; monitor blood glucose levels for transient hyperglycemia or hypoglycemia resulting from surgical manipulation of the pancreas.

XX. Intestinal Tumors

A. Description
1. Intestinal tumors are malignant lesions that develop in the cells lining the bowel wall or develop as adenomatous polyps in the colon or rectum.
2. Tumor spread is by direct invasion and through the lymphatic and circulatory systems.
3. Complications include bowel perforation with peritonitis, abscess and fistula formation, hemorrhage, and complete intestinal obstruction.

B. Risk factors for colorectal cancer
1. Age older than 50 years
2. Familial polyposis, family history of colorectal cancer
3. Previous colorectal polyps, history of colorectal cancer
4. History of chronic inflammatory bowel disease
5. History of ovarian or breast, endometrial, and stomach cancers

C. Assessment
1. Blood in stool (most common manifestation) detected by fecal occult blood testing, sigmoidoscopy, and colonoscopy
2. Anorexia, vomiting, and weight loss
3. Anemia
4. Abnormal stools
   a. Ascending colon tumor: Diarrhea
   b. Descending colon tumor: Constipation or some diarrhea, or flat, ribbon-like stool caused by a partial obstruction
   c. Rectal tumor: Alternating constipation and diarrhea
5. Guarding or abdominal distention, abdominal mass (late sign)
6. Cachexia (late sign)
7. Masses noted on barium enema, colonoscopy, CT scan, sigmoidoscopy

D. General interventions
1. Monitor for signs of complications, which include bowel perforation with peritonitis, abscess or...
fistula formation (fever associated with pain), hemorrhage (signs of shock), and complete intestinal obstruction.

2. Monitor for signs of bowel perforation, which include low blood pressure, rapid and weak pulse, distended abdomen, and elevated temperature.

3. Monitor for signs of intestinal obstruction, which include vomiting (may be fecal contents), pain, constipation, and abdominal distention; provide comfort measures.

4. Note that an early sign of intestinal obstruction is increased peristaltic activity, which produces an increase in bowel sounds; as the obstruction progresses, hypoactive bowel sounds may be heard.

5. Prepare for radiation preoperatively to facilitate surgical resection, and postoperatively to decrease the risk of recurrence or to reduce pain, hemorrhage, bowel obstruction, or metastasis.

E. Nonsurgical interventions
1. Preoperative radiation for local control and postoperative radiation for palliation may be prescribed.

2. Postoperative chemotherapy to control symptoms and the spread of disease

F. Surgical interventions: Bowel resection, local lymph node resection, and creation of a colostomy or ileostomy

G. Colostomy, ileostomy
1. Preoperative interventions
   a. Consult with the enterostomal therapist to assist in identifying optimal placement of the ostomy.
   b. Instruct the client in prescribed preoperative diet; bowel preparation (laxatives and enemas) may be prescribed per surgeon preference.
   c. Intestinal antiseptics and antibiotics may be prescribed to decrease the bacterial content of the colon and to reduce the risk of infection from the surgical procedure.

2. Postoperative: Colostomy
   a. If a pouch system is not in place, apply a petroleum jelly gauze over the stoma to keep it moist, covered with a dry sterile dressing; place a pouch system on the stoma as soon as possible.
   b. Monitor the pouch system for proper fit
and signs of leakage; empty the pouch when one-third full.
c. Monitor the stoma for size, unusual bleeding, color changes, or necrotic tissue.
d. Note that the normal stoma color is red or pink, indicating high vascularity.
e. Note that a pale pink stoma indicates low hemoglobin and hematocrit levels.
f. Assess the functioning of the colostomy.
g. Expect that stool will be liquid postoperatively but will become more solid, depending on the area of the colostomy.
h. Expect liquid stool from an ascending colon colostomy, loose to semifomed stool from a transverse colon colostomy, or close to normal stool from a descending colon colostomy.
i. Fecal matter should not be allowed to remain on the skin.
j. Administer analgesics and antibiotics as prescribed.
k. Irrigate perineal wound if present and if prescribed, and monitor for signs of infection; provide comfort measures for perineal itching and pain.
l. Instruct the client to avoid foods that cause excessive gas formation and odor.
m. Instruct the client in stoma care and irrigations as prescribed.
n. Instruct the client on when to resume normal activities, including work, travel, and sexual intercourse, as prescribed; provide psychosocial support.

3. Postoperative: Ileostomy
   a. Healthy stoma is red in color.
   b. Postoperative drainage will be dark green and progress to yellow as the client begins to eat.
   c. Stool is liquid.
   d. Risk for dehydration and electrolyte imbalance exists.
XXI. Lung Cancer
A. Description
1. Lung cancer is a malignant tumor of the bronchi and peripheral lung tissue.
2. The lungs are a common target for metastasis from other organs.
3. Bronchogenic cancer (tumors originate in the epithelium of the bronchus) spreads through direct extension and lymphatic dissemination.
4. Classified according to histological cell type; types include small cell lung cancer (SCLC) and non–small cell lung cancer (NSCLC); epidermal (squamous cell), adenocarcinoma, and large cell anaplastic carcinoma are classified as NSCLC because of their similar responses to treatment.
5. Diagnosis is made by a chest x-ray study, CT and PET scan, or magnetic resonance imaging (MRI), which shows a lesion or mass, and by bronchoscopy and sputum studies, which demonstrate a positive cytological study for cancer cells.

B. Causes
1. Cigarette smoking; also exposure to “passive” tobacco smoke
2. Exposure to environmental and occupational pollutants

C. Assessment
1. Cough
2. Wheezing, dyspnea
3. Hoarseness
4. Hemoptysis, blood-tinged or purulent sputum
5. Chest pain
6. Anorexia and weight loss
7. Weakness
8. Diminished or absent breath sounds, respiratory changes

D. Interventions
1. Monitor vital signs.
2. Monitor breathing patterns and breath sounds and for signs of respiratory impairment; monitor for hemoptysis.
3. Assess for tracheal deviation.
4. Administer analgesics as prescribed for pain management.
5. Place in a Fowler’s position to help ease breathing.

6. Administer oxygen as prescribed and humidification to moisten and loosen secretions.

7. Monitor pulse oximetry.

8. Provide respiratory treatments as prescribed.

9. Administer bronchodilators and corticosteroids as prescribed to decrease bronchospasm, inflammation, and edema.

10. Provide a high-calorie, high-protein, high-vitamin diet.

11. Provide activity as tolerated, rest periods, and active and passive range-of-motion exercises.

E. Nonsurgical interventions

1. Radiation therapy may be prescribed for localized intrathoracic lung cancer and for palliation of hemoptysis, obstructions, dysphagia, superior vena cava syndrome, and pain.

2. Chemotherapy may be prescribed for treatment of nonresectable tumors or as adjuvant therapy.

F. Surgical interventions

1. Laser therapy: To relieve endobronchial obstruction

2. Thoracentesis and pleurodesis: To remove pleural fluid and relieve hypoxia

3. Thoracotomy (opening into the thoracic cavity) with pneumonectomy: Surgical removal of 1 entire lung

4. Thoracotomy with lobectomy: Surgical removal of 1 lobe of the lung for tumors confined to a single lobe

5. Thoracotomy with segmental resection: Surgical removal of a lobe segment

G. Preoperative interventions

1. Explain the potential postoperative need for chest tubes.

2. Note that closed chest drainage usually is not used for a pneumonectomy, and the serous fluid that accumulates in the empty thoracic cavity eventually consolidates, preventing shifts of the mediastinum, heart, and remaining lung.

H. Postoperative interventions

1. Monitor vital signs.

2. Assess cardiac and respiratory status; monitor lung sounds.
3. Maintain the chest tube drainage system, which drains air and blood that accumulates in the pleural space; monitor for excess bleeding. (See Chapter 69 for care of the client with a chest tube.)

4. Administer oxygen as prescribed.

5. Check the surgeon’s prescriptions regarding client positioning; avoid complete lateral turning.

7. Provide activity as tolerated.

8. Encourage active range-of-motion exercises of the operative shoulder as prescribed.

XXII. Laryngeal Cancer

A. Description

1. Laryngeal cancer is a malignant tumor of the larynx (Fig. 44-5).

2. Laryngeal cancer presents as malignant ulcerations with underlying infiltration and is spread by local extension to adjacent structures in the throat and neck and by the lymphatic system.

3. Diagnosis is made by laryngoscopy and biopsy showing a positive cytological study for cancer cells.

4. Laryngoscopy allows for evaluation of the throat and biopsy of tissues; chest radiography, CT, and MRI are used for staging.

B. Risk factors

1. Cigarette smoking

2. Heavy alcohol use and the combined use of tobacco and alcohol

3. Exposure to environmental pollutants (e.g., asbestos, wood dust)

4. Exposure to radiation

C. Assessment

1. Persistent hoarseness or sore throat and ear pain

2. Painless neck mass

3. Feeling of a lump in the throat

4. Burning sensation in the throat

5. Dysphagia

6. Change in voice quality

7. Dyspnea

8. Weakness and weight loss

9. Hemoptysis
10. Foul breath odor

D. Interventions

1. Place in Fowler’s position to promote optimal air exchange.
3. Monitor for signs of aspiration of food and fluid.
4. Administer oxygen as prescribed.
5. Provide respiratory treatments as prescribed.
6. Provide activity as tolerated.
7. Provide a high-calorie and high-protein diet.
8. Provide nutritional support via parenteral nutrition, nasogastric tube feedings, or gastrostomy or jejunostomy tube, as prescribed.
9. Administer analgesics as prescribed for pain.
10. Encourage clients to stop smoking and drinking alcohol to increase effectiveness of treatments.

E. Nonsurgical interventions

1. Radiation therapy in specified situations
2. Chemotherapy, which may be given in combination with radiation and surgery

F. Surgical interventions

1. The goal is to remove the cancer while preserving as much normal function as possible.
2. Surgical intervention depends on the tumor size, location, and amount of tissue to be resected.
3. Types of resection include cordal stripping, cordectomy, partial laryngectomy, and total laryngectomy.
4. A tracheostomy is performed with a total laryngectomy; this airway opening is permanent and is referred to as a laryngectomy stoma.

G. Preoperative interventions

1. Discuss self-care of the airway, alternative methods of communication, suctioning, pain control methods, the critical care environment, and nutritional support.
2. Encourage the client to express feelings about changes in body image and loss of voice.
3. Describe the rehabilitation program and information about the tracheostomy and suctioning.

H. Postoperative interventions

1. Monitor vital signs.
2. Monitor respiratory status; monitor airway
patency and provide frequent suctioning to remove bloody secretions.

3. Place the client in a high-Fowler’s position.

4. Maintain mechanical ventilator support or a tracheostomy collar with humidification, as prescribed.

5. Monitor pulse oximetry.

6. Maintain surgical drains in the neck area if present.

7. Observe for hemorrhage and edema in the neck.

8. Monitor IV fluids or parenteral nutrition until nutrition is administered via a nasogastric, gastrostomy, or jejunostomy tube.

10. Assess gag and cough reflexes and the ability to swallow.

11. Increase activity as tolerated.

12. Assess the color, amount, and consistency of sputum.

13. Provide stoma and laryngectomy care (Box 44-15).

14. Provide consultation with speech and language pathologist as prescribed.

15. Reinforce method of communication established preoperatively.

16. Prepare the client for rehabilitation and speech therapy (Box 44-16).

XXIII. Prostate Cancer

A. Description

1. Prostate cancer, a slow-growing malignancy of the prostate gland, is a common cancer in American men; most prostate tumors are adenocarcinomas arising from androgen-dependent epithelial cells.

2. The risk increases in men with each decade after the age of 50 years.

3. Prostate cancer can spread via direct invasion of surrounding tissues or by metastasis through the bloodstream and lymphatics, to the bony pelvis and spine.

4. Bone metastasis is a concern, as is spread to the lungs, liver, and kidneys.

5. The cause of prostate cancer is unclear, but advancing age, heavy metal exposure, smoking, and history of sexually transmitted infection are contributing factors; it is more common among men of African American descent.

B. Assessment

1. Asymptomatic in early stages
2. Hard, pea-sized nodule or irregularities palpated on rectal examination
3. Gross, painless hematuria
4. Late symptoms such as weight loss, urinary obstruction, and bone pain radiating from the lumbosacral area down the leg
5. The prostate-specific antigen level is elevated in various noncancerous conditions; therefore, it should not be used as a screening test without a digital rectal examination. It is routinely used to monitor response to therapy.
6. Diagnosis is made through biopsy of the prostate gland.

C. Nonsurgical interventions
1. Prepare the client for hormone manipulation therapy (androgen suppression therapy) as prescribed or active surveillance with prostate-specific antigen (PSA) and digital rectal examination (DRE).
2. Luteinizing hormone may be prescribed to slow the rate of growth of the tumor.
3. Medication adverse effects include reduced libido, hot flashes, breast tenderness, osteoporosis, loss of muscle mass, and weight gain. The client should be informed of these effects.
4. Pain medication, radiation therapy, corticosteroids, and bisphosphonates may be prescribed for palliation of advanced prostate cancer.
5. Prepare the client for external beam radiation or brachytherapy, which may be prescribed alone or with surgery, preoperatively or postoperatively, to reduce the lesion and limit metastasis.
6. Prepare the client for the administration of chemotherapy in cases of hormone treatment resistant tumors.

D. Surgical interventions
1. Prepare the client for orchiectomy (palliative), if prescribed, which will limit the production of testosterone.
2. Prepare the client for prostatectomy, if prescribed.
3. The radical prostatectomy can be performed via a retropubic, perineal, or suprapubic approach.
4. Cryosurgical ablation is a minimally invasive procedure that may be an alternative to radical prostatectomy; liquid nitrogen freezes the gland, and the dead cells are absorbed by the body.

E. Transurethral resection of the prostate (TURP) may be performed for palliation in prostate cancer clients.
1. The procedure involves insertion of a scope into the urethra to excise prostatic tissue.
2. Monitor for hemorrhage; bleeding is common following TURP.
3. Postoperative continuous bladder irrigation (CBI) may be prescribed, which prevents catheter obstruction from clots.
4. Assess for signs of transurethral resection syndrome, which include signs of cerebral edema and increased intracranial pressure, such as increased blood pressure, bradycardia, confusion, disorientation, muscle twitching, visual disturbances, and nausea and vomiting.
5. Antispasmodics may be prescribed for bladder spasm.
6. Instruct the client to monitor and report dribbling or incontinence postoperatively and teach perineal exercises.
7. Sterility is possible following the surgical procedure.

F. Suprapubic prostatectomy
1. Suprapubic prostatectomy is removal of the prostate gland by an abdominal incision with a bladder incision.
2. The client will have an abdominal dressing that may drain copious amounts of urine, and the abdominal dressing will need to be changed frequently.
3. Severe hemorrhage is possible, and monitoring for blood loss is an important nursing intervention.
4. Antispasmodics may be prescribed for bladder spasms.
5. CBI is prescribed and carried out to maintain pink-colored urine.
6. Sterility occurs with this procedure.

G. Retropubic prostatectomy
1. Retropubic prostatectomy is removal of the prostate gland by a low abdominal incision without opening the bladder.
2. Less bleeding occurs with this procedure compared with the suprapubic procedure, and the client experiences fewer bladder spasms.
3. Abdominal drainage is minimal.
4. CBI may be used.
5. Sterility occurs with this procedure.

H. Perineal prostatectomy
1. The prostate gland is removed through an incision made between the scrotum and anus.
2. Minimal bleeding occurs with this procedure.
3. The client needs to be monitored closely for infection, because the risk of infection is increased with this type of prostatectomy.
4. Urinary incontinence is common.
5. The procedure causes sterility.
6. Teach the client how to perform perineal exercises.

I. Postoperative interventions

1. Monitor vital signs.
2. Monitor urinary output and urine for hemorrhage or clots.
3. Increase fluids to 2400 to 3000 mL/day, unless contraindicated.
4. Monitor for arterial bleeding as evidenced by bright red urine with numerous clots; if it occurs, increase CBI and notify the surgeon immediately.
5. Monitor for venous bleeding as evidenced by burgundy-colored urine output; if it occurs, inform the surgeon, who may apply traction on the catheter.
6. Monitor hemoglobin and hematocrit levels.
7. Expect red to light pink urine for 24 hours, turning to amber in 3 days.
8. Ambulate the client as early as possible and as soon as urine begins to clear in color.
9. Inform the client that a continuous feeling of an urge to void is normal.
10. Instruct the client to avoid attempts to void around the catheter, because this will cause bladder spasms.
11. Administer antibiotics, analgesics, stool softeners, and antispasmodics as prescribed.
12. Monitor the 3-way urinary catheter, which usually has a 30- to 45-mL retention balloon.
13. Maintain CBI with sterile bladder irrigation solution as prescribed to keep the catheter free of obstruction and keep the urine pink in color (Box 44-17).

Following TURP, monitor for transurethral resection syndrome or severe hyponatremia (water intoxication) caused by the excessive absorption of bladder irrigation during surgery. (Signs include altered mental status, bradycardia, increased blood pressure, and confusion.)

J. Postoperative interventions: Suprapubic prostatectomy

1. Monitor suprapubic and urinary catheter drainage.
2. Monitor CBI if prescribed.
3. Note that the urinary catheter will be removed 2 to 4 days postoperatively if the client has a suprapubic
catheter.
4. If prescribed, clamp the suprapubic catheter after the urinary catheter is removed, and instruct the client to attempt to void; after the client has voided, assess the residual urine in the bladder by unclamping the suprapubic catheter and measuring the output.
5. Prepare for removal of the suprapubic catheter when the client consistently empties the bladder and residual urine is 75 mL or less as prescribed.
6. Monitor the suprapubic incision dressing, which may become saturated with urine, until the incision heals; dressing may need to be changed frequently.

**K. Postoperative interventions: Retropubic prostatectomy**

1. Note that because the bladder is not entered, there is no urinary drainage on the abdominal dressing; if urinary or purulent drainage is noted on the dressing, notify the surgeon.
2. Monitor for fever and increased pain, which may indicate an infection.

**L. Postoperative interventions: Perineal prostatectomy**

1. Note that the client will have an incision, which may or may not have a drain.
2. Avoid the use of rectal thermometers, rectal tubes, and enemas, because they may cause trauma and bleeding.

XXIV. Bladder Cancer

**A. Description**

1. Bladder cancer is a papillomatous growth in the bladder urothelium that undergoes malignant changes and that may infiltrate the bladder wall.
2. Predisposing factors include cigarette smoking, exposure to industrial chemicals, and exposure to radiation.
3. Common sites of metastasis include the liver, bones, and lungs.
4. As the tumor progresses, it can extend into the rectum, vagina, other pelvic soft tissues, and retroperitoneal structures.

**B. Assessment**

1. Gross or microscopic, painless hematuria (most common sign)
2. Frequency, urgency, dysuria
3. Clot-induced obstruction
4. Bladder wash specimens and biopsy confirm diagnosis
C. Radiation

1. Radiation therapy is indicated for advanced disease that cannot be eradicated by surgery; palliative radiation may be used to relieve pain and bowel obstruction and control potential hemorrhage and leg edema caused by venous or lymphatic obstruction.

2. Intracavitary radiation may be prescribed, which protects adjacent tissue.

3. External beam radiation combined with chemotherapy or surgery may be prescribed to improve survival.

4. Complications of radiation
   a. Abacterial cystitis
   b. Proctitis
   c. Fistula formation
   d. Ileitis or colitis
   e. Bladder ulceration and hemorrhage

D. Chemotherapy

1. Intravesical instillation
   a. An alkylating chemotherapeutic agent is instilled into the bladder.
   b. This method provides a concentrated topical treatment with little systemic absorption.
   c. The medication is injected into a urethral catheter and retained for 2 hours.
   d. Following instillation, the client’s position is rotated every 15 to 30 minutes, starting in the supine position, to avoid lying on a full bladder.
   e. After 2 hours, the client voids in a sitting position and is instructed to increase fluids to flush the bladder.
   f. Treat the urine as a biohazard and send to the radioisotope laboratory for monitoring.
   g. For 6 hours following intravesical chemotherapy, disinfect the toilet with household bleach after the client has voided.

2. Systemic chemotherapy: Used to treat inoperable tumors or distant metastasis.

3. Complications of chemotherapy
   a. Bladder irritation
   b. Hemorrhagic cystitis

E. Surgical interventions
1. Transurethral resection of bladder tumor
   a. Local resection and fulguration (destruction of tissue by electrical current through electrodes placed in direct contact with the tissue)
   b. Performed for early tumors for cure or for inoperable tumors for palliation

2. Partial cystectomy
   a. Partial cystectomy is the removal of up to half the bladder.
   b. The procedure is done for early-stage tumors and for clients who cannot tolerate a radical cystectomy.
   c. During the initial postoperative period, bladder capacity is reduced greatly to about 60 mL; however, as the bladder tissue expands, the capacity increases to 200 to 400 mL.
   d. Maintenance of a continuous output of urine following surgery is critical to prevent bladder distention and stress on the suture line.
   e. A urethral catheter and a suprapubic catheter may be in place, and the suprapubic catheter may be left in place for 2 weeks until healing occurs.

3. Cystectomy and urinary diversion (Fig. 44-6)
   a. Various surgical procedures are performed to create alternative pathways for urine collection and excretion.
   b. Urinary diversion may be performed with or without cystectomy (bladder removal).
   c. The surgery may be performed in 2 stages if the tumor is extensive, with the creation of the urinary diversion first and the cystectomy several weeks later.
   d. If a radical cystectomy is performed, lower extremity lymphedema may occur as a result of lymph node dissection, and male impotence may occur.

4. Ileal conduit
   a. The ileal conduit is also called a ureteroileostomy, or Bricker’s procedure.
   b. Ureters are implanted into a segment of
the ileum, with the formation of an abdominal stoma.
c. The urine flows into the conduit and is propelled continuously out through the stoma by peristalsis.
d. The client is required to wear an appliance over the stoma to collect the urine (Box 44-18).
e. Complications include obstruction, pyelonephritis, leakage at the anastomosis site, stenosis, hydronephrosis, calculi, skin irritation and ulceration, and stomal defects.

5. Kock pouch
   a. The Kock pouch is a continent internal ileal reservoir created from a segment of the ileum and ascending colon.
   b. The ureters are implanted into the side of the reservoir, and a special nipple valve is constructed to attach the reservoir to the skin.
   c. Postoperatively, the client will have a urinary catheter in place to drain urine continuously until the pouch has healed.
   d. The urinary catheter is irrigated gently with normal saline to prevent obstruction from mucus or clots.
   e. Following removal of the urinary catheter, the client is instructed in how to self-catheterize and to drain the reservoir at 4- to 6-hour intervals (Box 44-19).

6. Indiana pouch
   a. A continent reservoir is created from the ascending colon and terminal ileum, making a pouch larger than the Kock pouch (additional continent reservoirs include the Mainz and Florida pouch systems).
   b. Postoperatively, care is similar to that for the Kock pouch.

7. Creation of a neobladder
   a. Creation of a neobladder is similar to creation of an internal reservoir, with the difference being that instead of emptying through an abdominal stoma, the bladder empties through a
pelvic outlet into the urethra.
b. The client empties the neobladder by relaxing the external sphincter and creating abdominal pressure or by intermittent self-catheterization.

8. Percutaneous nephrostomy or pyelostomy
a. These procedures are used to prevent or treat obstruction.
b. The procedures involve a percutaneous or surgical insertion of a nephrostomy tube into the kidney for drainage.
c. Nursing interventions involve stabilizing the tube to prevent dislodgment and monitoring output.

9. Ureterostomy
a. Ureterostomy may be performed as a palliative procedure if the ureters are obstructed by the tumor.
b. The ureters are attached to the surface of the abdomen, where the urine flows directly into a drainage appliance without a conduit.
c. Potential problems include infection, skin irritation, and obstruction to urinary flow as a result of strictures at the opening.

10. Vesicostomy
a. The bladder is sutured to the abdomen, and a stoma is created in the bladder wall.
b. The bladder empties through the stoma.

F. Preoperative interventions
1. Instruct the client in preoperative, operative, and postoperative management, including diet, medications, nasogastric tube placement, IV lines, NPO status, pain control, coughing and deep breathing, leg exercises, and postoperative activity.
2. Demonstrate appliance application and use for those clients who will have a stoma.
3. Arrange an enterostomal nurse consult and for a visit with a person who has had urinary diversion.
4. Administer antimicrobials for bowel preparation as prescribed.
5. Encourage discussion of feelings, including the effects on sexual activities.

G. Postoperative interventions
Monitor urinary output closely following bladder surgery. Irrigate the ureteral catheter (if present and if prescribed) gently to prevent obstruction. Follow the surgeon’s prescriptions and agency policy regarding irrigation.

1. Monitor vital signs.
2. Assess incision site.
3. Assess stoma (should be red and moist) every hour for the first 24 hours.
4. Monitor for edema in the stoma, which may be present in the immediate postoperative period.
5. Notify the surgeon if the stoma appears dark and dusky (indicates necrosis).
6. Monitor for prolapse or retraction of the stoma.
7. Assess bowel function; monitor for expected return of peristalsis in 3 to 4 days.
8. Maintain NPO status as prescribed until bowel sounds return.
9. Monitor for continuous urine flow (30 to 60 mL/hr).
10. Notify the surgeon if the urine output is less than 30 mL/hr or if no urine output occurs for more than 15 minutes.
11. Ureteral stents or catheters, if present, may be in place for 2 to 3 weeks or until healing occurs; maintain stability with catheters to prevent dislodgment.
12. Monitor for hematuria.
13. Monitor for signs of peritonitis.
14. Monitor for bladder distention following a partial cystectomy.
15. Monitor for shock, hemorrhage, thrombophlebitis, and lower extremity lymphedema after a radical cystectomy.
16. Monitor the urinary drainage pouch for leaks, and check skin integrity (see Box 44-18).
17. Monitor the pH of the urine (do not place the dipstick in the stoma), because highly alkaline or acidic urine can cause skin irritation and facilitate crystal formation.
18. Instruct the client regarding the potential for urinary tract infection or the development of calculi.
19. Instruct the client to assess the skin for irritation, monitor the urinary drainage pouch, and report any leakage.
20. Encourage the client to express feelings about changes in body image, embarrassment, and sexual dysfunction.

XXV. Oncological Emergencies

A. Sepsis and disseminated intravascular coagulation (DIC)
1. Description: The client with cancer is at increased risk for infection, particularly gram-negative organisms, in the bloodstream (sepsis or septicemia) and DIC, a life-threatening problem frequently associated with sepsis.

2. Interventions
   a. Prevent the complication through early identification of clients at high risk for sepsis and DIC.
   b. Maintain strict aseptic technique with the immunocompromised client and monitor closely for infection and signs of bleeding.
   c. Administer antibiotics intravenously as prescribed.
   d. Administer anticoagulants as prescribed during the early phase of DIC.
   e. Administer cryoprecipitated clotting factors, as prescribed, when DIC progresses and hemorrhage is the primary problem.

   Notify the PHCP immediately if signs of an oncological emergency occur.

B. Syndrome of inappropriate antidiuretic hormone (SIADH)
   1. Description
      a. Tumors can produce, secrete, or stimulate substances that mimic antidiuretic hormone.
      b. Mild symptoms include weakness, muscle cramps, loss of appetite, and fatigue; serum sodium levels range from 115 to 120 mEq/L (115 to 120 mmol/L).
      c. More serious signs and symptoms relate to water intoxication and include weight gain, personality changes, confusion, and extreme muscle weakness.
      d. As the serum sodium level approaches 110 mEq/L (110 mmol/L), seizures, coma, and eventually death will occur, unless the condition is treated rapidly.

2. Interventions
   a. Initiate fluid restriction and increased
sodium intake as prescribed.  
b. As prescribed, administer an antagonist to antidiuretic hormone.  
c. Monitor serum sodium levels.  
d. Treat the underlying cause with chemotherapy or radiation to achieve tumor regression.  

C. Spinal cord compression  
1. Description  
a. Spinal cord compression occurs when a tumor directly enters the spinal cord or when the vertebral column collapses from tumor entry, impinging on the spinal cord.  
b. Spinal cord compression causes back pain, usually before neurological deficits occur.  
c. Neurological deficits relate to the spinal level of compression and include numbness; tingling; loss of urethral, vaginal, and rectal sensation; and muscle weakness.  

2. Interventions  
a. Early recognition: Assess for back pain and neurological deficits.  
b. Administer high-dose corticosteroids to reduce swelling around the spinal cord and relieve symptoms.  
c. Prepare the client for immediate radiation and/or chemotherapy to reduce the size of the tumor and relieve compression.  
d. Surgery may need to be performed to remove the tumor and relieve the pressure on the spinal cord.  
e. Instruct the client in the use of neck or back braces if they are prescribed.  

D. Hypercalcemia  
1. Description  
a. Hypercalcemia is a late manifestation of extensive malignancy that occurs most often with bone metastasis, when the bone releases calcium into the bloodstream.  
b. Decreased physical mobility contributes to or worsens hypercalcemia.  
c. Early signs include fatigue, anorexia, nausea, vomiting, constipation, and
polyuria.

d. More serious signs and symptoms include severe muscle weakness, diminished deep tendon reflexes, paralytic ileus, dehydration, and changes in the electrocardiogram.

2. Interventions
   a. Monitor serum calcium level and electrocardiographic changes.
   b. Administer oral or parenteral fluids as prescribed.
   c. Administer medications that lower the calcium level and control nausea and vomiting as prescribed.
   d. Prepare the client for dialysis if the condition becomes life-threatening or is accompanied by renal impairment.
   e. Encourage walking to prevent breakdown of bone.

E. Superior vena cava syndrome
   1. Description
      a. Superior vena cava (SVC) syndrome occurs when the SVC is compressed or obstructed by tumor growth (commonly associated with lung cancer and lymphoma).
      b. Signs and symptoms result from blockage of blood flow in the venous system of the head, neck, and upper trunk.
      c. Early signs and symptoms generally occur in the morning and include edema of the face, especially around the eyes, and tightness of the shirt or blouse collar (Stokes’ sign).
      d. As the condition worsens, edema in the arms and hands, dyspnea, erythema of the upper body, swelling of the veins in the chest and neck, and epistaxis occur.
      e. Life-threatening signs and symptoms include airway obstruction, hemorrhage, cyanosis, mental status changes, decreased cardiac output, and hypotension.
   
   2. Interventions
      a. Assess for early signs and symptoms of SVC syndrome.
b. Place the client in semi-Fowler’s position and administer corticosteroids and diuretics as prescribed.
c. Prepare the client for high-dose radiation therapy to the mediastinal area and possible surgery to insert a metal stent in the vena cava.

F. Tumor lysis syndrome
1. Description
   a. Tumor lysis syndrome occurs when large quantities of tumor cells are destroyed rapidly and intracellular components such as potassium and uric acid are released into the bloodstream faster than the body can eliminate them.
   b. Tumor lysis syndrome can indicate that cancer treatment is destroying tumor cells; however, if left untreated, it can cause severe tissue damage and death.
   c. Hyperkalemia, hyperphosphatemia with resultant hypocalcemia, and hyperuricemia occur; hyperuricemia can lead to acute kidney injury.

2. Interventions
   a. Encourage oral hydration; IV hydration may be prescribed; monitor renal function and intake and output, and ensure that the client is on a renal diet low in potassium and phosphorus.
   b. Administer diuretics to increase the urine flow through the kidneys as prescribed.
   c. Administer medications that increase the excretion of purines, such as allopurinol, as prescribed.
   d. Prepare to administer IV infusion of glucose and insulin to treat hyperkalemia.
   e. Prepare the client for dialysis if hyperkalemia and hyperuricemia persist despite treatment.

XXVI. Anemia
A. Description
   1. Condition in which the blood lacks adequate healthy red blood cells or hemoglobin, with most common causes being acute blood loss, decreased or faulty red blood cell production, or the destruction of red blood
2. There are several types of anemia, with the main types being anemia related to acute and chronic blood loss, anemia of chronic diseases (including cancers, immunodeficiency syndrome, renal disease, liver diseases, and autoimmune conditions), anemias caused by nutritional deficiencies (such as iron, folate, or vitamin B₁₂ deficiency), and hereditary anemias (including sickle cell anemia and thalassemia).

3. Treatment of anemia focuses on treating the cause of the condition and varies based on the type of anemia.

4. Acute blood loss anemia is characterized by normal red blood cell size, shape, and color. Clients at risk include postoperative clients, clients with an active bleeding problem, or immunocompromised clients with a reduction in blood components. Hemoglobin, hematocrit, or red blood cell levels can be low.

B. Assessment
   1. Fatigue
   2. Weakness
   3. Pallor or slight jaundice if red blood cell destruction occurs
   4. Shortness of breath
   5. Dysrhythmias
   6. Chest pain
   7. Tachycardia
   8. Cool extremities

C. Interventions
   1. Administer blood products and hematopoietic medications as prescribed, which are used to treat anemia related to acute and chronic conditions.
   2. Encourage a diet rich in the deficient nutrient if the anemia is caused by malnutrition, such as iron, folate, or vitamin B₁₂ supplementation.
   3. Control and address the source of bleeding if anemia is caused by acute blood loss and assess client for sources of frank and occult bleeding. Contact the PCHP and prepare for replacement therapy if acute blood loss occurs.

XXVII. Iron Deficiency Anemia
   A. Description
      1. Iron stores are depleted, resulting in a decreased iron supply for the manufacture of hemoglobin in red blood cells.
      2. Commonly results from blood loss, increased metabolic demands, syndromes of gastrointestinal malabsorption, and dietary inadequacy.

   B. Assessment
1. Pallor
2. Weakness and fatigue
3. Low hemoglobin, hematocrit, and mean cellular volume (MCV) levels
4. Red blood cells that are microcytic and hypochromic

C. Interventions
1. Increase oral intake of iron and instruct client in food choices that are high in iron (see Box 11-2 in Chapter 11 for iron-rich foods).
2. Administer iron supplements as prescribed.
3. Intramuscular injections of iron (using Z-track method) or IV administration of iron may be prescribed in severe cases of anemia.
4. Teach clients how to administer the iron supplements.
   a. Take between meals for maximum absorption.
   b. Take with a multivitamin or fruit juice, because vitamin C increases absorption.
   c. Do not take with milk or antacids, because these items decrease absorption.
   d. Instruct the client about the side effects of iron supplements (black stools, constipation, and foul aftertaste).
   e. Liquid iron preparations stains the teeth. Teach the client that liquid iron should be taken through a straw and that the teeth should be brushed after administration.

XXVIII. Vitamin B₁₂ Deficiency Anemia

A. Description
1. A macrocytic anemia that results from an inadequate intake of vitamin B₁₂ or lack of absorption of ingested vitamin B₁₂ from the intestinal tract.
2. Pernicious anemia results from a deficiency of intrinsic factor (normally secreted by the gastric mucosa), necessary for intestinal absorption of vitamin B₁₂; gastric disease or surgery can result in a lack of intrinsic factor.

B. Assessment
1. Severe pallor
2. Fatigue
3. Weight loss
4. Smooth, beefy red tongue
5. Slight jaundice
6. Paresthesias of the hands and feet
7. Disturbances with gait and balance

C. Interventions

1. Increase dietary intake of foods rich in vitamin B$_{12}$ such as citrus fruits, dried beans, green leafy vegetables, liver, nuts, organ meats, and brewer’s yeast if the anemia is a result of a dietary deficiency.

2. Administer vitamin B$_{12}$ injections as prescribed, weekly initially and then monthly for maintenance (lifelong) if the anemia is the result of a deficiency of intrinsic factor or disease or surgery of the ileum.

XXIX. Folate Deficiency Anemia

A. Description

1. A macrocytic anemia in which red blood cells are larger than normal and are oval-shaped rather than round-shaped due to the lack of inadequate intake of folate (vitamin B$_9$).

2. Folic acid is required for DNA synthesis required for red blood cell formation and maturation.

3. Common causes include dietary deficiency; malabsorption syndromes such as Celiac disease, Crohn’s disease, or small bowel resection; medications (such as antiseizure medications) that decrease the absorption of folic acid, a condition (including pregnancy) that increases the requirement of folic acid; chronic alcoholism; and chronic hemodialysis.

B. Assessment

1. Dyspepsia

2. Smooth, beefy red tongue

3. Pallor, fatigue and weakness

4. Tinnitus

5. Tachycardia

C. Interventions

1. Encourage the client to eat foods rich in folic acid, such as green leafy vegetables, meat, liver, fish, legumes, peanuts, orange juice, and avocado.

2. Administer folic acid as prescribed.

XXX. Sickle Cell Anemia: See Chapter 30 for more information regarding sickle cell anemia

XXXI. Thalassemia: See Chapter 30 for more information regarding thalassemia

XXXII. Aplastic Anemia

A. Description

1. Aplastic anemia is a deficiency of circulating erythrocytes and all other formed elements of blood, resulting from the arrested development of cells within the bone marrow.

2. It can be primary (present at birth) or secondary (acquired).
3. Several possible causes exist, including chronic exposure to myelotoxic agents, viruses and infections such as hepatitis, Epstein-Barr virus, autoimmune disorders such as human immunodeficiency virus, and allergic states.
4. The definitive diagnosis is determined by bone marrow aspiration (shows conversion of red bone marrow to fatty bone marrow).
5. Therapeutic management focuses on restoring function to the bone marrow and involves immunosuppressive therapy and bone marrow transplantation (treatment of choice if a suitable donor exists).
6. If the cause is a myelotoxic medication that is being administered for another purpose, the medication may be discontinued to improve bone marrow function.

B. Assessment
1. Pancytopenia (deficiency of erythrocytes, leukocytes, and thrombocytes)
2. Petechiae, purpura, bleeding, pallor, weakness, tachycardia, and fatigue

C. Interventions
1. Prepare the client for bone marrow transplantation if planned.
2. Administer immunosuppressive medications as prescribed; antilymphocyte globulin or antithymocyte globulin may be prescribed to suppress the autoimmune response.
3. Colony-stimulating factors may be prescribed to enhance bone marrow production.
4. Corticosteroids and cyclosporine may be prescribed.
5. Administer blood transfusions if prescribed and monitor for transfusion reactions.

Box 44-1
Common Sites of Metastasis

Bladder Cancer
- Lung
- Bone
- Liver
- Pelvic, retroperitoneal structures
Brain Tumors

  • Retroperitoneal lymph nodes

Box 44-2
Grading and Staging

Grading

1310
Grade I: Cells differ slightly from normal cells and are well differentiated (mild dysplasia).

Grade II: Cells are more abnormal and are moderately differentiated (moderate dysplasia).

Grade III: Cells are very abnormal and are poorly differentiated (severe dysplasia).

Grade IV: Cells are immature (anaplasia) and undifferentiated; cell of origin is difficult to determine.

**Staging**

Stage 0: Carcinoma in situ
Stage I: Tumor limited to the tissue of origin; localized tumor growth
Stage II: Limited local spread
Stage III: Extensive local and regional spread
Stage IV: Distant metastasis

---

**Box 44-3**

**Warning Signs of Cancer—CAUTION**

- Change in bowel or bladder habits
- Any sore that does not heal
- Unusual bleeding or discharge
- Thickening or lump in breast or elsewhere
- Indigestion
- Obvious change in wart or mole
- Nagging cough or hoarseness

Data from WebMD: *Understanding cancer—symptoms.*

---

**Box 44-4**

**Diagnostic Tests**

- Biopsy
- Bone marrow examination (particularly if a hematolymphoid malignancy is suspected)
- Chest radiograph
- Complete blood count (CBC)
- Computed tomography (CT); positron emission tomography (PET)
- Cytological studies (Papanicolaou test)
- Evaluation of serum tumor markers (e.g., carcinoembryonic antigen and alpha-fetoprotein)
- Liver function studies
- Magnetic resonance imaging (MRI)
- Proctoscopic examination (including guaiac test for occult blood)
- Radiographic studies (mammography)
- Radioisotope scanning (liver, brain, bone, lung)
- Tumor markers

**Box 44-5**

**Client Education Guide: Radiation Therapy for Cancer**

- Wash the irradiated area gently each day with warm water alone or with mild soap and water.
- Use the hand rather than a washcloth to wash the area.
- Rinse soap thoroughly from the skin.
- Take care not to remove the markings that indicate exactly where the beam of radiation is to be focused.
- Dry the irradiated area with patting motions rather than rubbing motions; use a clean, soft towel or cloth.
- Use no powders, ointments, lotions, or creams on the skin at the radiation site unless they are prescribed by the radiologist.
- Wear soft clothing over the skin at the radiation site.
- Avoid wearing belts, buckles, straps, or any type of clothing that binds or rubs the skin at the radiation site.
- Avoid exposure of the irradiated area to the sun.
- Avoid heat exposure.

**Box 44-6**

**Care of the Client with a Sealed Radiation Implant**

- Place the client in a private room with a private bath.
- Place a radiation precaution sign on the client’s door.
- Organize nursing tasks to minimize exposure to the radiation source.
- Nursing assignments to a client with a radiation implant should be rotated.
- Limit time to 30 minutes per care provider per shift.
- Wear a dosimeter film badge to measure radiation exposure.
- Lead shielding may be used to reduce exposure to radiation.
- The nurse should never care for more than 1 client with a radiation implant at 1 time.
- Do not allow a pregnant nurse to care for the client.
- Do not allow children younger than 16 years or a pregnant woman to visit the client.
- Limit visitors to 30 minutes per day; visitors should be at least 6 feet from the source.
- Save bed linens and dressings until the source is removed; then dispose of the linens and dressings in the usual manner.
- Other equipment can be removed from the room at any time.

**Box 44-7**

**Classification of Leukemia**

**Acute Lymphocytic Leukemia**

- Mostly lymphoblasts present in bone marrow
- Age of onset is younger than 15 years.

**Acute Myelogenous Leukemia**

- Mostly myeloblasts present in bone marrow
- Age of onset is between 15 and 39 years.

**Chronic Myelogenous Leukemia**

- Mostly granulocytes present in bone marrow
- Age of onset is in the fourth decade.

**Chronic Lymphocytic Leukemia**

- Mostly lymphocytes present in bone marrow
- Age of onset is after 50 years.

**Box 44-8**

**Mouth Care for the Client with Mucositis**
- Inspect the mouth daily.
- Offer complete mouth care before and after every meal and at bedtime.
- Brush the teeth and tongue with a soft-bristled toothbrush or sponges.
- Provide mouth rinses every 12 hours with the prescribed solution.
- Administer topical anesthetic agents to mouth sores as prescribed.
- Avoid the use of alcohol- or glycerin-based mouthwashes or swabs because they are irritating to the mucosa.
- Offer soft foods that are cool to warm in temperature rather than foods that are hard or spicy or cold or hot.

**FIG. 44-1** Testicular self-examination. The best time to perform this examination is right after a shower when your scrotal skin is moist and relaxed, making the testicles easy to feel. First, gently lift each testicle. Each one should feel like an egg, firm but not hard, and smooth with no lumps. Then, using both hands, place your middle fingers on the underside of each testicle and your thumbs on top. Gently roll the testicle between the thumb and fingers to feel for any lumps, swelling, or mass. If you notice any changes from 1 month to the next, notify your primary health care provider.
**Box 44-9**
Premalignant Cancers: Stages of Cervical Intraepithelial Neoplasia

- **Stage I:** Mild dysplasia
- **Stage II:** Moderate dysplasia
- **Stage III:** Severe dysplasia to carcinoma in situ

**Box 44-10**
Treatment for Cervical Cancer

**Nonsurgical**

- Chemotherapy
- Cryosurgery
- External radiation
- Internal radiation implants (intracavitary)
- Laser therapy

**Surgical**

- Conization
- Hysterectomy
- Pelvic exenteration

*Note:* Internal radiation therapy is used for clients for whom surgery is not an option.

**Box 44-11**
Types of Pelvic Exenteration

**Anterior**

- Removal of the uterus, ovaries, fallopian tubes, vagina, bladder, urethra, and pelvic lymph nodes

**Posterior**

- Removal of the uterus, ovaries, fallopian tubes, descending colon, rectum, and anal canal

Breast self-examination and client instructions. 1, While in the shower or bath, when the skin is slippery with soap and water, examine your breasts. Use the pads of your second, third, and fourth fingers to press every part of the breast firmly. Use your right hand to examine your left breast, and use your left hand to examine your right breast. Using the pads of the fingers on your left hand, examine the entire right breast using small circular motions in a spiral or up-and-down motion so that the entire breast area is examined. Repeat the procedure using your right hand to examine your left breast. Repeat the pattern of palpation under the arm. Check for any lump, hard knot, or thickening of the tissue. 2, Look at your breasts in a mirror. Stand with your arms at your side. 3, Raise your arms overhead and check for any changes in the shape of your breasts, dimpling of the skin, or any changes in the nipple. 4, Next, place your hands on your hips and press down firmly, tightening the pectoral muscles. Observe for asymmetry or changes, keeping in mind that your breasts probably do not match exactly. 5, While lying down, feel your
breasts as described in step 1. When examining your right breast, place a folded towel under your right shoulder and put your right hand behind your head. Repeat the procedure while examining your left breast. Mark your calendar that you have completed your breast self-examination; note any changes or unique characteristics you want to check with your primary health care provider.

**Box 44-12**

Surgical Breast Procedures

**Lumpectomy**

- Tumor is excised and removed.
- Lymph node dissection may also be performed.

**Simple Mastectomy**

- Breast tissue and the nipple are removed.
- Lymph nodes are usually left intact.

**Modified Radical Mastectomy**

- Breast tissue, nipple, and lymph nodes are removed.
- Muscles are left intact.
**Box 44-13**

**Client Instructions Following Mastectomy**

- Avoid overuse of the arm during the first few months.
- To prevent lymphedema, keep the affected arm elevated; consultation with lymphedema specialist may be prescribed.
- Provide incision care with an emollient as prescribed, to soften and prevent wound contracture.
- Encourage use of support groups.
- Encourage the client to perform breast self-examination on the remaining breast and surgical site once healed.
- Protect the affected hand and arm.
- Avoid strong sunlight on the affected arm.
- Do not let the affected arm hang dependent.
- Do not carry a pocketbook or anything heavy over the affected arm.
- Avoid trauma, cuts, bruises, or burns to the affected side.
- Avoid wearing constricting clothing or jewelry on the affected side.
- Wear gloves when gardening.
- Use thick oven mitts when cooking.
- Use a thimble when sewing.
- Apply hand cream several times daily.
- Use cream cuticle remover.
- Call the primary health care provider if signs of inflammation occur in the affected arm.
- Wear a MedicAlert bracelet stating which arm is at risk for lymphedema.

**Box 44-14**

**Surgical Interventions for Gastric Cancer**

**Subtotal Gastrectomy**

**Billroth I**

- Also called gastroduodenostomy
- Partial gastrectomy, with remaining segment anastomosed to the duodenum
Billroth II

- Also called gastrojejunostomy
- Partial gastrectomy, with remaining segment anastomosed to the jejunum

Total Gastrectomy

- Also called esophagojejunostomy
- Removal of the stomach, with attachment of the esophagus to the jejunum or duodenum

FIG. 44-4 Whipple procedure, or radical pancreaticoduodenectomy.
Box 44-15

Stoma Care Following Laryngectomy

- Protect the neck from injury.
- Instruct the client in how to clean the incision and provide stoma care.
- Instruct the client to wear a stoma guard to shield the stoma.
- Demonstrate ways to prevent debris from entering the stoma.
- Advise the client to wear loose-fitting, high-collared clothing to cover the stoma.
- Avoid swimming, showering, and using aerosol sprays.
- Teach the client clean suctioning technique.
- Advise the client to increase humidity in the home.
- Increase fluid intake to 3000 mL/day as prescribed.
- Avoid exposure to persons with infections.
- Alternate rest periods with activity.
- Instruct the client in range-of-motion exercises for the arms, shoulders, and neck as prescribed.
- Advise the client to wear a MedicAlert bracelet.
Box 44-16

Speech Rehabilitation Following Laryngectomy

Esophageal Speech

▪ The client produces esophageal speech by “burping” the air swallowed.
▪ The voice produced is monotone, cannot be raised or lowered, and carries no pitch.
▪ The client must have adequate hearing because his or her mouth shapes words as they are heard.

Mechanical Devices

▪ One device, the electrolarynx, is placed against the side of the neck; the air inside the neck and pharynx is vibrated, and the client articulates.
▪ Another device consists of a plastic tube that is placed inside the client’s mouth and vibrates on articulation.

Tracheoesophageal Fistula

▪ A fistula is created surgically between the trachea and the esophagus, with eventual placement of a prosthesis to produce speech.
▪ The prosthesis provides the client with a means to divert air from the trachea into the esophagus, and out of the mouth.
▪ Lip and tongue movement produce the speech.

Box 44-17

Continuous Bladder Irrigation (CBI)

Description

▪ A 3-way (lumen) irrigation is used to decrease bleeding and to keep the bladder free from clots—1 lumen is for inflating the balloon (30 mL); 1 lumen is for instillation (inflow); 1 lumen is for outflow.

Interventions

▪ Maintain traction on the catheter, if applied and prescribed, to prevent bleeding by pulling the catheter taut and taping it to the abdomen or thigh.
▪ Instruct the client to keep the leg straight if traction is applied to the catheter and taped to the thigh.
• Catheter traction is not released without the surgeon’s prescription; it usually is released after any bright red drainage has diminished.

• Use only sterile bladder irrigation solution or prescribed solution to prevent water intoxication.

• Run the solution at a rate, as prescribed, to keep the urine pink. Run the solution rapidly if bright red drainage or clots are present; monitor output closely. Run the solution at about 40 drops (gtt)/minute when the bright red drainage clears.

• If the urinary catheter becomes obstructed, turn off the CBI and irrigate the catheter with 30 to 50 mL of normal saline, if prescribed; notify the surgeon if obstruction does not resolve.

• Discontinue CBI and the urinary catheter as prescribed, usually 24 to 48 hours after surgery.

• Monitor for continence and urinary retention when the catheter is removed. Inform the client that some burning, frequency, and dribbling may occur following catheter removal.

• Inform the client that he should be voiding 150 to 200 mL of clear yellow urine every 3 to 4 hours by 3 days after surgery.

• Inform the client that he may pass small clots and tissue debris for several days.

• Teach the client to avoid heavy lifting, stressful exercise, driving, the Valsalva maneuver, and sexual intercourse for 2 to 6 weeks to prevent strain, and to call the surgeon if bleeding occurs or if there is a decrease in urinary stream.

• Instruct the client to drink 2400 to 3000 mL of fluid each day, preferably before 8 p.m., to avoid nocturia.

• Instruct the client to avoid alcohol, caffeinated beverages, and spicy foods and overstimulation of the bladder.

• Instruct the client that if the urine becomes bloody, to rest and increase fluid intake and, if the bleeding does not subside, to notify the surgeon.
Urinary diversion procedures used in the treatment of bladder cancer.

**FIG. 44-6** Urinary diversion procedures used in the treatment of bladder cancer.

**Box 44-18**

**Urinary Stoma Care**

- Instruct the client to change the appliance in the morning, when urinary production is slowest.
- Collect equipment, remove collection bag, and use water or commercial solvent to loosen adhesive.
Hold a rolled gauze pad against the stoma to collect and absorb urine during the procedure.

- Cleanse the skin around the stoma and under the drainage bag with mild nonresidue soap and water.
- Inspect the skin for excoriation, and instruct the client to prevent urine from coming into contact with the skin.
- After the skin is dry, apply skin adhesive around the appliance.
- Instruct the client to cut the stoma opening of the skin barrier just large enough to fit over the stoma (no more than 3 mm larger than the stoma).
- Instruct the client that the stoma will begin to shrink, requiring a smaller stoma opening on the skin barrier.
- Apply the skin barrier before attaching the pouch or face plate.
- Place the appliance over the stoma and secure in place.
- Encourage self-care; teach the client to use a mirror.
- Instruct the client that the pouch may be drained by a bedside bag or leg bag, especially at night.
- Instruct the client to empty the urinary collection bag when it is one-third full to prevent pulling of the appliance and leakage.
- Instruct the client to check the appliance seal if perspiring occurs.
- Instruct the client to leave the urinary pouch in place as long as it is not leaking and to change it every 5 to 7 days.
- During appliance changes, leave the skin open to air for as long as possible.
- Use a non–karaya product, because urine erodes karaya.
- To control odor, instruct the client to drink adequate fluids, wash the appliance thoroughly with soap and lukewarm water, and soak the collection pouch in dilute white vinegar for 20 to 30 minutes; a special deodorant tablet can also be placed into the pouch while it is being worn.
- Instruct the client who takes baths to keep the level of the water below the stoma and to avoid oily soaps.
- If the client plans to shower, instruct the client to direct the flow of water away from the stoma.

**Box 44-19**

**Self-Irrigation and Catheterization of Stoma**

**Irrigation**

- Instruct the client to wash hands and use clean technique.
- Instruct the client to use a catheter and syringe, instill 60 mL of normal saline or water into the reservoir, and aspirate gently or allow to drain.
- Instruct the client to irrigate until the drainage remains free of mucus but to be careful not to overirrigate.
Catheterization

- Instruct the client to wash hands and use clean technique.
- Initially, instruct the client to insert a catheter every 2 to 3 hours to drain the reservoir; during each week thereafter, increase the interval by 1 hour until catheterization is done every 4 to 6 hours.
- Lubricate the catheter well with water-soluble lubricant, and instruct the client never to force the catheter into the reservoir.
- If resistance is met, instruct the client to pause, rotate the catheter, and apply gentle pressure to insert.
- Instruct the client to notify the surgeon if the client is unable to insert the catheter.
- When urine has stopped, instruct the client to take several deep breaths and move the catheter in and out 2 to 3 inches (5 to 7.5 cm) to ensure that the pouch is empty.
- Instruct the client to withdraw the catheter slowly and pinch the catheter when withdrawn so that it does not leak urine.
- Instruct the client to carry catheterization supplies with him or her.
Practice Questions

443. The nurse is reviewing the laboratory results of a client diagnosed with multiple myeloma. Which would the nurse expect to note specifically in this disorder?
   1. Increased calcium level
   2. Increased white blood cells
   3. Decreased blood urea nitrogen level
   4. Decreased number of plasma cells in the bone marrow

444. The nurse is creating a plan of care for the client with multiple myeloma and includes which priority intervention in the plan?
   1. Encouraging fluids
   2. Providing frequent oral care
   3. Coughing and deep breathing
   4. Monitoring the red blood cell count

445. When caring for a client with an internal radiation implant, the nurse should observe which principles? Select all that apply.
   1. Limiting the time with the client to 1 hour per shift.
   2. Keeping pregnant women out of the client’s room.
   3. Placing the client in a private room with a private bath.
   4. Wearing a lead shield when providing direct client care.
   5. Removing the dosimeter film badge when entering the client’s room.
   6. Allowing individuals younger than 16 years old in the room as long as they are 6 feet away from the client.

446. While giving care to a client with an internal cervical radiation implant, the nurse finds the implant in the bed. The nurse should take which initial action?
   1. Call the primary health care provider (PHCP).
   2. Reinsert the implant into the vagina.
   3. Pick up the implant with gloved hands and flush it down the toilet.
   4. Pick up the implant with long-handled forceps and place it in a lead container.

447. The nurse should plan to implement which intervention in the care of a client experiencing neutropenia as a result of chemotherapy?
   1. Restrict all visitors.
   2. Restrict fluid intake.
   3. Teach the client and family about the need for hand hygiene.
   4. Insert an indwelling urinary catheter to prevent skin breakdown.

448. The home health care nurse is caring for a client with cancer who is complaining of acute pain. The most appropriate determination of the client’s pain should include which assessment?
   1. The client’s pain rating
   2. Nonverbal cues from the client
   3. The nurse’s impression of the client’s pain
4. Pain relief after appropriate nursing intervention

449. The nurse is caring for a client who is postoperative following a pelvic exenteration, and the surgeon changes the client’s diet from NPO (nothing by mouth) status to clear liquids. The nurse should check which priority item before administering the diet?

1. Bowel sounds
2. Ability to ambulate
3. Incision appearance
4. Urine specific gravity

450. A client is admitted to the hospital with a suspected diagnosis of Hodgkin’s disease. Which assessment finding would the nurse expect to note specifically in the client?

1. Fatigue
2. Weakness
3. Weight gain
4. Enlarged lymph nodes

451. During the admission assessment of a client with advanced ovarian cancer, the nurse recognizes which manifestation as typical of the disease?

1. Diarrhea
2. Hypermenorrhea
3. Abnormal bleeding
4. Abdominal distention

452. The nurse is caring for a client with lung cancer and bone metastasis. What signs and symptoms would the nurse recognize as indications of a possible oncological emergency? Select all that apply.

1. Facial edema in the morning
2. Weight loss of 20 lb (9 kg) in 1 month
3. Serum calcium level of 12 mg/dL (3.0 mmol/L)
4. Serum sodium level of 136 mg/dL (136 mmol/L)
5. Serum potassium level of 3.4 mg/dL (3.4 mmol/L)
6. Numbness and tingling of the lower extremities

453. A client who has been receiving radiation therapy for bladder cancer tells the nurse that it feels as if she is voiding through the vagina. The nurse interprets that the client may be experiencing which condition?

1. Rupture of the bladder
2. The development of a vesicovaginal fistula
3. Extreme stress caused by the diagnosis of cancer
4. Altered perineal sensation as a side effect of radiation therapy

454. The nurse is instructing a client to perform a testicular self-examination (TSE). The nurse should provide the client with which information about the procedure?

1. To examine the testicles while lying down
2. That the best time for the examination is after a shower
3. To gently feel the testicle with one finger to feel for a growth
4. That TSEs should be done at least every 6 months

455. The nurse is conducting a history and monitoring laboratory values on a client with multiple myeloma. What assessment findings should the nurse expect to note? Select all that apply.
1. Pathological fracture
2. Urinalysis positive for Bence Jones protein
3. Hemoglobin level of 15.5 g/dL (155 mmol/L)
4. Calcium level of 8.6 mg/dL (2.15 mmol/L)
5. Serum creatinine level of 2.0 mg/dL (176.6 mcmol/L)

456. A gastrectomy is performed on a client with gastric cancer. In the immediate postoperative period, the nurse notes bloody drainage from the nasogastric tube. The nurse should take which **most appropriate** action?
   1. Measure abdominal girth.
   2. Irrigate the nasogastric tube.
   3. Continue to monitor the drainage.
   4. Notify the primary health care provider (PHCP).

457. The nurse is teaching a client about the risk factors associated with colorectal cancer. The nurse determines that **further teaching is necessary** related to colorectal cancer if the client identifies which item as an associated risk factor?
   1. Age younger than 50 years
   2. History of colorectal polyps
   3. Family history of colorectal cancer
   4. Chronic inflammatory bowel disease

458. The nurse is assessing the perineal wound in a client who has returned from the operating room following an abdominal perineal resection and notes serosanguineous drainage from the wound. Which nursing intervention is **most appropriate**?
   1. Clamp the surgical drain.
   2. Change the dressing as prescribed.
   3. Notify the surgeon.
   4. Remove and replace the perineal packing.

459. The nurse is assessing the colostomy of a client who has had an abdominal perineal resection for a bowel tumor. Which assessment finding indicates that the colostomy is beginning to function?
   1. The passage of flatus
   2. Absent bowel sounds
   3. The client’s ability to tolerate food
   4. Bloody drainage from the colostomy

460. The nurse is reviewing the history of a client with bladder cancer. The nurse expects to note documentation of which **most common** sign or symptom of this type of cancer?
   1. Dysuria
   2. Hematuria
   3. Urgency on urination
   4. Frequency of urination

461. The nurse is assessing a client who has a new ureterostomy. Which statement by the client indicates the **need for more education** about urinary stoma care?
1. “I change my pouch every week.”
2. “I change the appliance in the morning.”
3. “I empty the urinary collection bag when it is two-thirds full.”
4. “When I’m in the shower I direct the flow of water away from my stoma.”

462. A client with carcinoma of the lung develops syndrome of inappropriate antidiuretic hormone (SIADH) as a complication of the cancer. The nurse anticipates that the primary health care provider will request which prescriptions? Select all that apply.
   1. Radiation
   2. Chemotherapy
   3. Increased fluid intake
   4. Decreased oral sodium intake
   5. Serum sodium level determination
   6. Medication that is antagonistic to antidiuretic hormone

463. The nurse is monitoring a client for signs and symptoms related to superior vena cava syndrome. Which is an early sign of this oncological emergency?
   1. Cyanosis
   2. Arm edema
   3. Periorbital edema
   4. Mental status changes

464. The nurse manager is teaching the nursing staff about signs and symptoms related to hypercalcemia in a client with metastatic prostate cancer and tells the staff that which is a late sign or symptom of this oncological emergency?
   1. Headache
   2. Dysphagia
   3. Constipation
   4. Electrocardiographic changes

465. As part of chemotherapy education, the nurse teaches a female client about the risk for bleeding and self-care during the period of greatest bone marrow suppression (the nadir). The nurse understands that further teaching is needed if the client makes which statement?
   1. “I should avoid blowing my nose.”
   2. “I may need a platelet transfusion if my platelet count is too low.”
   3. “I’m going to take aspirin for my headache as soon as I get home.”
   4. “I will count the number of pads and tampons I use when menstruating.”

466. The community health nurse is instructing a group of young female clients about breast self-examination. The nurse should instruct the clients to perform the examination at which time?
   1. At the onset of menstruation
   2. Every month during ovulation
   3. Weekly at the same time of day
   4. One week after menstruation begins

467. A client is diagnosed as having a intestinal tumor. The nurse should monitor the client for which complications of this type of tumor? Select all that apply.
   1. Flatulence
2. Peritonitis
3. Hemorrhage
4. Fistula formation
5. Bowel perforation
6. Lactose intolerance

468. The nurse is caring for a client following a mastectomy. Which nursing intervention would assist in preventing lymphedema of the affected arm?
1. Placing cool compresses on the affected arm
2. Elevating the affected arm on a pillow above heart level
3. Avoiding arm exercises in the immediate postoperative period
4. Maintaining an intravenous site below the antecubital area on the affected side

469. The nurse is providing dietary teaching for a client with a diagnosis of chronic gastritis. The nurse instructs the client to include which foods rich in vitamin B\textsubscript{12} in the diet? Select all that apply.

- [ ] 1. Nuts
- [ ] 2. Corn
- [ ] 3. Liver
- [ ] 4. Apples
- [ ] 5. Lentils
- [ ] 6. Bananas

470. The nurse is instructing a client with iron deficiency anemia regarding the administration of a liquid oral iron supplement. Which instruction should the nurse tell the client?
1. Administer the iron at mealtimes.
2. Administer the iron through a straw.
3. Mix the iron with cereal to administer.
4. Add the iron to apple juice for easy administration.

471. Laboratory studies are performed for a client suspected to have iron deficiency anemia. The nurse reviews the laboratory results, knowing that which result indicates this type of anemia?
1. Elevated hemoglobin level
2. Decreased reticulocyte count
3. Elevated red blood cell count
4. Red blood cells that are microcytic and hypochromic

**Answers**

443. **Answer:** 1

**Rationale:** Findings indicative of multiple myeloma are an increased number of plasma cells in the bone marrow, anemia, hypercalcemia caused by the release of calcium from the deteriorating bone tissue, and an elevated blood urea nitrogen.
level. An increased white blood cell count may or may not be present and is not related specifically to multiple myeloma.

**Test-Taking Strategy:** Focus on the subject, laboratory findings in multiple myeloma. Noting the name of the disorder and recalling the pathophysiology of the disease and that proliferation of plasma cells in the bone occurs will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Oncology  
**Health Problem:** Adult Health: Cancer: Multiple Myeloma  
**Priority Concepts:** Cellular Regulation; Clinical Judgment  

444. **Answer:** 1

**Rationale:** Hypercalcemia caused by bone destruction is a priority concern in the client with multiple myeloma. The nurse should administer fluids in adequate amounts to maintain a urine output of 1.5 to 2 L/day; this requires about 3 L of fluid intake per day. The fluid is needed not only to dilute the calcium overload but also to prevent protein from precipitating in the renal tubules. Options 2, 3, and 4 may be components of the plan of care but are not the priority in this client.

**Test-Taking Strategy:** Note the strategic word, priority. Recalling the pathophysiology of this disorder and that hypercalcemia can occur will direct you to the correct option.

**Level of Cognitive Ability:** Creating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Adult Health: Oncology  
**Health Problem:** Adult Health: Cancer: Multiple Myeloma  
**Priority Concepts:** Cellular Regulation; Clinical Judgment  
**Reference:** Lewis et al. (2017), p. 646.

445. **Answer:** 2, 3, 4

**Rationale:** The time that the nurse spends in the room of a client with an internal radiation implant is 30 minutes per shift. The client must be placed in a private room with a private bath. Lead shielding can be used to reduce the transmission of radiation. The dosimeter film badge must be worn when in the client’s room. Children younger than 16 years of age and pregnant women are not allowed in the client’s room.

**Test-Taking Strategy:** Focus on the subject, radiation precautions. Recalling the time frame related to exposure to the client will assist in eliminating option 1. From the remaining options, select the correct options because of the possible risks associated with exposure to radiation.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Safe and Effective Care Environment
446. Answer: 4

Rationale: In the event that a radiation source becomes dislodged, the nurse would first encourage the client to lie still until the radioactive source has been placed in a safe, closed container. The nurse would use long-handled forceps to place the source in the lead container that should be in the client’s room. The nurse should then call the radiation oncologist and document the event and the actions taken. It is not within the scope of nursing practice to insert a radiation implant.

Test-Taking Strategy: Note the strategic word, initial. The initial action would be to prevent self-contamination from radiation exposure. This will direct you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Safe and Effective Care Environment
Integrated Process: Nursing Process—Implementation
Content Area: Foundations of Care: Safety
Health Problem: N/A
Priority Concepts: Cellular Regulation; Safety

447. Answer: 3

Rationale: In the neutropenic client, meticulous hand hygiene education is implemented for the client, family, visitors, and staff. Not all visitors are restricted, but the client is protected from persons with known infections. Fluids should be encouraged. Invasive measures such as an indwelling urinary catheter should be avoided to prevent infections.

Test-Taking Strategy: Eliminate option 1 because of the closed-ended word all. Next, eliminate option 2 because it is not reasonable to restrict fluids in a client receiving chemotherapy who is at risk for fluid and electrolyte imbalances. Eliminate option 4 because of the risk of infection that exists with this measure.

Level of Cognitive Ability: Applying
Client Needs: Safe and Effective Care Environment
Integrated Process: Nursing Process—Implementation
Content Area: Foundations of Care: Safety
Health Problem: N/A
Priority Concepts: Caregiving; Infection

448. Answer: 1

Rationale: The client’s self-report is a critical component of pain assessment. The
nurse should ask the client to describe the pain and listen carefully to the words the client uses to describe the pain. Nonverbal cues from the client are important but are not the most appropriate pain assessment measure. The nurse’s impression of the client’s pain is not appropriate in determining the client’s level of pain. Assessing pain relief is an important measure, but this option is not related to the subject of the question.

**Test-Taking Strategy:** Note the strategic words, *most appropriate*. Eliminate option 3 because the nurse is not the client of the question. From the remaining options, the subjective data from the client will provide the most accurate description of the pain.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Caring

**Content Area:** Foundations of Care: Vital Signs

**Health Problem:** N/A

**Priority Concepts:** Caregiving; Pain

**Reference:** Lewis et al. (2017), pp. 107-108.

449. **Answer:** 1

**Rationale:** The client is kept NPO until peristalsis returns, usually in 4 to 6 days. When signs of bowel function return, clear fluids are given to the client. If no distention occurs, the diet is advanced as tolerated. The most important assessment is to assess bowel sounds before feeding the client. Options 2, 3, and 4 are unrelated to the data in the question.

**Test-Taking Strategy:** Note the strategic word, *priority*, and the words *NPO status to clear liquids* in the question. The correct option is the only one that relates to gastrointestinal function.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Foundations of Care: Perioperative Care

**Health Problem:** N/A

**Priority Concepts:** Clinical Judgment; Nutrition

**Reference:** Lewis et al. (2017), pp. 342, 1261.

450. **Answer:** 4

**Rationale:** Hodgkin’s disease is a chronic progressive neoplastic disorder of lymphoid tissue characterized by the painless enlargement of lymph nodes with progression to extralymphatic sites, such as the spleen and liver. Weight loss is most likely to be noted. Fatigue and weakness may occur but are not related significantly to the disease.

**Test-Taking Strategy:** Options 1 and 2 are comparable or alike and are rather vague symptoms that can occur in many disorders. Option 3 can be eliminated because, in such a disorder, weight loss is most likely to occur. Also, recalling that Hodgkin’s disease affects the lymph nodes will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Oncology
Health Problem: Adult Health: Cancer: Lymphoma: Hodgkin’s and non-Hodgkin’s
Priority Concepts: Cellular Regulation; Clinical Judgment

451. Answer: 4

Rationale: Clinical manifestations of ovarian cancer include abdominal distention, urinary frequency and urgency, pleural effusion, malnutrition, pain from pressure caused by the growing tumor and the effects of urinary or bowel obstruction, constipation, ascites with dyspnea, and ultimately general severe pain. Abnormal bleeding, often resulting in hypermenorrhea, is associated with uterine cancer.

Test-Taking Strategy: Eliminate options 2 and 3 first because they are comparable or alike. From the remaining options, consider the anatomical location of the cancer. This will assist in directing you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Oncology
Health Problem: Adult Health: Cancer: Cervical/Uterine/Ovarian
Priority Concepts: Cellular Regulation; Clinical Judgment

452. Answer: 1, 3, 6

Rationale: Oncological emergencies include sepsis, disseminated intravascular coagulation, syndrome of inappropriate antidiuretic hormone, spinal cord compression, hypercalcemia, superior vena cava syndrome, and tumor lysis syndrome. Blockage of blood flow to the venous system of the head resulting in facial edema is a sign of superior vena cava syndrome. A serum calcium level of 12 mg/dL (3.0 mmol/L) indicates hypercalcemia. Numbness and tingling of the lower extremities could be a sign of spinal cord compression. Mild hypokalemia and weight loss are not oncological emergencies. A sodium level of 136 mg/dL (136 mmol/L) is a normal level.

Test-Taking Strategy: Note the subject, an oncological emergency. Recalling the signs and symptoms of oncological emergencies will help you identify the correct options. Also, recalling the normal calcium, potassium, and sodium levels will direct you to the correct options.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Oncology
Health Problem: Adult Health: Cancer: Laryngeal and Lung
Priority Concepts: Cellular Regulation; Clinical Judgment
453. **Answer:** 2

**Rationale:** A vesicovaginal fistula is a genital fistula that occurs between the bladder and vagina. The fistula is an abnormal opening between these two body parts, and if this occurs, the client may experience drainage of urine through the vagina. The client’s complaint is not associated with options 1, 3, or 4.

**Test-Taking Strategy:** Focus on the **subject**, a complication of bladder cancer. Noting the words *voiding through the vagina* should direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Analysis

**Content Area:** Adult Health: Oncology

**Health Problem:** Adult Health: Cancer: Bladder and Kidney

**Reference:** Lewis et al. (2017), p. 1263.

---

454. **Answer:** 2

**Rationale:** The TSE is recommended monthly after a warm bath or shower when the scrotal skin is relaxed. The client should stand to examine the testicles. Using both hands, with fingers under the scrotum and thumbs on top, the client should gently roll the testicles, feeling for any lumps.

**Test-Taking Strategy:** Focus on the **subject**, the procedure for performing TSE. Eliminate option 4 first because of the words *6 months*. Next, eliminate option 3 because of the word *one*. From the remaining options, eliminate option 1 by trying to visualize the process of the self-examination.

**Level of Cognitive Ability:** Applying

**Client Needs:** Health Promotion and Maintenance

**Integrated Process:** Teaching and Learning

**Content Area:** Health Assessment/Physical Exam: Testicles

**Health Problem:** Adult Health: Cancer: Testicular

**Priority Concepts:** Clinical Judgment; Health Promotion

---

455. **Answer:** 1, 2, 5

**Rationale:** Multiple myeloma is a B cell neoplastic condition characterized by abnormal malignant proliferation of plasma cells and the accumulation of mature plasma cells in the bone marrow. The client with multiple myeloma may experience pathological fractures, hypercalcemia, anemia, recurrent infections, and renal failure. In addition, Bence Jones proteinuria is a finding. A serum calcium level of 8.6 mg/dL (2.15 mmol/L) and a hemoglobin level of 15.5 g/dL (155 mmol/L) are normal values. A serum creatinine level of 2.0 mg/dL (176.6 mcmol/L) is elevated indicating a renal problem.

**Test-Taking Strategy:** Focus on the **subject**, characteristics of multiple myeloma.
Think about the pathophysiology of the disorder and analyze the values given to direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Oncology  
**Health Problem:** Adult Health: Cancer: Multiple Myeloma  
**Priority Concepts:** Cellular Regulation; Client Education  

456. **Answer:** 3

**Rationale:** Following gastrectomy, drainage from the nasogastric tube is normally bloody for 24 hours postoperatively, changes to brown-tinged, and is then yellow or clear. Because bloody drainage is expected in the immediate postoperative period, the nurse should continue to monitor the drainage. The nurse does not need to notify the PHCP (surgeon) at this time. Abdominal girth is measured to detect the development of distention. Following gastrectomy, a nasogastric tube should not be irrigated unless there are specific surgeon prescriptions to do so.

**Test-Taking Strategy:** Note the **strategic words**, most appropriate, and focus on the **subject**, the immediate postoperative period. This should direct you to the correct option. Remember that drainage from the nasogastric tube is normally bloody for 24 hours postoperatively, changes to brown-tinged, and then to yellow or clear.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Foundations of Care: Perioperative Care  
**Health Problem:** Adult Health: Cancer: Esophageal/Gastric/Intestinal  
**Priority Concepts:** Cellular Regulation; Clinical Judgment  

457. **Answer:** 1

**Rationale:** Colorectal cancer risk factors include age older than 50 years, a family history of the disease, colorectal polyps, and chronic inflammatory bowel disease.

**Test-Taking Strategy:** Note the **strategic words**, further teaching is necessary. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Noting the words younger than in option 1 will direct you to this option.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Health Promotion and Maintenance  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Oncology  
**Health Problem:** Adult Health: Cancer: Esophageal/Gastric/Intestinal  
**Priority Concepts:** Client Education; Health Promotion  
**Reference:** Lewis et al. (2017), p. 954.
Rationale: Immediately after surgery, profuse serosanguineous drainage from the perineal wound is expected. Therefore, the nurse should change the dressing as prescribed. A surgical drain should not be clamped, because this action will cause the accumulation of drainage within the tissue. The nurse does not need to notify the surgeon at this time. Drains and packing are removed gradually over a period of 5 to 7 days as prescribed. The nurse should not remove the perineal packing.

Test-Taking Strategy: Note the strategic words, most appropriate. Eliminate options 1 and 4, knowing that these are inappropriate interventions. Recalling that serosanguineous drainage is expected following this type of surgery will assist in directing you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Adult Health: Oncology
Health Problem: Adult Health: Cancer: Esophageal/Gastric/Intestinal
Priority Concepts: Clinical Judgment; Tissue Integrity

Rationale: Following abdominal perineal resection, the nurse would expect the colostomy to begin to function within 72 hours after surgery, although it may take up to 5 days. The nurse should assess for a return of peristalsis, listen for bowel sounds, and check for the passage of flatus. Absent bowel sounds would not indicate the return of peristalsis. The client would remain NPO (nothing by mouth) until bowel sounds return and the colostomy is functioning. Bloody drainage is not expected from a colostomy.

Test-Taking Strategy: Focus on the subject, the colostomy beginning to function. This should assist in eliminating option 2. Knowledge of general postoperative measures will assist in eliminating option 3. Focus on the subject to assist in eliminating option 4 as a correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Foundations of Care: Perioperative Care
Health Problem: Adult Health: Cancer: Esophageal/Gastric/Intestinal
Priority Concepts: Clinical Judgment; Elimination

Rationale: The most common sign in clients with cancer of the bladder is hematuria. The client also may experience irritative voiding symptoms such as frequency, urgency, and dysuria, and these symptoms often are associated with carcinoma in situ. Dysuria, urgency, and frequency of urination are also symptoms
of a bladder infection.

**Test-Taking Strategy:** Focus on the subject, bladder cancer, and note the strategic word, *most*. Options 1, 3, and 4 are symptoms that are associated most often with bladder infection.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Oncology  
**Health Problem:** Adult Health: Cancer: Bladder and Kidney  
**Priority Concepts:** Cellular Regulation; Elimination  
**Reference:** Lewis et al. (2017), pp. 1053-1054.

461. **Answer:** 3

**Rationale:** The urinary collection bag should be changed when it is one-third full to prevent pulling of the appliance and leakage. The remaining options identify correct statements about the care of a urinary stoma.

**Test-Taking Strategy:** Note the strategic words, *need for more education*, and eliminate the options that indicate client understanding. Noting the words *two-thirds full* will assist in directing you to the correct option.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Oncology  
**Health Problem:** Adult Health: Cancer: Bladder and Kidney  
**Priority Concepts:** Client Education; Elimination  

462. **Answer:** 1, 2, 5, 6

**Rationale:** Cancer is a common cause of SIADH. In SIADH, excessive amounts of water are reabsorbed by the kidney and put into the systemic circulation. The increased water causes hyponatremia (decreased serum sodium levels) and some degree of fluid retention. The syndrome is managed by treating the condition and cause and usually includes fluid restriction, increased sodium intake, and medication with a mechanism of action that is antagonistic to antidiuretic hormone. Sodium levels are monitored closely because hypernatremia can develop suddenly as a result of treatment. The immediate institution of appropriate cancer therapy, usually radiation or chemotherapy, can cause tumor regression so that antidiuretic hormone synthesis and release processes return to normal.

**Test-Taking Strategy:** Focus on the subject, treatment for SIADH, and recall that in SIADH excessive amounts of water are reabsorbed by the kidney and put into the systemic circulation. This will assist in answering this question.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Analysis  
**Content Area:** Adult Health: Oncology
**Health Problem:** Adult Health: Cancer: Laryngeal and Lung  
**Priority Concepts:** Cellular Regulation; Clinical Judgment  

463. **Answer:** 3

**Rationale:** Superior vena cava syndrome occurs when the superior vena cava is compressed or obstructed by tumor growth. Early signs and symptoms generally occur in the morning and include edema of the face, especially around the eyes, and client complaints of tightness of a shirt or blouse collar. As the compression worsens, the client experiences edema of the hands and arms. Cyanosis and mental status changes are late signs.

**Test-Taking Strategy:** Note the *strategic word*, *early*. Think about the pathophysiology associated with this disorder and focus on the strategic word to assist in eliminating options 1, 2, and 4.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Oncology  
**Health Problem:** N/A  
**Priority Concepts:** Cellular Regulation; Clinical Judgment  

464. **Answer:** 4

**Rationale:** Hypercalcemia is a manifestation of bone metastasis in late-stage cancer. Headache and dysphagia are not associated with hypercalcemia. Constipation may occur early in the process. Electrocardiogram changes include shortened ST segment and a widened T wave.

**Test-Taking Strategy:** Note the *strategic word*, *late*. Focus on the name of the oncological emergency, *hypercalcemia*, to direct you to the correct option. Eliminate options 1 and 2 because they are not signs of hypercalcemia. Eliminate option 3 because it is an early sign of hypercalcemia.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Oncology  
**Health Problem:** Adult Health: Cancer: Prostate  
**Priority Concepts:** Cellular Regulation; Fluids and Electrolytes  

465. **Answer:** 3

**Rationale:** During the period of greatest bone marrow suppression (the nadir), the platelet count may be low, less than 20,000 cells mm$^3$ (20.0 × 10$^9$/L). The correct option describes an incorrect statement by the client. Aspirin and nonsteroidal antiinflammatory drugs and products that contain aspirin should be avoided.
because of their antiplatelet activity. Options 1, 2, and 4 are correct statements by the client to prevent and monitor bleeding.

*Test-Taking Strategy:* Note the **strategic words**, *further teaching is needed*. Recalling the effects of bone marrow suppression will direct you to the correct option.

*Level of Cognitive Ability:* Evaluating

*Client Needs:* Physiological Integrity

*Integrated Process:* Teaching and Learning

*Content Area:* Adult Health: Oncology

*Health Problem:* Adult Health: Hematological: Bleeding/Clotting Disorders

*Priority Concepts:* Cellular Regulation; Clinical Judgment

466. **Answer:** 4

*Rationale:* The breast self-examination should be performed regularly, 7 days after the onset of the menstrual period. Performing the examination weekly is not recommended. At the onset of menstruation and during ovulation, hormonal changes occur that may alter breast tissue.

*Test-Taking Strategy:* Option 3 can be eliminated easily because of the word *weekly*. Eliminate options 1 and 2 next because they are comparable or alike in the similarity that exists regarding the hormonal changes that occur during these times.

*Level of Cognitive Ability:* Applying

*Client Needs:* Health Promotion and Maintenance

*Integrated Process:* Teaching and Learning

*Content Area:* Health Assessment/Physical Exam: Breasts

*Health Problem:* Adult Health: Cancer: Breast

*Priority Concepts:* Client Education; Health Promotion

467. **Answer:** 2, 3, 4, 5

*Rationale:* Complications of intestinal tumors include bowel perforation, which can result in hemorrhage and peritonitis. Other complications include bowel obstruction and fistula formation. Flatulence can occur but is not a complication; lactose intolerance also is not a complication of intestinal tumor.

*Test-Taking Strategy:* Focus on the subject, complications of an intestinal tumor. Think about the location and pathophysiology associated with this type of tumor to answer correctly.

*Level of Cognitive Ability:* Analyzing

*Client Needs:* Physiological Integrity

*Integrated Process:* Nursing Process—Assessment

*Content Area:* Adult Health: Oncology

*Health Problem:* Adult Health: Cancer: Esophageal/Gastric/Intestinal

*Priority Concepts:* Cellular Regulation; Clinical Judgment

468. **Answer:** 2
Rationale: Following mastectomy, the arm should be elevated above the level of the heart. Simple arm exercises should be encouraged. No blood pressure readings, injections, intravenous lines, or blood draws should be performed on the affected arm. Cool compresses are not a suggested measure to prevent lymphedema from occurring.

Test-Taking Strategy: Focus on the subject, preventing lymphedema. Note the relationship between the words lymphedema in the question and elevating in the correct option. Also, using general principles related to gravity will direct you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Adult Health: Oncology
Health Problem: Adult Health: Cancer: Breast
Priority Concepts: Clinical Judgment; Tissue Integrity

469. Answer: 1, 3, 5

Rationale: Chronic gastritis causes deterioration and atrophy of the lining of the stomach, leading to the loss of function of the parietal cells. The source of intrinsic factor is lost, which results in an inability to absorb vitamin B_{12}, leading to development of pernicious anemia. Clients must increase their intake of vitamin B_{12} by increasing consumption of foods rich in this vitamin, such as nuts, organ meats, dried beans, citrus fruits, green leafy vegetables, and yeast.

Test-Taking Strategy: Focus on the subject, foods rich in vitamin B_{12}. Note that apples and bananas are comparable or alike in that they are not citrus fruits. This will help you eliminate these options first. Option 2 can also be eliminated because it is not a green leafy vegetable. The remaining options are the correct options.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Adult Health: Hematological
Health Problem: Adult Health: Hematological: Anemias

470. Answer: 2

Rationale: In iron deficiency anemia, iron stores are depleted, resulting in a decreased supply of iron for the manufacture of hemoglobin in red blood cells. An oral iron supplement should be administered through a straw or medicine dropper placed at the back of the mouth, because the iron stains the teeth. The client should be instructed to brush or wipe their teeth after administration. Iron is administered between meals, because absorption is decreased if there is food in the stomach. Iron requires an acid environment to facilitate its absorption in the duodenum. Iron is not mixed with cereal or other food items.

Test-Taking Strategy: Eliminate options 3 and 4 first because they are comparable
or alike and because medication should not be added to formula and food. Next, note the word liquid in the question. This should assist you in recalling that iron in liquid form stains teeth.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Hematological  
**Health Problem:** Adult Health: Hematological: Anemias  
**Priority Concepts:** Client Education; Health Promotion  

471. **Answer:** 4

**Rationale:** In iron deficiency anemia, iron stores are depleted, resulting in a decreased supply of iron for the manufacture of hemoglobin in red blood cells. The results of a complete blood cell count in clients with iron deficiency anemia show decreased hemoglobin levels and microcytic and hypochromic red blood cells. The red blood cell count is decreased. The reticulocyte count is usually normal or slightly elevated.

**Test-Taking Strategy:** Focus on the subject, laboratory findings. Eliminate options 1 and 3 first, knowing that the hemoglobin and red blood cell counts would be decreased. From the remaining options, select the correct option over option 2 because of the relationship between anemia and red blood cells.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Hematological  
**Health Problem:** Adult Health: Hematological: Anemias  
**Priority Concepts:** Cellular Regulation; Gas Exchange  
CHAPTER 45

Oncological and Hematological Medications

Priority Concepts

Cellular Regulation; Safety

Note: Oncological medications are prescribed to treat cancer. Hematological medications are prescribed to treat conditions and diseases related to the blood and blood-forming organs. Blood components are affected when the client receives oncological medications. Hematological medications specific to treating the effects of oncological medications on the body are included in this chapter.

I. Antineoplastic Medications
   A. Description
      1. Antineoplastic medications kill or inhibit the reproduction of neoplastic cells.
      2. Antineoplastic medications are used to cure, increase survival time, and decrease life-threatening complications.
      3. The effect of antineoplastic medications may not be limited to neoplastic cells; normal cells also are affected by the medication.
      4. Cell cycle phase–specific medications affect cells only during a certain phase of the reproductive cycle (Fig. 45-1).
      5. Cell cycle phase–nonspecific medications affect cells in any phase of the reproductive cycle (Fig. 45-1).
      6. Usually, several medications are used in combination to increase the therapeutic response.
      7. Antineoplastic medications may be combined with other treatments, such as surgery and radiation.
      8. Although the intravenous (IV) route is most common for administration, antineoplastic medication may be given by the oral, intra-arterial, isolated limb perfusion, or intracavitary route; dosing is usually based on the client’s body surface area (BSA) and type of cancer.
      9. Chemotherapy dosing is usually based on total BSA, which requires a current, accurate height and weight for BSA calculation (before each medication
administration) to ensure that the client receives optimal doses of chemotherapy medications.

**Side and adverse effects from chemotherapy result from the effects of the antineoplastic medication on normal cells.**

B. Side and adverse effects

1. Mucositis
2. Alopecia
3. Anorexia, nausea, and vomiting
4. Diarrhea
5. Anemia
6. Low white blood cell count (neutropenia)
7. Thrombocytopenia
8. Infertility, sexual alterations
9. Neuropathy

C. General interventions

1. Physiological integrity
   a. Monitor complete blood cell count, white blood cell count, platelet count, uric acid level, and electrolytes.
   b. Initiate bleeding precautions if thrombocytopenia occurs.
   c. When the platelet count is less than 50,000 mm$^3$ (50 × 10$^9$/L), minor trauma can lead to episodes of prolonged bleeding; when less than 20,000 mm$^3$ (20 × 10$^9$/L), spontaneous and uncontrollable bleeding can occur; withhold the medication if the platelet count drops (according to agency policy) and notify the primary health care provider (PHCP). Bleeding precautions are initiated.
   d. Monitor for petechiae, ecchymoses, bleeding of the gums, and nosebleeds, because the decreased platelet count can precipitate bleeding tendencies.
   e. Avoid intramuscular injections and venipunctures as much as possible to prevent bleeding.
   f. Withhold the medication and initiate neutropenic precautions if the segmented neutrophil count decreases
below 18% conventional units (0.18 SI units); notify the PHCP.
g. Monitor for fever, sore throat, unusual bleeding, and signs and symptoms of infection.
h. Inform the client that loss of appetite also may be the result of taste changes or a bitter taste in the mouth from the medications.
i. Monitor for nausea and vomiting and provide a high-calorie diet with protein supplements.
j. Administer antiemetics several hours before chemotherapy and for 12 to 48 hours after as prescribed, because antineoplastic medications stimulate the vomiting center in the brain.
k. Encourage hydration; IV fluids are administered before and during therapy.
l. Promote a fluid intake of at least 2000 mL/day to maintain adequate renal function.

Antineoplastic medication causes the rapid destruction of cells, resulting in the release of uric acid. Allopurinol may be prescribed to lower the serum uric acid level.

2. Safe and effective care environment
   a. Prepare IV chemotherapy in an air-vented space (biological safety cabinet).
   b. Wear appropriate personal protective equipment (PPE), including gloves, gown, eye protectors, and mask as indicated, to reduce exposure whenever there is a risk of hazardous medications being released into the environment.
   c. Nurses who are pregnant should avoid chemotherapy preparation or the administration of chemotherapy.
   d. Discard IV equipment in designated (biohazard) containers.
   e. Administer antineoplastic medication precisely as prescribed to maximize antineoplastic effects while allowing
normal cells to recover.
f. Monitor for phlebitis with IV administration, because these medications may irritate the veins.
g. Vesicants should be administered through a central line when possible; if a peripheral line is used, blood return should be checked prior to administration.
h. As prescribed, reduce IV site pain by altering IV rates or warming the injection site to distend the vein and increase blood flow.
i. Monitor for extravasation (leakage of medication into surrounding skin and subcutaneous tissue, which causes tissue necrosis) and notify the PHCP if this occurs; heat or ice is applied depending on the medication, and an antidote may be injected into the site.

3. Psychosocial integrity
   a. Instruct the client about the possibility of hair loss and that varying degrees of hair loss may occur after the first or second treatment.
   b. Discuss the purchase of a wig before treatment starts and consider cutting hair short.
   c. Inform the client that new hair growth will occur several months after the final treatment.
   d. Instruct the client about the need for contraception, because these medications have teratogenic effects.
   e. Discuss the potential effect of infertility, which may be irreversible.
   f. Encourage pretreatment counseling and encourage sperm banking or preservation of eggs if the client is still of childbearing age.

4. Health promotion and maintenance
   a. Instruct the client, if diarrhea is a problem, to avoid spicy foods, high-fiber foods, and foods that are hot in temperature, which increase peristalsis.
   b. Instruct the client to inspect the oral mucosa frequently for erythema and
ulcers, rinse the mouth after meals, and carry out good oral hygiene.
c. Instruct the client to use mouth rinses as prescribed for mouth sores if necessary.
d. Instruct the client in the use of antifungal agents for mouth sores, if prescribed, for the development of a fungal infection.
e. Instruct the client to avoid crowds and persons with infections and to report signs of infection such as a low-grade fever, chills, or sore throat.
f. Instruct individuals with colds or infections to wear a mask when visiting or to avoid visiting the client.
g. Instruct the client to use a soft toothbrush and electric razor to minimize the risk of bleeding.
h. Instruct the client to avoid aspirin-containing products to minimize the risk of bleeding.
i. Instruct the client to consult the PHCP before receiving vaccinations (live vaccines should not be administered).

D. Anaphylactic reactions
1. Precautions
   a. Obtain an allergy history.
   b. Administer a test dose when prescribed by the PHCP.
      c. Stay with the client during the administration of medication.
   d. Monitor vital signs.
   e. Have emergency equipment and medications readily available.
      f. Initiate IV access for the administration of emergency medications if needed.

2. Signs of an anaphylactic reaction
   a. Dyspnea
   b. Chest tightness or pain
   c. Pruritus or urticaria
   d. Tachycardia
   e. Dizziness
f. Anxiety or agitation
g. Flushed appearance
h. Hypotension
i. Decreased sensorium
j. Cyanosis

3. Interventions for an anaphylactic reaction (see Priority Nursing Actions)

Priority Nursing Actions

Anaphylactic Reaction Occurring from Medication
1. Assess respiratory status.
2. Stop the medication.
3. Contact the primary health care provider (PHCP) and the Rapid Response Team if necessary.
4. Administer oxygen.
5. Maintain the intravenous (IV) access with normal saline.
6. Raise the client’s feet and legs, if not contraindicated.
7. Administer prescribed emergency medications, such as epinephrine.
8. Monitor vital signs.

Reference

II. Alkylating Medications (Box 45-1)
A. Description
1. Break the DNA helix, thereby interfering with DNA replication
2. Cell cycle phase–nonspecific medications
B. Side and adverse effects
1. Anorexia, nausea, and vomiting may occur.
2. Stomatitis may occur.
3. Rash may occur.
4. Client may feel IV site pain during IV administration.
5. Busulfan may cause hyperuricemia.
6. Chlorambucil and mechlorethamine may cause gonadal suppression and hyperuricemia.
7. Cisplatin, a platinum compound, may cause ototoxicity, tinnitus, hypokalemia, hypocalcemia, hypomagnesemia, and nephrotoxicity.
C. Interventions: Refer to Section I, C (Antineoplastic Medications—General Interventions).
1. Cyclophosphamide may cause alopecia, gonadal suppression, hemorrhagic cystitis, and hematuria.
2. Ifosfamide may cause hemorrhagic cystitis, and neurotoxicity.
3. Assess results of pulmonary function tests.
4. Assess results of chest radiography and renal and liver...
When administering cisplatin, assess the client for dizziness, tinnitus, hearing loss, incoordination, and numbness or tingling of extremities.

6. Mesna may be administered with ifosfamide to reduce the potential for ifosfamide-induced cystitis.

7. Instruct the client that cyclophosphamide, when prescribed orally, is administered without food.

8. Instruct the client to follow a diet low in purines to alkalinize the urine and lower uric acid blood levels.

9. Instruct the client about how to avoid infection.

10. Instruct the client to report signs of infection or bleeding.

11. Instruct the client about good oral hygiene and the use of a soft toothbrush.

III. Antitumor Antibiotic Medications (Box 45-2)

A. Description

1. Interfere with DNA and RNA synthesis

2. Cell cycle phase–nonspecific medications

B. Side and adverse effects

1. Nausea and vomiting

2. Fever

3. Bone marrow depression

4. Rash

5. Alopecia

6. Stomatitis

7. Gonadal suppression

8. Hyperuricemia

9. Vesication (blistering of tissue at IV site)

10. Daunorubicin may cause heart failure and dysrhythmias.

11. Doxorubicin and idarubicin may cause cardiotoxicity, cardiomyopathy, and electrocardiographic changes (dexrazoxane, which is a cardioprotective agent, may be administered with doxorubicin to reduce cardiomyopathy).

12. Pulmonary toxicity can occur with bleomycin.
C. Interventions: Refer to Section I, C (Antineoplastic Medications—General Interventions).

1. Assess results of pulmonary function tests.
2. Monitor for electrocardiographic changes.
3. Assess lung sounds for crackles.
4. Assess for signs of heart failure, including dyspnea, crackles, peripheral edema, and weight gain.
5. Assess results of chest radiography and renal and liver function studies.
6. Assess for myocardial toxicity, dyspnea, dysrhythmias, hypotension, and weight gain when administering doxorubicin or idarubicin.
7. Monitor pulmonary status when administering bleomycin.

IV. Antimetabolite Medications (Box 45-3)

A. Description

1. Antimetabolite medications halt the synthesis of cell protein; their presence impairs cell division.
2. Antimetabolite medications are cell cycle phase-specific and affect the S phase.

B. Side and adverse effects

1. Anorexia, nausea, and vomiting
2. Diarrhea
3. Alopecia
4. Stomatitis
5. Depression of bone marrow
6. Cytarabine may cause alopecia, stomatitis, hyperuricemia, and hepatotoxicity.

7. Fluorouracil may cause alopecia, stomatitis, diarrhea, phototoxicity reactions, and cerebellar dysfunction.
8. Mercaptopurine may cause hyperuricemia and hepatotoxicity.
9. Methotrexate may cause alopecia; stomatitis; hyperuricemia; photosensitivity; hepatotoxicity; and hematological, gastrointestinal, and skin toxicity.

C. Interventions: Refer to Section I, C (Antineoplastic Medications—General Interventions).

1. Monitor renal function studies.
2. Monitor for cerebellar dysfunction.
3. Assess for photosensitivity.
4. When administering fluorouracil, assess for signs of
cerebellar dysfunction, such as dizziness, weakness,
and ataxia, and assess for stomatitis and diarrhea,
which may necessitate medication discontinuation.
5. When administering fluorouracil or methotrexate,
instruct the client to use sunscreen and wear
protective clothing to prevent photosensitivity
reactions.

When administering methotrexate in large doses, prepare to
administer leucovorin as prescribed to prevent toxicity. This is known as
leucovorin rescue.

V. Mitotic Inhibitor Medications (*Vinca* Alkaloids) (Box 45-4)
A. Description
1. Mitotic inhibitors prevent mitosis, causing cell death.
2. Mitotic inhibitors are cell cycle phase–specific and act
on the M phase.

B. Side and adverse effects
1. Leukopenia
2. Neurotoxicity with vincristine, manifested as
   numbing and tingling in the fingers and toes;
   constipation, and paralytic ileus can also occur.
3. Ptosis
4. Hoarseness
5. Motor instability
6. Anorexia, nausea, and vomiting
7. Peripheral neuropathy
8. Alopecia
9. Stomatitis
10. Hyperuricemia
11. Phlebitis at IV site

C. Interventions: Refer to Section I, C (Antineoplastic
Medications—General Interventions).
1. Monitor for hoarseness.
2. Assess eyes for ptosis.
3. Assess motor stability and initiate safety precautions
   as necessary.
4. Monitor for neurotoxicity with vincristine, manifested
   as numbness and tingling in the fingers and toes.
5. Monitor for constipation and paralytic ileus.

VI. Topoisomerase Inhibitors (Box 45-5)
A. Description
1. Block an enzyme needed for DNA synthesis and cell
division
2. Cell cycle phase-specific; act on the G₂ and S phases

B. Side and adverse effects
1. Leukopenia, thrombocytopenia, and anemia
2. Anorexia, nausea, and vomiting
3. Diarrhea
4. Alopecia
5. Orthostatic hypotension
6. Hypersensitivity reaction

C. Interventions: Refer to Section I, C (Antineoplastic Medications—General Interventions).

VII. Hormonal Medications and Enzymes (Box 45-6)

A. Description
1. Suppress the immune system and block normal hormones in hormone-sensitive tumors
2. Change the hormonal balance and slow the growth rates of certain tumors

B. Side and adverse effects
1. Anorexia, nausea, and vomiting
2. Leukopenia
3. Impaired pancreatic function with asparaginase
4. Sex characteristic alterations
   a. Masculinizing effect in women: Chest and facial hair, menses stops
   b. Feminine manifestations in men: Gynecomastia
5. Breast swelling
6. Hot flashes
7. Weight gain
8. Hemorrhagic cystitis, hypouricemia, and hypercholesterolemia, with mitotane
9. Hypertension
10. Thromboembolic disorders
11. Edema
12. Electrolyte imbalances
13. Tamoxifen citrate may cause edema, hypercalcemia, and elevated cholesterol and triglyceride levels.
14. Tamoxifen citrate decreases the effects of estrogen.

C. Interventions: Refer to Section I, C (Antineoplastic Medications—General Interventions).
1. Assess medications that the client is taking currently.
2. Monitor serum calcium levels with androgens.
3. Monitor for signs of alterations in sexual characteristics.
4. Monitor pancreatic function with asparaginase.
5. Monitor uric acid and cholesterol levels.
6. Monitor for signs of hemorrhagic cystitis.

VIII. Immunomodulator (Immunotherapy) Agents: Biological Response Modifiers (Box 45-7)
   A. Description
      1. Immunomodulators stimulate the immune system to recognize cancer cells and take action to eliminate or destroy them.
      2. Interleukins help various immune system cells to recognize and destroy abnormal body cells.
      3. Interferons slow tumor cell division, stimulate proliferation, and cause cancer cells to differentiate into nonproliferative forms.
   B. Colony-stimulating factors induce more rapid bone marrow recovery after suppression by chemotherapy (Box 45-8).

IX. Targeted Therapy
   A. Description: (see Box 45-7)
      1. Medications used as targeted therapies are monoclonal antibodies and small molecule inhibitors that target a cellular element of the cancer cell or antisense medications that work at the gene level.
      2. Examples of monoclonal antibodies are rituximab, trastuzumab, alemtuzumab, bevacizumab, and cetuximab.
   B. Adverse effects: Allergic reactions (monoclonal antibodies)

X. Other Antineoplastic Medications
   A. Altretamine: Cytotoxic agent used to treat ovarian cancer
   B. Denileukin diftitox: Recombinant DNA-derived medication used to treat cutaneous T-cell lymphoma
   C. Pegaspargase: Used in combination chemotherapies for acute lymphoblastic leukemia in clients unable to take asparaginase
   D. Bexarotene: Used to treat advanced-stage cutaneous T-cell lymphoma

XI. Medications to Treat Anemia (see Chapter 44 for more information)
   A. Iron-deficiency anemia: Iron, oral or intravenous
   B. Vitamin B₁₂-deficiency anemia: Vitamin B₁₂, oral or intramuscular
   C. Folate-deficiency anemia: Folate, oral
   D. Acute blood loss anemia: Blood transfusion, packed red blood cells, platelets, or fresh frozen plasma depending on cause
   E. Anemia of chronic disease: Iron, oral or intravenous, erythropoietic growth factors, leukopoietic growth factors, and thrombopoietic growth factors (see Chapter 55 for more information).
FIG. 45-1 The cell cycle. G1, the cell is preparing for division; S (synthesis phase/DNA replication), the cell doubles its DNA content through DNA synthesis; G2, the cell produces proteins to be used in cell division and in normal physiological function after cell division is complete; M (mitotic phase), the single cell splits apart into 2 cells.

Box 45-1
Alkylation Medications

Nitrogen Mustards
- Bendamustine
- Chlorambucil
- Cyclophosphamide
- Ifosfamide
- Estramustine
- Mechlorethamine
- Melphalan

Nitrosoureas
- Carmustine
- Lomustine
- Streptozocin

Alkylation-Like Medications
- Altretamine
- Busulfan
- Carboplatin
- Cisplatin
- Dacarbazine
- Oxaliplatin
- Temozolomide
- Thiotepa
**Box 45-2**

**Antitumor Antibiotic Medications**

- Bleomycin sulfate
- Dactinomycin
- Daunorubicin
- Doxorubicin
- Epirubicin
- Idarubicin
- Mitomycin
- Mitoxantrone
- Valrubicin

**Box 45-3**

**Antimetabolite Medications**

- Azacitidine
- Capecitabine
- Cladribine
- Clofarabine
- Cytarabine
- Decitabine
- Floxuridine
- Fludarabine
- Fluorouracil
- Gemcitabine
- Hydroxyurea
- Mercaptopurine
- Methotrexate
- Nelarabine
- Pemetrexed
- Pentostatin
- Pralatrexate
- Thioguanine
- Uracil

**Box 45-4**

1357
Mitotic Inhibitors

**Vinca Alkaloids**

- Vinblastine sulfate
- Vincristine sulfate
- Vinorelbine

**Taxanes**

- Docetaxel
- Paclitaxel

**Box 45-5**

**Topoisomerase Inhibitors**

- Etoposide
- Irinotecan
- Teniposide
- Topotecan

**Box 45-6**

**Hormonal Medications and Enzymes**

**Estrogens**

- Estramustine
- Ethinyl estradiol

**Antiestrogens**

- Anastrozole
- Exemestane
- Fulvestrant
- Letrozole
- Raloxifene
- Tamoxifen citrate
- Toremifene
Antiandrogens

- Bicalutamide
- Enzalutamide
- Flutamide
- Goserelin acetate
- Histrelin
- Nilutamide
- Triptorelin

Progestins

- Medroxyprogesterone
- Megestrol acetate

Other Hormonal Antagonists and Enzymes

- Asparaginase
- Leuprolide acetate
- Mitotane

Box 45-7

Immunomodulators and Targeted Therapies

Interleukins and Interferons

- Aldesleukin
- Interferon α-2a
- Interferon α-2b
- Interferon α-n3
- Recombinant interferon α-2a
- Recombinant interferon α-2b

Common Monoclonal Antibodies

- Bevacizumab
- Cetuximab
- Ibritumomab
- Infliximab
- Panitumumab
- Pembrolizumab
• Rituximab
• Trastuzumab

Small Molecule Inhibitors

• Bortezomib
• Dasatinib
• Erlotinib
• Gefitinib
• Imatinib
• Lapatinib
• Nilotinib
• Sorafenib
• Sunitinib
• Temsirolimus

Box 45-8

**Colony-Stimulating Factors**

Granulocyte Macrophage Colony–Stimulating Factor

• Sargramostim

Granulocyte Colony–Stimulating Factor

• Filgrastim
• Pegfilgrastim

Erythropoietin

• Epoetin α
• Darbepoetin α

Thrombopoietic Growth Factor

• Oprelvekin

Practice Questions

472. Chemotherapy dosage is frequently based on total body surface area (BSA), so it is important for the nurse to perform which assessment before
administering chemotherapy?
1. Measure the client’s abdominal girth.
2. Calculate the client’s body mass index.
3. Measure the client’s current weight and height.
4. Ask the client about his or her weight and height.

473. A client with squamous cell carcinoma of the larynx is receiving bleomycin intravenously. The nurse caring for the client anticipates that which diagnostic study will be prescribed?
1. Echocardiography
2. Electrocardiography
3. Cervical radiography
4. Pulmonary function studies

474. A client with acute myelocytic leukemia is being treated with busulfan. Which laboratory value would the nurse specifically monitor during treatment with this medication?
1. Clotting time
2. Uric acid level
3. Potassium level
4. Blood glucose level

475. A client with small cell lung cancer is being treated with etoposide. The nurse monitors the client during administration, knowing that which adverse effect is specifically associated with this medication?
1. Alopecia
2. Chest pain
3. Pulmonary fibrosis
4. Orthostatic hypotension

476. A clinic nurse prepares a teaching plan for a client receiving an antineoplastic medication. When implementing the plan, the nurse should make which statement to the client?
1. “You can take aspirin as needed for headache.”
2. “You can drink beverages containing alcohol in moderate amounts each evening.”
3. “You need to consult with the primary health care provider (PHCP) before receiving immunizations.”
4. “It is fine to receive a flu vaccine at the local health fair without PHCP approval because the flu is so contagious.”

477. A client with ovarian cancer is being treated with vincristine. The nurse monitors the client, knowing that which manifestation indicates an adverse effect specific to this medication?
1. Diarrhea
2. Hair loss
3. Chest pain
4. Peripheral neuropathy

478. The nurse is reviewing the history and physical examination of a client who will be receiving asparaginase, an antineoplastic agent. The nurse contacts the primary health care provider before administering the medication if which disorder is documented in the client’s history?
1. Pancreatitis
2. Diabetes mellitus
3. Myocardial infarction
4. Chronic obstructive pulmonary disease

479. Tamoxifen citrate is prescribed for a client with metastatic breast carcinoma. The client asks the nurse if her family member with bladder cancer can also take this medication. The nurse most appropriately responds by making which statement?
1. “This medication can be used only to treat breast cancer.”
2. “Yes, your family member can take this medication for bladder cancer as well.”
3. “This medication can be taken to prevent and treat clients with breast cancer.”
4. “This medication can be taken by anyone with cancer as long as their health care provider approves it.”

480. A client with metastatic breast cancer is receiving tamoxifen. The nurse specifically monitors which laboratory value while the client is taking this medication?
1. Glucose level
2. Calcium level
3. Potassium level
4. Prothrombin time

481. Megestrol acetate, an antineoplastic medication, is prescribed for a client with metastatic endometrial carcinoma. The nurse reviews the client’s history and should contact the primary health care provider if which diagnosis is documented in the client’s history?
1. Gout
2. Asthma
3. Myocardial infarction
4. Venous thromboembolism

482. The nurse is monitoring the intravenous (IV) infusion of an antineoplastic medication. During the infusion, the client complains of pain at the insertion site. On inspection of the site, the nurse notes redness and swelling and that the infusion of the medication has slowed in rate. The nurse suspects extravasation and should take which actions? Select all that apply.
1. Stop the infusion.
2. Prepare to apply ice or heat to the site.
3. Restart the IV at a distal part of the same vein.
4. Notify the primary health care provider (PHCP).
5. Prepare to administer a prescribed antidote into the site.
6. Increase the flow rate of the solution to flush the skin and subcutaneous tissue.

483. The nurse is analyzing the laboratory results of a client with leukemia who has received a regimen of chemotherapy. Which laboratory value would the nurse specifically note as a result of the massive cell destruction that occurred from the chemotherapy?
1. Anemia
2. Decreased platelets
3. Increased uric acid level
4. Decreased leukocyte count

484. The nurse is providing medication instructions to a client with breast cancer who is receiving cyclophosphamide. The nurse should tell the client to take which action?

1. Take the medication with food.
2. Increase fluid intake to 2000 to 3000 mL daily.
3. Decrease sodium intake while taking the medication.
4. Increase potassium intake while taking the medication.

485. A client with non-Hodgkin’s lymphoma is receiving daunorubicin. Which finding would indicate to the nurse that the client is experiencing an adverse effect related to the medication?

1. Fever
2. Sores in the mouth and throat
3. Complaints of nausea and vomiting
4. Crackles on auscultation of the lungs

486. The nurse is monitoring the laboratory results of a client receiving an antineoplastic medication by the intravenous route. The nurse plans to initiate bleeding precautions if which laboratory result is noted?

1. A clotting time of 10 minutes
2. An ammonia level of 10 mcg/dL (6 mcmol/L).
3. A platelet count of 50,000 mm$^3$ (50 × 10$^9$/L)
4. A white blood cell count of 5000 mm$^3$ (5.0 × 10$^9$/L)

Answers

472. Answer: 3

Rationale: To ensure that the client receives optimal doses of chemotherapy, dosing is usually based on the total BSA, which requires a current accurate height and weight for BSA calculation (before each medication administration). Asking the client about his or her height and weight may lead to inaccuracies in determining a true BSA and dosage. Calculating body mass index and measuring abdominal girth will not provide the data needed.

Test-Taking Strategy: Recall the basis for dosing chemotherapy. Recalling that a current accurate height and weight need to be obtained for BSA calculation and chemotherapy dosing will direct you to the correct option. Eliminate option 4 because it is an unreliable way of obtaining the information. Next, eliminate options 1 and 2 because they are comparable or alike and do not relate to chemotherapy dosing.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment

Health Problem: N/A
Priority Concepts: Cellular Regulation; Clinical Judgment
473. Answer: 4

**Rationale:** Bleomycin is an antineoplastic medication that can cause interstitial pneumonitis, which can progress to pulmonary fibrosis. Pulmonary function studies along with hematological, hepatic, and renal function tests need to be monitored. The nurse needs to monitor lung sounds for dyspnea and crackles, which indicate pulmonary toxicity. The medication needs to be discontinued immediately if pulmonary toxicity occurs. Options 1, 2, and 3 are unrelated to the specific use of this medication.

**Test-Taking Strategy:** Eliminate options 1 and 2 first because they are cardiac related and are therefore comparable or alike. From the remaining options, use the ABCs—airway, breathing, and circulation—to direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Analysis

**Content Area:** Pharmacology: Oncology Medications: Antitumor Antibiotics

**Health Problem:** Adult Health: Cancer: Laryngeal and Lung

**Priority Concepts:** Cellular Regulation; Clinical Judgment

474. Answer: 2

**Rationale:** Busulfan can cause an increase in the uric acid level. Hyperuricemia can produce uric acid nephropathy, renal stones, and acute kidney injury. Options 1, 3, and 4 are not specifically related to this medication.

**Test-Taking Strategy:** Focus on the subject, a specific laboratory value. It is necessary to know the adverse effects associated with this medication. Recalling that busulfan increases the uric acid level will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Pharmacology: Oncology Medications: Alkylating

**Health Problem:** Adult Health: Cancer: Leukemia

**Priority Concepts:** Cellular Regulation; Clinical Judgment

475. Answer: 4

**Rationale:** An adverse effect specific to etoposide is orthostatic hypotension. Etoposide should be administered slowly over 30 to 60 minutes to avoid hypotension. The client’s blood pressure is monitored during the infusion. Hair loss occurs with nearly all antineoplastic medications. Chest pain and pulmonary fibrosis are unrelated to this medication.

**Test-Taking Strategy:** Eliminate option 1 first, because this adverse effect is associated with many of the antineoplastic agents. Eliminate options 2 and 3 next because they are comparable or alike and are unrelated to etoposide. Note that the question asks for the adverse effect specific to this medication. Correlate hypotension
with etoposide.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Oncology Medications: Topoisomerase Inhibitors  
**Health Problem:** Adult Health: Cancer: Laryngeal and Lung  
**Priority Concepts:** Cellular Regulation; Clinical Judgment  

476. **Answer:** 3

**Rationale:** Because antineoplastic medications lower the resistance of the body, clients must be informed not to receive immunizations without the PHCP’s approval. Clients also need to avoid contact with individuals who have recently received a live virus vaccine. Clients need to avoid aspirin and aspirin-containing products to minimize the risk of bleeding, and they need to avoid alcohol to minimize the risk of toxicity and side/adverse effects.

**Test-Taking Strategy:** Focus on the subject, client teaching about an antineoplastic medication, and think about the side/adverse effects of antineoplastic medications. Recalling that antineoplastic medications lower the resistance of the body will direct you to the correct option.

**Level of Cognitive Ability:** Applying

[www.hrsa.gov/vaccinecompensation/index.html](http://www.hrsa.gov/vaccinecompensation/index.html)

477. **Answer:** 4

**Rationale:** An adverse effect specific to vincristine is peripheral neuropathy, which occurs in almost every client. Peripheral neuropathy can be manifested as numbness and tingling in the fingers and toes. Depression of the Achilles tendon reflex may be the first clinical sign indicating peripheral neuropathy. Constipation rather than diarrhea is most likely to occur with this medication, although diarrhea may occur occasionally. Hair loss occurs with nearly all antineoplastic medications. Chest pain is unrelated to this medication.

**Test-Taking Strategy:** Eliminate options 1 and 2 first because they are comparable or alike and are side/adverse effects associated with many of the antineoplastic agents. Note that the question asks for the adverse effect specific to this medication. Correlate peripheral neuropathy with vincristine.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment

Health Problem: Adult Health: Cancer: Cervical/Uterine/Ovarian
Priority Concepts: Cellular Regulation; Clinical Judgment

478. Answer: 1

Rationale: Asparaginase is contraindicated if hypersensitivity exists, in pancreatitis, or if the client has a history of pancreatitis. The medication impairs pancreatic function, and pancreatic function tests should be performed before therapy begins and when a week or more has elapsed between dose administrations. The client needs to be monitored for signs of pancreatitis, which include nausea, vomiting, and abdominal pain. The conditions noted in options 2, 3, and 4 are not contraindicated with this medication.

Test-Taking Strategy: Focus on the subject, a contraindication of asparaginase. It is necessary to know the contraindications associated with this medication. Recalling that this medication affects pancreatic function will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Pharmacology: Oncology Medications: Hormonal and Enzymes
Health Problem: N/A
Priority Concepts: Cellular Regulation; Clinical Judgment

479. Answer: 3

Rationale: Tamoxifen is an antineoplastic medication that competes with estradiol for binding to estrogen in tissues containing high concentrations of receptors. Tamoxifen is used to treat metastatic breast carcinoma in women and men. Tamoxifen is also effective in delaying the recurrence of cancer following mastectomy and for preventing breast cancer in those that are at high risk.

Test-Taking Strategy: Note the strategic words, most appropriately. Recalling that this medication is used for breast cancer will assist you in eliminating options 2 and 4. Note the closed-ended word “only” in option 1 to assist you in eliminating this option. Also, recall that this medication is used for both prevention and treatment of breast cancer.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Pharmacology: Oncology Medications: Selective Estrogen Receptor Modulators
Health Problem: Adult Health: Cancer: Breast
Priority Concepts: Cellular Regulation; Clinical Judgment
Reference: Lewis et al. (2017), 1217.

480. Answer: 2
**Rationale:** Tamoxifen may increase calcium, cholesterol, and triglyceride levels. Before the initiation of therapy, a complete blood count, platelet count, and serum calcium level should be assessed. These blood levels, along with cholesterol and triglyceride levels, should be monitored periodically during therapy. The nurse should assess for hypercalcemia while the client is taking this medication. Signs of hypercalcemia include increased urine volume, excessive thirst, nausea, vomiting, constipation, hypotonicity of muscles, and deep bone and flank pain.

**Test-Taking Strategy:** Focus on the subject, the laboratory value to monitor for tamoxifen. Think about the action of this medication. Recalling that this medication causes hypercalcemia will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Pharmacology: Oncology Medications: Selective Estrogen Receptor Modulators

**Health Problem:** Adult Health: Cancer: Breast

**Priority Concepts:** Cellular Regulation; Fluids and Electrolytes

481. **Answer:** 4

**Rationale:** Megestrol acetate suppresses the release of luteinizing hormone from the anterior pituitary by inhibiting pituitary function and regressing tumor size. Megestrol is used with caution if the client has a history of venous thromboembolism. Options 1, 2, and 3 are not contraindications for this medication.

**Test-Taking Strategy:** Focus on the subject, a contraindication to megestrol acetate. It is necessary to know the adverse effects associated with this medication. Recalling that megestrol acetate is a hormonal antagonist enzyme and that an adverse effect is thrombotic disorders will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Pharmacology: Oncology Medications: Hormonal and Enzymes

**Health Problem:** Adult Health: Cancer: Cervical/Uterine/Ovarian

**Priority Concepts:** Clinical Judgment; Safety

482. **Answer:** 1, 2, 4, 5

**Rationale:** Redness and swelling and a slowed infusion indicate signs of extravasation. If the nurse suspects extravasation during the IV administration of an antineoplastic medication, the infusion is stopped and the PHCP is notified. Ice or heat may be prescribed for application to the site, and an antidote may be prescribed to be administered into the site. Increasing the flow rate can increase damage to the tissues. Restarting an IV in the same vein can increase damage to the site and vein.

**Test-Taking Strategy:** Focus on the assessment signs in the question and the words suspects extravasation. Visualize the situation to identify the nursing actions.
Think about the actions that will cause further damage. Note that options 3 and 6 are comparable or alike and can cause further damage.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Complex Care: Emergency Situations/Management  
**Health Problem:** Adult Health: Integumentary: Inflammations/Infections  
**Priority Concepts:** Clinical Judgment; Tissue Integrity  

483. **Answer:** 3

**Rationale:** Hyperuricemia is especially common following treatment for leukemias and lymphomas, because chemotherapy results in massive cell kill. Although options 1, 2, and 4 also may be noted, an increased uric acid level is related specifically to cell destruction.

**Test-Taking Strategy:** Focus on the **subject**, the laboratory value that reflects massive cell destruction. Remember that uric acid is released when cells are destroyed. This will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Oncology  
**Health Problem:** Adult Health: Cancer: Leukemia  
**Priority Concepts:** Cellular Regulation; Clinical Judgment  
**Reference:** Lewis et al. (2017), p. 252.

484. **Answer:** 2

**Rationale:** Hemorrhagic cystitis is an adverse effect that can occur with the use of cyclophosphamide. The client needs to be instructed to drink copious amounts of fluid during the administration of this medication. Clients also should monitor urine output for hematuria. The medication should be taken on an empty stomach, unless gastrointestinal upset occurs. Hyperkalemia can result from the use of the medication; therefore, the client would not be told to increase potassium intake. The client would not be instructed to alter sodium intake.

**Test-Taking Strategy:** Focus on the **subject**, client teaching about cyclophosphamide. Recalling that cyclophosphamide can cause hemorrhagic cystitis will direct you to the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Pharmacology: Oncology Medications: Alkylating  
**Health Problem:** Adult Health: Cancer: Breast  
**Priority Concepts:** Cellular Regulation; Client Education  
**Reference:** Lewis et al. (2017), p. 1522.
**Rationale:** Cardiotoxicity noted by abnormal electrocardiographic findings or cardiomyopathy manifested as heart failure (lung crackles) is an adverse effect of daunorubicin. Bone marrow depression is also an adverse effect. Fever is a frequent side effect, and sores in the mouth and throat can occur occasionally. Nausea and vomiting is a frequent side effect associated with the medication that begins a few hours after administration and lasts 24 to 48 hours. Options 1, 2, and 3 are not adverse effects.

**Test-Taking Strategy:** Keep in mind that the question is asking about an adverse effect. Use of the ABCs—airway, breathing, and circulation—will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Analysis

**Content Area:** Pharmacology: Oncology Medications: Antitumor Antibiotics

**Health Problem:** Adult Health: Cancer: Lymphoma: Hodgkin’s and non-Hodgkins

**Priority Concepts:** Cellular Regulation; Clinical Judgment

---

**Rationale:** Bleeding precautions need to be initiated when the platelet count decreases. The normal platelet count is 150,000 to 450,000 mm$^3$ (150 to 400 × 10$^9$/L). When the platelet count decreases, the client is at risk for bleeding. The normal white blood cell count is 5000 to 10,000 mm$^3$ (5.0 to 10.0 × 10$^9$/L). When the white blood cell count drops, neutropenic precautions need to be implemented. The normal clotting time is 8 to 15 minutes. The normal ammonia value is 10 to 80 mcg/dL (6 to 47 mcmol/L).

**Test-Taking Strategy:** Use knowledge regarding normal laboratory values. Options 1, 2, and 4 are comparable or alike and identify normal laboratory values. Remember to correlate a low platelet count with the need for bleeding precautions and a low white blood cell count with the need for neutropenic precautions.

**Level of Cognitive Ability:** Synthesizing

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Planning

**Content Area:** Foundations of Care: Safety

**Health Problem:** Adult Health: Hematological: Bleeding/Clotting Disorders

UNIT IX
Endocrine Problems of the Adult Client
Introduction

Pyramid to Success

The endocrine system is made up of organs or glands that secrete hormones and release them directly into the circulation. The endocrine system can be understood easily if you remember that basically 1 of 2 situations can occur—hypersecretion or hyposecretion of hormones from the organ or gland. When an excess of the hormone occurs, treatment is aimed at blocking the hormone release through medication or surgery. When a deficit of the hormone exists, treatment is aimed at replacement therapy. Pyramid Points focus on diabetes mellitus, including its prevention, the prevention and treatment of complications, insulin therapy, hypoglycemic and hyperglycemic reactions, and acute and chronic complications of diabetes; Addison’s disease and addisonian crisis; Cushing’s disease or Cushing’s syndrome; thyroid problems and thyroid storm; and care of the client after thyroidectomy or adrenalectomy.

Client Needs: Learning Objectives

Safe and Effective Care Environment

Acting as a client advocate
Collaborating with the interprofessional team and appropriate care providers regarding treatment
Ensuring that informed consent for treatments and procedures has been obtained
Establishing priorities of care
Handling hazardous and infectious materials
Maintaining confidentiality related to the health problem
Preventing accidents and client injury
Using medical and surgical asepsis to prevent infection

Health Promotion and Maintenance

Discussing expected body image changes
Identifying lifestyle choices related to treatment
Performing physical assessment of the endocrine system
Preventing health problems
Providing health screening
Teaching about self-care measures

**Psychosocial Integrity**

Discussing grief and loss issues related to complications of the health problem
Discussing situational role changes related to the health problem
Discussing unexpected body image changes
Identifying coping mechanisms
Monitoring for sensory and perceptual alterations as a result of the health problem
Using support systems

**Physiological Integrity**

Monitoring for alterations in body systems as a result of the health problem
Monitoring for complications from surgical procedures and health alterations
Monitoring for complications of diagnostic tests, treatments, and procedures
Monitoring for expected outcomes and effects of pharmacological therapy
Monitoring for fluid and electrolyte imbalances that can occur
Monitoring for unexpected response to therapies
Monitoring laboratory values
Preparing the client for diagnostic tests
Providing emergency care to the client
Providing nonpharmacological comfort interventions
Providing nutrition and oral hydration measures

   B. Risk factors for endocrine problems (Box 46-2)
   C. Hypothalamus (Box 46-3)
      1. Portion of the diencephalon of the brain, forming the
         floor and part of the lateral wall of the third ventricle
      2. Activates, controls, and integrates the peripheral
         autonomic nervous system, endocrine processes, and
         many somatic functions, such as body temperature,
         sleep, and appetite
   D. Pituitary gland (Box 46-4; Fig. 46-1)
      1. The master gland; located at the base of the brain
      2. Influenced by the hypothalamus; directly affects the
         function of the other endocrine glands
      3. Promotes growth of body tissue, influences water
         absorption by the kidney, and controls sexual
         development and function
   E. Adrenal gland
      1. One adrenal gland is on top of each kidney.
      2. Regulates sodium and electrolyte balance; affects
         carbohydrate, fat, and protein metabolism; influences
         the development of sexual characteristics; and
         sustains the fight-or-flight response
      3. Adrenal cortex
         a. The cortex is the outer shell of the
            adrenal gland.
         b. The cortex synthesizes glucocorticoids
            and mineralocorticoids and secretes
small amounts of sex hormones (androgens, estrogens; Box 46-5)

4. Adrenal medulla
   a. The medulla is the inner core of the adrenal gland.
   b. The medulla works as part of the sympathetic nervous system and produces epinephrine and norepinephrine.

F. Thyroid gland
   1. Located in the anterior part of the neck
   2. Controls the rate of body metabolism and growth and produces thyroxine ($T_4$), triiodothyronine ($T_3$), and thyrocalcitonin

G. Parathyroid glands
   1. Located on the thyroid gland
   2. Controls calcium and phosphorus metabolism; produces parathyroid hormone

H. Pancreas
   1. Located posteriorly to the stomach
   2. Influences carbohydrate metabolism, indirectly influences fat and protein metabolism, and produces insulin and glucagon

I. Ovaries and testes
   1. The ovaries are located in the pelvic cavity and produce estrogen and progesterone.
   2. The testes are located in the scrotum, control the development of the secondary sex characteristics, and produce testosterone.

J. Negative-feedback loop
   1. Regulates hormone secretion by the hypothalamus and pituitary gland
   2. Increased amounts of target gland hormones in the bloodstream decrease secretion of the same hormone and other hormones that stimulate its release.

II. Diagnostic Tests
   A. Stimulation and suppression tests
      1. Stimulation tests
         a. In the client with suspected underactivity of an endocrine gland, a stimulus may be provided to determine whether the gland is capable of normal hormone production.
         b. Measured amounts of selected hormones or substances are administered to stimulate the target gland to produce its hormone.
c. Hormone levels produced by the target gland are measured.

d. Failure of the hormone level to increase with stimulation indicates hypofunction.

2. Suppression tests

a. Suppression tests are used when hormone levels are high or in the upper range of normal.

b. Agents that normally induce a suppressed response are administered to determine whether normal negative feedback is intact.

c. Failure of hormone production to be suppressed during standardized testing indicates hyperfunction.

3. Overnight dexamethasone suppression test

a. Used to distinguish between Cushing’s syndrome and Cushing’s disease.

b. In Cushing’s disease the source of excess cortisol is the pituitary gland rather than the adrenal cortex or exogenous corticosteroid administration.

c. Dexamethasone, a potent long-acting corticosteroid given at bedtime, should suppress the morning cortisol in clients without Cushing’s disease by suppressing adrenocorticotropic hormone (ACTH) production; in the client with Cushing’s disease, this suppression will not occur.

B. Radioactive iodine uptake

1. This thyroid function test measures the absorption of an iodine isotope to determine how the thyroid gland is functioning.

2. A small dose of radioactive iodine is given by mouth or intravenously; the amount of radioactivity is measured in 2 to 4 hours and again at 24 hours.

3. Normal values are approximately 3% to 10% at 2 to 4 hours, and 5% to 30% in 24 hours.

4. Elevated values indicate hyperthyroidism, decreased iodine intake, or increased iodine excretion.

5. Decreased values indicate a low T4 level, the use of antithyroid medications, thyroiditis, myxedema, or hypothyroidism.

6. The test is contraindicated in pregnancy.
C. T₃ and T₄ resin uptake test

1. Blood tests are used to diagnose thyroid disorders.
2. T₃ and T₄ regulate thyroid-stimulating hormone.
3. Normal values (normal findings vary between laboratory settings)
   a. Triiodothyronine, total T₃: 110.4 to 337.7 ng/dL (1.7 to 5.2 pmol/L)
   b. Thyroxine, total T₄: 5 to 12 mcg/dL (64 to 154 nmol/L)
   c. Thyroxine, free (FT₄): 0.8 to 2.8 ng/dL (10 to 36 pmol/L)
4. The T₄ level is elevated in hyperthyroidism and decreased in hypothyroidism.

D. Thyroid-stimulating hormone

1. Blood test is used to differentiate the diagnosis of primary hypothyroidism.
2. Normal value is 2 to 10 mclU/mL (2 to 10 mIU/L).
3. Elevated values indicate primary hypothyroidism.
4. Decreased values indicate hyperthyroidism or secondary hypothyroidism.

E. Thyroid scan

1. A thyroid scan is performed to identify nodules or growths in the thyroid gland.
2. A radioisotope of iodine or technetium is administered before scanning the thyroid gland.
3. Reassure the client that the level of radioactive medication is not dangerous to self or others.
4. Determine whether the client has received radiographic contrast agents within the past 3 months, because these may invalidate the scan.
5. Check with the primary health care provider (PHCP) regarding discontinuing medications containing iodine for 14 days before the test and the need to discontinue thyroid medication before the test.
6. Instruct the client to maintain NPO (nothing by mouth) status after midnight on the day before the test; if iodine is used, the client will fast for an additional 45 minutes after ingestion of the oral isotope and the scan will be performed in 24 hours.
7. If technetium is used, it is administered by the intravenous (IV) route 30 minutes before the scan.
8. The test is contraindicated in pregnancy.

F. Needle aspiration of thyroid tissue
   1. Aspiration of thyroid tissue is done for cytological examination.
   2. No client preparation is necessary; NPO status may or may not be prescribed.
   3. Light pressure is applied to the aspiration site after the procedure.

G. Glycosylated hemoglobin
   1. HgbA1c is blood glucose bound to hemoglobin.
   2. **Hemoglobin A1c** (glycosylated hemoglobin A; HbA1c) is a reflection of how well blood glucose levels have been controlled for the past 3 to 4 months.
   3. **Hyperglycemia** in clients with diabetes is usually a cause of an increase in HbA1c.
   4. Fasting is not required before the test.
   5. Normal reference intervals: <6% (adult without diabetes)
   6. HgbA1c and estimated average glucose (eAG) reference intervals: Refer to Table 10-4 for these reference intervals.

Poor glycemic control in a client with diabetes mellitus is usually the cause of an increase in the HbA1c value.

H. 24-hour urine collection for vanillylmandelic acid (VMA)
   1. Diagnostic tests for pheochromocytoma include a 24-hour urine collection for VMA, a product of catecholamine metabolism, metanephrine, and catecholamines, all of which are elevated in the presence of pheochromocytoma.
   2. The normal range of urinary catecholamines:
      a. Epinephrine: less than 20 mcg/day (less than 109 nmol/day)
      b. Norepinephrine: less than 100 mcg/day (less than 590 nmol/day)

III. Pituitary Gland Problems (Box 46-6)
   A. Hypopituitarism
      1. Description: Hyposcretion of 1 or more of the pituitary hormones caused by tumors, trauma, encephalitis, autoimmunity, or stroke
      2. Hormones most often affected are growth hormone (GH) and gonadotrophic hormones (luteinizing hormone, follicle-stimulating hormone), but thyroid-stimulating hormone (TSH), adrenocorticotropic...
hormone (ACTH), or antidiuretic hormone (ADH) may be involved.

3. Assessment
   a. Mild to moderate obesity (GH, TSH)
   b. Reduced cardiac output (GH, ADH)
   c. Infertility, sexual dysfunction (gonadotropins, ACTH)
   d. Fatigue, low blood pressure (TSH, ADH, ACTH, GH)
   e. Tumors of the pituitary also may cause headaches and visual defects (the pituitary is located near the optic nerve).

4. Interventions
   a. Client may need hormone replacement for the specific deficient hormones.
   b. Provide emotional support to the client and family.
   c. Encourage the client and family to express feelings related to disturbed body image or sexual dysfunction.
   d. Client education is needed regarding the signs and symptoms of hypofunction and hyperfunction related to insufficient or excess hormone replacement.

B. Hyperpituitarism (acromegaly)
   1. Description: Hypersecretion of growth hormone by the anterior pituitary gland in an adult; caused primarily by pituitary tumors

2. Assessment
   a. Large hands and feet
   b. Thickening and protrusion of the jaw
   c. Arthritic changes and joint pain, impingement syndromes
   d. Visual disturbances
   e. Diaphoresis
   f. Oily, rough skin
   g. Organomegaly
   h. Hypertension, atherosclerosis, cardiomegaly, heart failure
   i. Dysphagia
   j. Deepening of the voice
   k. Thickening of the tongue, narrowing of
the airway, sleep apnea
l. Hyperglycemia
m. Colon polyps, increased colon cancer risk

3. Interventions

a. Provide pharmacological interventions to suppress GH or to block the action of GH
b. Prepare the client for radiation of the pituitary gland or for stereotactic radiosurgery if prescribed.
c. Prepare the client for hypophysectomy if planned.
d. Provide pharmacological and nonpharmacological interventions for joint pain.
e. Provide emotional support to the client and family, and encourage the client and family to express feelings related to disturbed body image.

C. Hypophysectomy (pituitary adenectomy, sublabial transsphenoidal pituitary surgery)

1. Description

a. Removal of a pituitary tumor via craniotomy or a sublabial transsphenoidal (endoscopic transnasal) approach (the latter approach is preferred because it is associated with fewer complications)
b. Complications for craniotomy include increased intracranial pressure, bleeding, meningitis, and hypopituitarism.
c. Complications for the sublabial transsphenoidal surgery include cerebrospinal fluid leak, infection, diabetes insipidus, and hypopituitarism.
d. If the sublabial approach is used, an incision is made along the gum line of the inner upper lip.

2. Postoperative interventions

a. Initial postoperative care is similar to craniotomy care (see Chapter 58).
b. Monitor vital signs, neurological status, and level of consciousness.
c. Elevate the head of the bed.
d. Monitor for increased intracranial pressure.
e. Instruct the client to avoid sneezing, coughing, and blowing the nose.
f. Monitor for bleeding.
g. Monitor for and report signs of temporary diabetes insipidus; monitor intake and output, and report excessive urinary output.
h. If the entire pituitary is removed, clients will require lifelong replacement of ADH, cortisol, and thyroid hormone.
i. Monitor for and report signs of infection and meningitis.
j. Administer antibiotics, analgesics, and antipyretics as prescribed.
k. Administer oral mouth rinses as prescribed. Clients may be instructed to avoid using a toothbrush or to brush teeth gently with an ultrasoft toothbrush for 10 days to 2 weeks after surgery.
l. Instruct the client in the administration of prescribed medications.

D. Diabetes insipidus

1. Description

a. Hyposcretion of ADH by the posterior pituitary gland caused by stroke, trauma, or surgery, or it may be idiopathic
b. Kidney tubules fail to reabsorb water.
c. In central diabetes insipidus there is decreased ADH production.
d. In nephrogenic diabetes insipidus, ADH production is adequate, but the kidneys do not respond appropriately.
2. Assessment

a. Excretion of large amounts of dilute urine  
b. Polydipsia  
c. Dehydration (decreased skin turgor and dry mucous membranes)  
d. Inability to concentrate urine  
e. Low urinary specific gravity; normal is 1.010 to 1.025 (1.005 to 1.030)  
f. Fatigue  
g. Muscle pain and weakness  
h. Headache  
i. Postural hypotension that may progress to vascular collapse without rehydration  
j. Tachycardia

3. Interventions

a. Monitor vital signs and neurological and cardiovascular status.  
b. Provide a safe environment, particularly for the client with postural hypotension.  
c. Monitor electrolyte values and for signs of dehydration.  
d. Maintain client intake of adequate fluids; IV hypotonic saline may be prescribed to replace urinary losses.  
e. Monitor intake and output, weight, serum osmolality, and specific gravity of urine for excessive urinary output, weight loss, and low urinary specific gravity.  
f. Instruct the client to avoid foods or liquids that produce diuresis.  
g. Vasopressin or desmopressin acetate may be prescribed; these are used when the ADH deficiency is severe or chronic.  
h. Instruct the client in the administration of medications as prescribed; desmopressin acetate may be administered by subcutaneous injection, intravenously, intranasally, or orally; watch for signs of water
intoxication indicating overtreatment.
i. Instruct the client to wear a MedicAlert bracelet.

E. Syndrome of inappropriate antidiuretic hormone secretion (SIADH)

1. Description
   a. Condition of hyperfunctioning of the posterior pituitary gland in which excess ADH is released, but not in response to the body’s need for it
   b. Causes include trauma, stroke, malignancies (often in the lungs or pancreas), medications, and stress.
   c. The syndrome results in increased intravascular volume, water intoxication, and dilutional hyponatremia.
   d. May cause cerebral edema, and the client is at risk for seizures.

2. Assessment
   a. Signs of fluid volume overload
   b. Changes in level of consciousness and mental status changes
   c. Weight gain without edema
   d. Hypertension
   e. Tachycardia
   f. Anorexia, nausea, and vomiting
   g. Hyponatremia
   h. Low urinary output and concentrated urine

3. Interventions
   a. Monitor vital signs and cardiac and neurological status.
   b. Provide a safe environment, particularly for the client with changes in level of consciousness or mental status.
   c. Monitor for signs of increased intracranial pressure.
   d. Implement seizure precautions.
   e. Elevate the head of the bed a maximum of 10 degrees to promote venous return and decrease baroreceptor-induced ADH release.
f. Monitor intake and output and obtain weight daily.
g. Monitor fluid and electrolyte balance.
h. Monitor serum and urine osmolality.
i. Restrict fluid intake as prescribed.
j. Administer IV fluids (usually normal saline [NS] or hypertonic saline) as prescribed; monitor IV fluids carefully because of the risk for fluid volume overload.
k. Loop diuretics may be prescribed to promote diuresis, but only if serum sodium is at least 125 mEq/L (125 mmol/L); potassium replacement may be necessary if loop diuretics are prescribed.
l. Vasopressin antagonists may be prescribed to decrease the renal response to ADH.

IV. Adrenal Gland Problems (Box 46-7)

A. Adrenal cortex insufficiency (Addison’s disease)

1. Primary adrenal insufficiency
   a. Also known as Addison’s disease, refers to hyposcretion of adrenal cortex hormones (glucocorticoids, mineralocorticoids, and androgen); autoimmune destruction is a common cause.
   b. Requires lifelong replacement of glucocorticoids and possibly of mineralocorticoids if significant hyposecretion occurs; the condition is fatal if left untreated.

2. Secondary adrenal insufficiency is caused by hyposcretion of ACTH from the anterior pituitary gland; mineralocorticoid release is spared.

3. Loss of glucocorticoids in Addison’s disease leads to decreased vascular tone, decreased vascular response to the catecholamines epinephrine and norepinephrine, and decreased gluconeogenesis.

4. In Addison’s disease, loss of the mineralocorticoid aldosterone leads to dehydration, hypotension, hyponatremia, and hyperkalemia.

5. Assessment (Table 46-1)

6. Interventions
a. Monitor vital signs (particularly for hypotension), for weight loss, and intake and output.
b. Monitor white blood cell (WBC) count; blood glucose; and potassium, sodium, and calcium levels.
c. Administer glucocorticoid and/or mineralocorticoid medications as prescribed.
d. Observe for addisonian crisis caused by stress, infection, trauma, or surgery.

7. Client education
   a. Need for lifelong glucocorticoid replacement and possibly lifelong mineralocorticoid replacement.
   b. Corticosteroid replacement will need to be increased during times of stress.
   c. Avoid individuals with an infection.
   d. Avoid strenuous exercise and stressful situations.
   e. Avoid over-the-counter medications.
   f. Diet should be high in protein and carbohydrates; clients taking glucocorticoids should be prescribed calcium and vitamin D supplements to maintain normal levels and to protect against corticosteroid-induced osteoporosis; some clients taking mineralocorticoids may be prescribed a diet high in sodium.
   g. Wear a MedicAlert bracelet.
   h. Report signs and symptoms of complications, such as underreplacement and overreplacement of corticosteroid hormones.

B. Addisonian crisis
   1. Description (Box 46-8)
   2. Assessment
      a. Severe headache
      b. Severe abdominal, leg, and lower back pain
      c. Generalized weakness
      d. Irritability and confusion
      e. Severe hypotension
      f. Shock
   3. Interventions
a. Prepare to administer glucocorticoids intravenously as prescribed.
b. Administer IV fluids as prescribed to replace fluids and restore electrolyte balance.
c. Following resolution of the crisis, administer glucocorticoid and mineralocorticoid orally as prescribed.
d. Monitor vital signs, particularly blood pressure.
e. Monitor neurological status, noting irritability and confusion.
f. Monitor intake and output.
g. Monitor laboratory values, particularly sodium, potassium, and blood glucose levels.
h. Protect the client from infection.
i. Maintain bed rest and provide a quiet environment.

Clients taking exogenous corticosteroids must establish a plan with their PHCPs or endocrinologist for increasing their corticosteroids during times of stress.

C. Cushing’s syndrome and Cushing’s disease (hypercortisolism)

1. Cushing’s syndrome
   a. A metabolic disorder resulting from the chronic and excessive production of cortisol by the adrenal cortex or from the administration of glucocorticoids in large doses for several weeks or longer (exogenous or iatrogenic).
   b. ACTH secreting tumors (most often of the lung, pancreas, or gastrointestinal [GI] tract) can cause Cushing’s syndrome.

2. Cushing’s disease is a metabolic disorder characterized by abnormally increased secretion (endogenous) of cortisol, caused by increased amounts of ACTH secreted by the pituitary gland.

3. Assessment (Fig. 46-2; see Table 46-1)

4. Interventions
a. Monitor vital signs, particularly blood pressure.
b. Monitor intake and output and weight.
c. Monitor laboratory values, particularly WBC count and serum glucose, sodium, potassium, and calcium levels.
d. Prepare the client for radiation as prescribed if the condition results from a pituitary adenoma.
e. Administer chemotherapeutic agents as prescribed for inoperable adrenal tumors.
f. Prepare the client for removal of the pituitary tumor (hypophysectomy, sublabial transsphenoidal adenectomy) if the condition results from increased pituitary secretion of ACTH.
g. Prepare the client for adrenalectomy if the condition results from an adrenal adenoma; glucocorticoid replacement may be required following adrenalectomy.
h. Clients requiring lifelong glucocorticoid replacement following adrenalectomy should obtain instructions from their PHCPs about increasing their glucocorticoid during times of stress.
i. Assess for and protect against postoperative thrombus formation; Cushing’s syndrome predisposes to thromboemboli.
j. Allow the client to discuss feelings related to body appearance.
k. Instruct the client about the need to wear a MedicAlert bracelet.

Addison’s disease is characterized by the hyposecretion of adrenal cortex hormones, whereas Cushing’s syndrome and Cushing’s disease are characterized by a hypersecretion of glucocorticoids.

D. Primary hyperaldosteronism (Conn’s syndrome)
   1. Description
      a. Hypersecretion of mineralocorticoids (aldosterone) from the adrenal cortex of the adrenal gland
      b. Most commonly caused by an adenoma
c. Excess secretion of aldosterone causes sodium and water retention and potassium excretion, leading to hypertension and hypokalemic alkalosis.

2. Assessment
   a. Symptoms related to hypokalemia, hypernatremia, and hypertension
   b. Headache, fatigue, muscle weakness
   c. Cardiac dysrhythmias
   d. Paresthesias, tetany
   e. Visual changes
   f. Glucose intolerance
   g. Elevated serum aldosterone levels

3. Interventions
   a. Monitor vital signs, particularly blood pressure.
   b. Monitor potassium and sodium levels.
   c. Monitor intake and output and urine for specific gravity.
   d. Monitor for hyperkalemia, particularly for clients with impaired renal function or excessive potassium intake, because potassium-retaining diuretics and aldosterone antagonists may be prescribed to promote fluid balance and control hypertension.
   e. Administer potassium supplements as prescribed to treat hypokalemia; clients taking potassium-retaining diuretics and potassium supplementation are at risk for hyperkalemia.
   f. Prepare the client for adrenalectomy.
   g. Maintain sodium restriction, if prescribed, preoperatively.
   h. Administer glucocorticoids preoperatively, as prescribed, to prevent adrenal hypofunction and prepare for stress of surgery.
   i. Monitor the client for adrenal insufficiency postoperatively.
   j. Instruct the client regarding the need for glucocorticoid therapy following adrenalectomy.
   k. Instruct the client about the need to wear a MedicAlert bracelet.

E. Pheochromocytoma
1. Description
   a. Catecholamine-producing tumor usually found in the adrenal medulla, but extraadrenal locations include the chest, bladder, abdomen, and brain; typically is a benign tumor but can be malignant.
   b. Excessive amounts of epinephrine and norepinephrine are secreted.
   c. Diagnostic test includes a 24-hour urine collection for VMA.
   d. Surgical removal of the adrenal gland is the primary treatment.
   e. Symptomatic treatment is initiated if surgical removal is not possible.
   f. The complications associated with pheochromocytoma include hypertensive crisis; hypertensive retinopathy and nephropathy, cardiac enlargement, and dysrhythmias; heart failure; myocardial infarction; increased platelet aggregation; and stroke.
   g. Death can occur from shock, stroke, renal failure, dysrhythmias, or dissecting aortic aneurysm.

2. Assessment
   a. Paroxysmal or sustained hypertension
   b. Severe headaches
   c. Palpitations
   d. Flushing and profuse diaphoresis
   e. Pain in the chest or abdomen with nausea and vomiting
   f. Heat intolerance
   g. Weight loss
   h. Tremors
   i. Hyperglycemia

3. Interventions
   a. Monitor vital signs, particularly blood pressure and heart rate.
   b. Monitor for hypertensive crisis; monitor for complications that can occur with hypertensive crisis, such as stroke, cardiac dysrhythmias, and myocardial
c. Instruct the client not to smoke, drink caffeine-containing beverages, or change position suddenly.
d. Prepare to administer α-adrenergic blocking agents and β-adrenergic blocking agents as prescribed to control hypertension. α-Adrenergic blocking agents are started 7 to 10 days before β-adrenergic blocking agents.
e. Monitor serum glucose level.
f. Promote rest and a nonstressful environment.
g. Provide a diet high in calories, vitamins, and minerals.
h. Prepare the client for adrenalectomy.

For the client with pheochromocytoma, avoid stimuli that can precipitate a hypertensive crisis, such as increased abdominal pressure and vigorous abdominal palpation.

F. Adrenalectomy

1. Description (Box 46-9)
2. Preoperative interventions
   a. Monitor electrolyte levels and correct electrolyte imbalances.
   b. Assess for dysrhythmias.
   c. Monitor for hyperglycemia.
   d. Protect the client from infections.
   e. Administer glucocorticoids as prescribed.
3. Postoperative interventions
   a. Monitor vital signs.
   b. Monitor intake and output; if the urinary output is lower than 30 mL/hr, notify the PHCP or nephrologist, because this may result in acute kidney injury and indicate impending shock.
   c. Monitor weight daily.
   d. Monitor electrolyte and serum glucose levels.
   e. Monitor for signs of hemorrhage and shock, particularly during the first 24
to 48 hours.
f. Monitor for manifestations of adrenal insufficiency (see Table 46-1).
g. Assess the dressing for drainage.
h. Monitor for paralytic ileus.
i. Administer IV fluids as prescribed to maintain blood volume.
j. Administer glucocorticoids and mineralocorticoids as prescribed.
k. Administer pain medication as prescribed.
l. Provide pulmonary interventions to prevent atelectasis (coughing and deep breathing, incentive spirometry, splinting of incision).
m. Instruct the client in the importance of hormone replacement therapy following surgery.
n. Instruct the client regarding signs and symptoms of complications such as underreplacement and overreplacement of hormones.
o. Instruct the client regarding the need to wear a MedicAlert bracelet.

V. Thyroid Gland Problems

A. Hypothyroidism

1. Description

   a. Hypothyroid state resulting from hyposecretion of thyroid hormones and characterized by a decreased rate of body metabolism
   b. The T4 is low and the TSH is elevated.
   c. In primary hypothyroidism, the source of dysfunction is the thyroid gland, and the thyroid cannot produce the necessary amount of hormones. In secondary hypothyroidism, the thyroid is not being stimulated by the pituitary to produce hormones.

2. Assessment (Table 46-2)

3. Interventions

   a. Monitor vital signs, including heart rate
and rhythm.
b. Administer thyroid replacement; levothyroxine sodium is most commonly prescribed.
c. Instruct the client about thyroid replacement therapy and about the clinical manifestations of both hypothyroidism and hyperthyroidism related to underreplacement or overreplacement of the hormone.
d. Instruct the client in a low-calorie, low-cholesterol, low–saturated fat diet; discuss a daily exercise program such as walking.
e. Assess the client for constipation; provide roughage and fluids to prevent constipation.
f. Provide a warm environment for the client.
g. Avoid sedatives and opioid analgesics because of increased sensitivity to these medications; may precipitate myxedema coma.
h. Monitor for overdose of thyroid medications, characterized by tachycardia, chest pain, restlessness, nervousness, and insomnia.
i. Instruct the client to report episodes of chest pain or other signs of overdose immediately.

B. Myxedema coma

1. Description (Box 46-10)
2. Assessment
   a. Hypotension
   b. Bradycardia
   c. Hypothermia
   d. Hyponatremia
   e. Hypoglycemia
   f. Generalized edema
   g. Respiratory failure
   h. Coma
3. Interventions
   a. Maintain a patent airway.
   b. Institute aspiration precautions.
   c. Administer IV fluids (normal or hypertonic saline) as prescribed.
   d. Administer levothyroxine sodium
intravenously as prescribed.
e. Administer glucose intravenously as prescribed.
f. Administer corticosteroids as prescribed.
g. Assess the client’s temperature hourly.
h. Monitor blood pressure frequently.
i. Keep the client warm.
j. Monitor for changes in mental status.
k. Monitor electrolyte and glucose levels.

C. Hyperthyroidism

1. Description
   a. Hyperthyroid state resulting from hypersecretion of thyroid hormones (T₃ and T₄)
   b. Characterized by an increased rate of body metabolism
   c. A common cause is Graves’ disease, also known as toxic diffuse goiter.
   d. Clinical manifestations are referred to as thyrotoxicosis.
   e. The T₃ and T₄ are usually elevated and the TSH level is low.

2. Assessment (see Table 46-2; Fig. 46-3)

3. Interventions
   a. Provide adequate rest.
b. Administer sedatives as prescribed.
c. Provide a cool and quiet environment.
d. Obtain weight daily.
e. Provide a high-calorie diet.
f. Avoid the administration of stimulants.
g. Administer antithyroid medications, such as methimazole or propylthiouracil, that block thyroid synthesis as prescribed.
h. Administer iodine preparations that inhibit the release of thyroid hormone as prescribed.
i. Administer propranolol for tachycardia as prescribed.
j. Prepare the client for radioactive iodine therapy, as prescribed, to destroy thyroid cells.
k. Prepare the client for subtotal
thyroidectomy if prescribed.

1. Elevate the head of the bed of a client experiencing exophthalmos; in addition, instruct on low-salt diet, administer artificial tears, encourage the use of dark glasses, and tape eyelids closed at night if necessary.

m. Allow the client to express concerns about body image changes.

D. Thyroid storm

1. Description (Box 46-11)

2. Assessment

   a. Elevated temperature (fever)
   b. Tachycardia
   c. Systolic hypertension
   d. Nausea, vomiting, and diarrhea
   e. Agitation, tremors, anxiety
   f. Irritability, agitation, restlessness, confusion, and seizures as the condition progresses
   g. Delirium and coma

3. Interventions

   a. Maintain a patent airway and adequate ventilation.
   b. Administer antithyroid medications, iodides, propranolol, and glucocorticoids as prescribed.
   c. Monitor vital signs.
   d. Monitor continually for cardiac dysrhythmias.
   e. Administer nonsalicylate antipyretics as prescribed (salicylates increase free thyroid hormone levels).
   f. Use a cooling blanket to decrease temperature as prescribed.

E. Thyroidectomy

1. Description

   a. Removal of the thyroid gland
   b. Performed when persistent hyperthyroidism exists
   c. Subtotal thyroidectomy, removal of a portion of the thyroid gland, is the preferred surgical intervention.

2. Preoperative interventions

   a. Obtain vital signs and weight.
3. Postoperative interventions

a. Monitor for respiratory distress.
b. Have a tracheotomy set, oxygen, and suction at the bedside.
c. Limit client talking, and assess level of hoarseness.
d. Avoid neck flexion and stress on the suture line.
e. Monitor for laryngeal nerve damage, as evidenced by airway obstruction, dysphonia, high-pitched voice, stridor, dysphagia, and restlessness.
f. Monitor for signs of hypocalcemia and tetany, which can be caused by trauma to the parathyroid gland (Box 46-12).
g. Prepare to administer calcium gluconate as prescribed for tetany.
h. Monitor for thyroid storm.

VI. Parathyroid Gland Problems

A. Hypoparathyroidism

1. Description

a. Condition caused by hyposecretion of parathyroid hormone by the parathyroid gland
b. Can occur following thyroidectomy
because of removal of parathyroid tissue

2. Assessment

a. Hypocalcemia and hyperphosphatemia
b. Numbness and tingling in the face
c. Muscle cramps and cramps in the abdomen or in the extremities
d. Positive Trousseau’s sign or Chvostek’s sign
e. Signs of overt tetany, such as bronchospasm, laryngospasm, carpopedal spasm, dysphagia, photophobia, cardiac dysrhythmias, seizures
f. Hypotension
g. Anxiety, irritability, depression

3. Interventions

a. Monitor vital signs.
b. Monitor for signs of hypocalcemia and tetany.
c. Initiate seizure precautions.
d. Place a tracheotomy set, oxygen, and suctioning equipment at the bedside.
e. Prepare to administer calcium gluconate intravenously for hypocalcemia.
f. Provide a high-calcium, low-phosphorus diet.
g. Instruct the client in the administration of calcium supplements as prescribed.
h. Instruct the client in the administration of vitamin D supplements as prescribed; vitamin D enhances the absorption of calcium from the gastrointestinal (GI) tract.
i. Instruct the client in the use of thiazide diuretics if prescribed, to protect the kidney if vitamin D is also taken.
j. Instruct the client in the administration of phosphate binders as prescribed to promote the excretion of phosphate through the GI tract.
k. Instruct the client to wear a MedicAlert bracelet.

B. Hyperparathyroidism
1. Description: Condition caused by hypersecretion of parathyroid hormone (PTH) by the parathyroid gland

2. Assessment

   - a. Hypercalcemia and hypophosphatemia
   - b. Fatigue and muscle weakness
   - c. Skeletal pain and tenderness
   - d. Bone deformities that result in pathological fractures
   - e. Anorexia, nausea, vomiting, epigastric pain
   - f. Weight loss
   - g. Constipation
   - h. Hypertension
   - i. Cardiac dysrhythmias
   - j. Renal stones

3. Interventions

   - a. Monitor vital signs, particularly blood pressure.
   - b. Monitor for cardiac dysrhythmias.
   - c. Monitor intake and output and for signs of renal stones.
   - d. Monitor for skeletal pain; move the client slowly and carefully.
   - e. Encourage fluid intake.
   - f. Administer furosemide as prescribed to lower calcium levels.
   - g. Administer NS intravenously as prescribed to maintain hydration.
   - h. Administer phosphates, which interfere with calcium reabsorption, as prescribed.
   - i. Administer calcitoning as prescribed to decrease skeletal calcium release and increase renal excretion of calcium.
   - j. Administer IV or oral bisphosphonates to inhibit bone resorption.
   - k. Monitor calcium and phosphorus levels.
   - l. Prepare the client for parathyroidectomy as prescribed.
   - m. Encourage a high-fiber, moderate-calcium diet.
   - n. Emphasize the importance of an
exercise program and avoiding prolonged inactivity.

C. Parathyroidectomy

1. Description: Removal of 1 or more of the parathyroid glands

   a. Endoscopic radioguided parathyroidectomy with autotransplantation is a common procedure.
   b. Parathyroid tissue is transplanted in the forearm or near the sternocleidomastoid muscle, allowing PTH secretion to continue.

2. Preoperative interventions

   a. Monitor electrolytes, calcium, phosphate, and magnesium levels.
   b. Ensure that calcium levels are decreased to near-normal values.
   c. Inform the client that talking may be painful for the first day or two after surgery.

3. Postoperative interventions

   a. Monitor for respiratory distress.
   b. Place a tracheotomy set, oxygen, and suctioning equipment at the bedside.
   c. Monitor vital signs.
   d. Position the client in semi-Fowler’s position.
   e. Assess neck dressing for bleeding.
   f. Monitor for hypocalcemic crisis, as evidenced by tingling and twitching in the extremities and face.
   g. Assess for positive Trousseau’s sign or Chvostek’s sign, which indicates tetany.
   h. Monitor for changes in voice pattern and hoarseness.
   i. Monitor for laryngeal nerve damage.
   j. Instruct the client in the administration of calcium and vitamin D supplements as prescribed.

VII. Problems of the Pancreas

A. Diabetes mellitus

1. Description

   a. Chronic disorder of impaired
carbohydrate, protein, and lipid metabolism caused by a deficiency of insulin

b. An absolute or relative deficiency of insulin results in hyperglycemia.

c. Type 1 diabetes mellitus is a nearly absolute deficiency of insulin (primary beta cell destruction); if insulin is not given, fats are metabolized for energy, resulting in ketonemia (acidosis).

d. Type 2 diabetes mellitus is a relative lack of insulin or resistance to the action of insulin; usually, insulin is sufficient to stabilize fat and protein metabolism but not carbohydrate metabolism.

e. Metabolic syndrome is also known as syndrome X, and the individual has coexisting risk factors for developing type 2 diabetes mellitus; these risk factors include abdominal obesity, hyperglycemia, hypertension, high triglyceride level, and a lowered HDL (high-density lipoprotein) cholesterol level.

f. Diabetes mellitus can lead to chronic health problems and early death as a result of complications that occur in the large and small blood vessels in tissues and organs.

g. Macrovascular complications include coronary artery disease, cardiomyopathy, hypertension, cerebrovascular disease, and peripheral vascular disease. (Refer to Chapter 52 for information on cardiovascular problems.)

h. Microvascular complications include retinopathy, nephropathy, and neuropathy.

i. Infection is also a concern because of reduced healing ability.

j. Male erectile dysfunction can also occur as a result of the disease.

⚠️ Obesity is a major risk factor for diabetes
2. Assessment

a. Polyuria, polydipsia, polyphagia (more common in type 1 diabetes mellitus)
b. Hyperglycemia
c. Weight loss (common in type 1 diabetes mellitus, rare in type 2 diabetes mellitus)
d. Blurred vision
e. Slow wound healing
f. Vaginal infections
g. Weakness and paresthesias
h. Signs of inadequate circulation to the feet
i. Signs of accelerated atherosclerosis (renal, cerebral, cardiac, peripheral)

3. Diet

a. The diabetic client’s diet should take into account weight, medication, activity level, and other health problems.
b. Day-to-day consistency in timing and amount of food intake helps control the blood glucose level.
c. As prescribed by the PHCP or endocrinologist, the client may be advised to follow the recommendations of the American Diabetic Association diet or U.S. dietary guidelines (MyPlate; http://www.choosemyplate.gov/) issued by the U.S. Departments of Agriculture and Health and Human Services.
d. Carbohydrate counting may be a simpler approach for some clients; it focuses on the total grams of carbohydrates eaten per meal. The client may be more compliant with carbohydrate counting, resulting in better glycemic control; it is usually necessary for clients undergoing intense insulin therapy.
e. Incorporate the diet into individual client needs, lifestyle, and cultural and socioeconomic patterns.
4. Exercise

a. Exercise lowers the blood glucose level, encourages weight loss, reduces cardiovascular risks, improves circulation and muscle tone, decreases total cholesterol and triglyceride levels, and decreases insulin resistance and glucose intolerance.

b. Instruct the client in dietary adjustments when exercising; dietary adjustments are individualized.

c. If the client requires extra food during exercise to prevent hypoglycemia, it need not be deducted from the regular meal plan.

d. If the blood glucose level is higher than 250 mg/dL (13.9 mmol/L) and urinary ketones (type 1 diabetes mellitus) are present, the client is instructed not to exercise until the blood glucose level is closer to normal and urinary ketones are absent.

e. The client should try to exercise at the same time each day and should exercise when glucose from the meal is peaking, not when insulin or glucose-lowering medications are peaking.

f. Insulin should not be injected into an area of the body that will be exercised following injection, as exercise speeds absorption.

5. Oral hypoglycemic medications: Oral medications are prescribed for clients with diabetes mellitus type 2 when diet and weight control therapy have failed to maintain satisfactory blood glucose levels (Chapter 47).

6. Insulin (refer to Chapter 47 for additional information on insulin)

a. Insulin is used to treat type 1 diabetes
mellitus and may be used to treat type 2 diabetes mellitus when diet, weight control therapy, and oral hypoglycemic agents have failed to maintain satisfactory blood glucose levels.

b. Illness, infection, and stress increase the blood glucose level and the need for insulin; insulin should not be withheld during times of illness, infection, or stress because hyperglycemia and diabetic ketoacidosis can result.

c. The peak action time of insulin is important to explain to the client because of the possibility of hypoglycemic reactions occurring during this time.

Regular insulin (U-100 strength) can be administered via IV injection (IV push). Regular insulin (U-100) and the short-duration insulins (lispro, aspart, and glulisine) can be administered via IV infusion.

B. Complications of insulin therapy

1. Local allergic reactions

a. Redness, swelling, tenderness, and induration or a wheal at the site of injection may occur 1 to 2 hours after administration.

b. Reactions usually occur during the early stages of insulin therapy.

c. Instruct the client to cleanse the skin with alcohol before injection.

2. Insulin lipodystrophy

a. The development of fibrous fatty masses at the injection site caused by repeated use of an injection site; use of human insulin helps prevent this.

b. Instruct the client to avoid injecting insulin into affected sites.

c. Instruct the client about the importance of rotating insulin injection sites. Systematic rotation within 1 anatomical area is recommended to
prevent lipodystrophy; the client should be instructed not to use the same site more than once in a 2- to 3-week period. Injections should be 1.5 inches (3.8 cm) apart within the anatomical area.

3. **Dawn phenomenon**
   a. Dawn phenomenon is characterized by hyperglycemia upon morning awakening that results from excessive early morning release of GH and cortisol.
   b. Treatment requires an increase in the client’s insulin dose or a change in the time of insulin administration.

4. **Somogyi phenomenon**
   a. Normal or elevated blood glucose levels are present at bedtime; hypoglycemia occurs at about 2 to 3 a.m., which causes an increase in the production of counterregulatory hormones.
   b. By about 7 a.m., in response to the counterregulatory hormones, the blood glucose rebounds significantly to the hyperglycemic range.
   c. Treatment includes a decrease in the client’s insulin dose or increase in the bedtime snack, or both.
   d. Clients experiencing the Somogyi phenomenon may complain of early morning headaches, night sweats, or nightmares caused by the early morning hypoglycemia.

C. Insulin administration

1. Subcutaneous injections and mixing insulin: See Chapter 47.
2. Insulin pumps
   a. Continuous subcutaneous insulin infusion is administered by an externally worn device that contains a syringe and pump; different types of pumps are available and the one selected is based on the client’s needs.
   b. The client inserts the needle or Teflon catheter into the subcutaneous tissue (usually on the abdomen or upper arm) and secures it with tape or a
transparent dressing; the needle or Teflon catheter is changed at least every 2 to 3 days.

c. A continuous basal rate of insulin infuses; in addition, on the basis of the blood glucose level, the anticipated food intake, and the activity level, the client delivers a bolus of insulin before each meal.

d. Both rapid-acting and regular short-acting insulin (buffered to prevent the precipitation of insulin crystals within the catheter) are appropriate for use in these pumps.

3. Insulin pump and skin sensor
a. A skin sensor device can be used that monitors the client’s blood glucose continuously; the information is transmitted to the pump, which determines the need for insulin, and then the insulin is injected.

b. The pump holds up to a 3-day supply of insulin and can be disconnected easily if necessary for certain activities such as bathing.

4. Pancreas transplants
a. The goal of pancreatic transplantation is to halt or reverse the complications of diabetes mellitus.

b. Transplantations are performed on a limited number of clients (in general, these are clients who are undergoing kidney transplantation simultaneously).

c. Immunosuppressive therapy is prescribed to prevent and treat rejection.

D. Self-monitoring of blood glucose level

1. Self-monitoring provides the client with the current blood glucose level and information to maintain good glycemic control.

2. Monitoring requires a finger prick to obtain a drop of blood for testing.

3. Alternative site testing (obtaining blood from the forearm, upper arm, abdomen, thigh, or calf) is available, using specific measurement devices.

4. Tests must be used with caution in clients with
diabetic neuropathy.

5. Client instructions (Box 46-13)

E. Urine testing

1. Urine testing for glucose is not a reliable indicator of the blood glucose level and is not used for monitoring purposes.
2. Instruct the client in the procedure for testing for urine ketones.
3. The presence of ketones may indicate impending ketoacidosis.
4. Urine ketone testing should be performed during illness and whenever the client with type 1 diabetes mellitus has persistently elevated blood glucose levels (higher than 250 mg/dL [13.9 mmol/L] or as prescribed for 2 consecutive testing periods).

VIII. Acute Complications of Diabetes Mellitus

A. Hypoglycemia

1. Description

a. Hypoglycemia occurs when the blood glucose level falls below 70 mg/dL (3.9 mmol/L), or when the blood glucose level drops rapidly from an elevated level.

b. Hypoglycemia is caused by too much insulin or too large an amount of an oral hypoglycemic agent, too little food, or excessive activity.

c. The client needs to be instructed always to carry some form of fast-acting simple carbohydrate with him or her (Box 46-14).

d. If the client has a hypoglycemic reaction and does not have any of the recommended emergency foods available, any available food should be eaten; high-fat foods slow the absorption of glucose, and the hypoglycemic symptoms may not resolve quickly.

e. Clients who experience frequent episodes of hypoglycemia, older clients, and clients taking β-adrenergic blocking agents may not experience the warning signs of hypoglycemia until the blood glucose level is dangerously low; this phenomenon is termed hypoglycemia unawareness.
2. Assessment (Box 46-15)

a. Mild hypoglycemia: The client remains fully awake but displays adrenergic symptoms; the blood glucose level is lower than 70 mg/dL (3.9 mmol/L).

b. Moderate hypoglycemia: The client displays symptoms of worsening hypoglycemia; the blood glucose level is usually lower than 3.9 mg/dL (2.2 mmol/L).

c. Severe hypoglycemia: The client displays severe neuroglycopenic symptoms; the blood glucose level is usually lower than 20 mg/dL (1.1 mmol/L).

3. Interventions (see Priority Nursing Actions)

Priority Nursing Actions

Suspected Hypoglycemic Reaction (the 15/15 rule)

1. If a blood glucose monitor is readily available, check the client’s blood glucose level. If the client is experiencing symptoms suggestive of hypoglycemia such as diaphoresis, hunger, pallor, and shakiness, and a blood glucose monitor is not readily available, assume hypoglycemia and treat accordingly.

2. For the client whose blood glucose is below 70 mg/dL (3.9 mmol/L), or for the client with an unknown blood glucose who is exhibiting signs of hypoglycemia, administer 15 g of a simple carbohydrate such as ½ cup of fruit juice or 15 g of glucose gel.

3. Recheck the blood glucose level in 15 minutes.

4. If the blood glucose remains below 70 mg/dL (3.9 mmol/L), administer another 15 g of a simple carbohydrate.

5. Recheck the blood glucose level in 15 minutes; if still below 70 mg/dL (3.9 mmol/L), treat with an additional 15 g of a simple carbohydrate.

6. Recheck the blood glucose level in 15 minutes; if still below 70 mg/dL (3.9 mmol/L), treat with 25 to 50 mL of 50% dextrose intravenously or, if no intravenous (IV) equipment is present, treat with 1 mg of glucagon subcutaneously or intramuscularly.

7. After the blood glucose level has recovered, have the client ingest a snack that includes a complex carbohydrate and a protein.

8. Document the client’s complaints, actions taken, and outcome.

9. Explore the precipitating cause of the hypoglycemia with the client.

10. If the client is experiencing an altered level of consciousness, bypass oral treatment and start with injectable glucagon or 50% dextrose. If the client is at home and does not have access to injectable glucagon, the client should seek immediate medical care.

Reference
Do not attempt to administer oral food or fluids to the client experiencing a severe hypoglycemic reaction who is semiconscious or unconscious and is unable to swallow. This client is at risk for aspiration. For this client, an injection of glucagon is administered subcutaneously or intramuscularly. In the hospital or emergency department, the client may be treated with an IV injection of 25 to 50 mL (12.5 to 25 g) of 50% dextrose in water.

B. Diabetic ketoacidosis (DKA)

1. Description (Fig. 46-4)
   a. Diabetic ketoacidosis is a life-threatening complication of type 1 diabetes mellitus that develops when a severe insulin deficiency occurs.
   b. The main clinical manifestations include hyperglycemia, dehydration, ketosis, and acidosis.

2. Assessment (Table 46-3)

3. Interventions
   a. Restore circulating blood volume and protect against cerebral, coronary, and renal hypoperfusion.
   b. Treat dehydration with rapid IV infusions of 0.9% or 0.45% NS as prescribed; dextrose is added to IV fluids when the blood glucose level reaches 250 to 300 mg/dL (13.9 to 16.7 mmol/L). Too rapid administration of IV fluids; use of the incorrect types of IV fluids, particularly hypotonic solutions; and correcting the blood glucose level too rapidly can lead to cerebral edema.
   c. Treat hyperglycemia with insulin administered intravenously as prescribed.
   d. Correct electrolyte imbalances (potassium level may be elevated as a result of dehydration and acidosis).
e. Monitor potassium level closely, because when the client receives treatment for the dehydration and acidosis, the serum potassium level will decrease and potassium replacement may be required.

f. Cardiac monitoring should be in place for the client with DKA due to risks associated with abnormal serum potassium levels.

4. Insulin IV administration

a. Use short-duration insulin only.

b. An IV bolus dose of short-duration regular U-100 insulin (usually 5 to 10 units) may be prescribed before a continuous infusion is begun.

c. The prescribed IV dose of insulin for continuous infusion is prepared in 0.9% or 0.45% NS as prescribed.

d. Always place the insulin infusion on an IV infusion controller.

e. Insulin is infused continuously until subcutaneous administration resumes, to prevent a rebound of the blood glucose level.

f. Monitor vital signs.

g. Monitor urinary output and monitor for signs of fluid overload.

h. Monitor potassium and glucose levels and for signs of increased intracranial pressure.

i. The potassium level will fall rapidly within the first hour of treatment as the dehydration and the acidosis are treated.

j. Potassium is administered intravenously in a diluted solution as prescribed; ensure adequate renal function before administering potassium.

5. Client education (Box 46-16)

Monitor the client being treated for DKA closely for signs of increased intracranial pressure. If the blood glucose level falls too far or too fast before the brain has time to equilibrate, water is pulled from the blood to the cerebrospinal fluid and the brain, causing cerebral edema and increased intracranial pressure.
C. Hyperosmolar hyperglycemic syndrome (HHS)

1. Description
   a. Extreme hyperglycemia occurs without ketosis or acidosis.
   b. The syndrome occurs most often in individuals with type 2 diabetes mellitus.
   c. The major difference between HHS and DKA is that ketosis and acidosis do not occur with HHS; enough insulin is present with HHS to prevent the breakdown of fats for energy, thus preventing ketosis.

2. Assessment (see Table 46-3)

3. Interventions
   a. Treatment is similar to that for DKA.
   b. Treatment includes fluid replacement, correction of electrolyte imbalances, and insulin administration.
   c. Fluid replacement in the older client must be done very carefully because of the potential for heart failure.
   d. Insulin plays a less critical role in the treatment of HHS than it does in the treatment of DKA because ketosis and acidosis do not occur; rehydration alone may decrease glucose levels.

IX. Chronic Complications of Diabetes Mellitus

A. Diabetic retinopathy

1. Description
   a. Chronic and progressive impairment of the retinal circulation that eventually causes hemorrhage
   b. Permanent vision changes and blindness can occur.
   c. The client has difficulty with carrying out the daily tasks of blood glucose testing and insulin injections.

2. Assessment
   a. A change in vision is caused by the rupture of small microaneurysms in retinal blood vessels.
   b. Blurred vision results from macular...
edema.
c. Sudden loss of vision results from retinal detachment.
d. Cataracts result from lens opacity.

3. Interventions
   a. Maintain safety.
   b. Early prevention via the control of hypertension and blood glucose levels
   c. Photocoagulation (laser therapy) may be done to remove hemorrhagic tissue to decrease scarring and prevent progression of the disease process.
   d. Vitrectomy may be done to remove vitreous hemorrhages and thus decrease tension on the retina, preventing detachment.
   e. Cataract removal with lens implantation improves vision.

B. Diabetic nephropathy

1. Description: Progressive decrease in kidney function

2. Assessment
   a. Microalbuminuria
   b. Thirst
   c. Fatigue
   d. Anemia
   e. Weight loss
   f. Signs of malnutrition
   g. Frequent urinary tract infections
   h. Signs of a neurogenic bladder

3. Interventions
   a. Early prevention measures include the control of hypertension and blood glucose levels.
   b. Assess vital signs.
   c. Monitor intake and output.
   d. Monitor the blood urea nitrogen, creatinine, and urine albumin levels.
   e. Restrict dietary protein, sodium, and potassium intake as prescribed.
   f. Avoid nephrotoxic medications.
   g. Prepare the client for dialysis procedures if planned.
   h. Prepare the client for kidney transplant if planned.
i. Prepare the client for pancreas transplant if planned.

C. Diabetic neuropathy

1. Description

a. General deterioration of the nervous system throughout the body

b. Complications include the development of nonhealing ulcers of the feet, gastric paresis, and erectile dysfunction.

2. Classifications

a. Focal neuropathy or mononeuropathy: Involves a single nerve or group of nerves, most frequently cranial nerves III (oculomotor) and VI (abducens), resulting in diplopia

b. Sensory or peripheral neuropathy: Affects distal portion of nerves, most frequently in the lower extremities

c. Autonomic neuropathy: Symptoms vary according to the organ system involved.

d. Cardiovascular: Cardiac denervation syndrome (heart rate does not respond to changes in oxygenation needs) and orthostatic hypotension occur.

e. Pupillary: Pupil does not dilate in response to decreased light.

f. Gastric: Decreased gastric emptying (gastroparesis)

g. Urinary: Neurogenic bladder

h. Skin: Decreased sweating

i. Adrenal: Hypoglycemic unawareness

j. Reproductive: Impotence (male), painful intercourse (female)

3. Assessment: Findings depend on the classification

a. Paresthesias

b. Decreased or absent reflexes

c. Decreased sensation to vibration or light touch

d. Pain, aching, and burning in the lower extremities

e. Poor peripheral pulses

f. Skin breakdown and signs of infection
g. Weakness or loss of sensation in cranial nerves III (oculomotor), IV (trochlear), V (trigeminal), and VI (abducens)
h. Dizziness and postural hypotension
i. Nausea and vomiting
j. Diarrhea or constipation
k. Incontinence
l. Dyspareunia
m. Impotence
n. Hypoglycemic unawareness

4. Interventions
a. Early prevention measures include the control of hypertension and blood glucose levels.
b. Careful foot care is required to prevent trauma (Box 46-17).
c. Administer medications as prescribed for pain relief.
d. Initiate bladder training programs.
e. Instruct in the use of estrogen-containing lubricants for women with dyspareunia.
f. Prepare the male client with impotence for penile injections or other possible treatment options as prescribed.
g. Prepare for surgical decompression of compression lesions related to the cranial nerves as prescribed.

X. Care of the Diabetic Client Undergoing Surgery

A. Preoperative care
1. Check with PHCP regarding withholding oral hypoglycemic medications or insulin.
2. Some long-acting oral antidiabetic medications are discontinued 24 to 48 hours before surgery.
3. Metformin may need to be discontinued 48 hours before surgery and may not be restarted until renal function is normal postoperatively.
4. All other oral antidiabetic medications are usually withheld on the day of surgery.
5. Insulin dose may be adjusted or withheld if IV insulin administration during surgery is planned.
6. Monitor blood glucose level.
7. Administer IV fluids as prescribed.

B. Postoperative care
1. Administer IV glucose and insulin infusions as prescribed until the client can tolerate oral feedings.
2. Administer supplemental short-acting insulin as
prescribed based on blood glucose results.
3. Monitor blood glucose levels frequently, especially if the client is receiving parenteral nutrition.
4. When the client is tolerating food, ensure that the client receives an adequate amount of carbohydrates daily to prevent hypoglycemia.
5. Client is at higher risk for cardiovascular and renal complications postoperatively.
6. Client is also at risk for impaired wound healing.

**Box 46-1**

**Endocrine Glands**

- Adrenal
- Hypothalamus
- Ovaries
- Pancreas
- Parathyroid
- Pituitary
- Testes
- Thyroid

**Box 46-2**

**Risk Factors for Endocrine Problems**

- Age
- Heredity
- Congenital factors
- Trauma
- Environmental factors
- Consequence of other health problems or surgery

**Box 46-3**

**Hypothalamus Hormones**

- Corticotropin-releasing hormone (CRH)
- Gonadotropin-releasing hormone (GnRH)
- Growth hormone–inhibiting hormone (GHIH)
**Box 46-4**

**Pituitary Gland Hormones**

**Anterior Lobe Production**

- Adrenocorticotropic hormone (ACTH)
- Follicle-stimulating hormone (FSH)
- Growth hormone (GH)
- Luteinizing hormone (LH)
- Melanocyte-stimulating hormone (MSH)
- Prolactin (PRL)
- Somatotropic growth-stimulating hormone
- Thyroid-stimulating hormone (TSH)

**Posterior Lobe**

These hormones are produced by the hypothalamus, stored in the posterior lobe, and secreted into the blood when needed:

- Oxytocin
- Vasopressin, antidiuretic hormone (ADH)

*FIG. 46-1* Pituitary hormones. *FSH*, Follicle-stimulating hormone; *LH*, luteinizing hormone.
Box 46-5

Adrenal Cortex

Glucocorticoids: Cortisol, Cortisone, Corticosterone
Responsible for glucose metabolism, protein metabolism, fluid and electrolyte balance, suppression of the inflammatory response to injury, protective immune response to invasion by infectious agents, and resistance to stress

Mineralocorticoids: Aldosterone
Regulation of electrolyte balance by promoting sodium retention and potassium excretion

Box 46-6

Pituitary Gland Problems

Anterior Pituitary

▪ Hyperpituitarism
▪ Hypopituitarism

Posterior Pituitary

These problems can be caused by damage to the posterior pituitary or hypothalamus:

▪ Diabetes insipidus
▪ Syndrome of inappropriate antidiuretic hormone secretion (SIADH)

Box 46-7

Adrenal Gland Problems

Adrenal Cortex

▪ Addison’s disease
▪ Primary hyperaldosteronism (Conn’s syndrome)
▪ Cushing’s disease
▪ Cushing’s syndrome
Adrenal Medulla

- Pheochromocytoma

### Box 46-8

**Addisonian Crisis**

- A life-threatening disorder caused by acute adrenal insufficiency
- Precipitated by stress, infection, trauma, surgery, or abrupt withdrawal of exogenous corticosteroid use
- Can cause hyponatremia, hyperkalemia, hypoglycemia, and shock
Typical appearance of a client with Cushing’s syndrome. Note truncal obesity, moon face, buffalo hump, thinner arms and legs, and abdominal striae. (From Wenig, Heffess, Adair, 1997.)

### Box 46-9

**Adrenalectomy**

- Surgical removal of an adrenal gland
- Lifelong glucocorticoid and mineralocorticoid replacement is necessary with bilateral adrenalectomy.
- Temporary glucocorticoid replacement, usually up to 2 years, is necessary after a unilateral adrenalectomy.
- Catecholamine levels drop as a result of surgery, which can result in cardiovascular collapse, hypotension, and shock, and the client needs to be monitored closely.
- Hemorrhage also can occur because of the high vascularity of the adrenal glands.

**Box 46-10**

**Myxedema Coma**

- This rare but serious disorder results from persistently low thyroid production.
- Coma can be precipitated by acute illness, rapid withdrawal of thyroid medication, anesthesia and surgery, hypothermia, or the use of sedatives and opioid analgesics.
Box 46-11

Thyroid Storm

- This acute and life-threatening condition occurs in a client with uncontrollable hyperthyroidism.
- It can be caused by manipulation of the thyroid gland during surgery and the release of thyroid hormone into the bloodstream; it also can occur from severe infection and stress.
- Antithyroid medications, beta blockers, glucocorticoids, and iodides may be administered to the client before thyroid surgery to prevent its occurrence.
**Box 46-12**

**Signs of Tetany**

- Cardiac dysrhythmias
- Carpopedal spasm
- Dysphagia
- Muscle and abdominal cramps
- Numbness and tingling of the face and extremities
- Positive Chvostek’s sign
- Positive Trousseau’s sign
- Visual disturbances (photophobia)
- Wheezing and dyspnea (bronchospasm, laryngospasm)
- Seizures

**Box 46-13**

**Client Instructions: Self-Monitoring of Blood Glucose Level**

- Use the proper procedure to obtain the sample for determining the blood glucose level.
- Perform the procedure precisely to obtain accurate results.
- Follow the manufacturer’s instructions for the glucometer.
- Wash hands before and after performing the procedure to prevent infection.
- If needed, calibrate the monitor as instructed by the manufacturer.
- Check the expiration date on the test strips.
- If the blood glucose level results do not seem reasonable, reread the instructions, reassess technique, check the expiration date of the test strips, and perform the procedure again to verify results.

**Box 46-14**

**Simple Carbohydrates to Treat Hypoglycemia**

- Commercially prepared glucose tablets or glucose gel
- 6 to 10 Life Savers or hard candy
- 4 tsp of sugar
- 4 sugar cubes
- 1 Tbsp of honey or syrup
• ½ cup of fruit juice or regular (nondiet) soft drink
• 8 oz (235 mL) of low-fat milk
• 6 saltine crackers
• 3 graham crackers

Box 46-15
Assessment of Hypoglycemia

Mild

• Hunger
• Nervousness
• Palpitations
• Sweating
• Tachycardia
• Tremor

Moderate

• Confusion
• Double vision
• Drowsiness
• Emotional changes
• Headache
• Impaired coordination
• Inability to concentrate
• Irrational or combative behavior
• Lightheadedness
• Numbness of the lips and tongue
• Slurred speech

Severe

• Difficulty arousing
• Disoriented behavior
• Loss of consciousness
• Seizures

---

**Box 46-16**

**Client Education: Guidelines During Illness**

- Take insulin or oral antidiabetic medications as prescribed.
- Determine the blood glucose level and test the urine for ketones every 3 to 4 hours.
- If the usual meal plan cannot be followed, substitute soft foods 6 to 8 times a day.
- If vomiting, diarrhea, or fever occurs, consume liquids every 30 to 60 minutes to prevent dehydration and to provide calories.
- Notify the primary health care provider if vomiting, diarrhea, or fever persists; if blood glucose levels are higher than 250 to 300 mg/dL (13.9 to 16.7 mmol/L); when ketonuria is present for more than 24 hours; when unable to take food or fluids for a period of 4 hours; or when illness persists for more than 2 days.

---

**Box 46-17**

**Preventive Foot Care Instructions**
- Provide meticulous skin care and proper foot care.
- Inspect feet daily and monitor feet for redness, swelling, or break in skin integrity.
- Notify the primary health care provider if redness or a break in the skin occurs.
- Avoid thermal injuries from hot water, heating pads, and baths.
- Wash feet with warm (not hot) water and dry thoroughly (avoid foot soaks).
- Avoid treating corns, blisters, or ingrown toenails.
- Do not cross legs or wear tight garments that may constrict blood flow.
- Apply moisturizing lotion to the feet but not between the toes.
- Prevent moisture from accumulating between the toes.
- Wear loose socks and well-fitting (not tight) shoes; do not go barefoot.
- Wear clean cotton socks to keep the feet warm and change the socks daily.
- Avoid wearing the same pair of shoes 2 days in a row.
- Avoid wearing open-toed shoes or shoes with a strap that goes between the toes.
- Check shoes for cracks or tears in the lining and for foreign objects before putting them on.
- Break in new shoes gradually.
- Cut toenails straight across and smooth nails with an emery board.
- Avoid smoking.
- Follow-up with podiatry referral and recommendations as needed.

Practice Questions

487. A client is brought to the emergency department in an unresponsive state, and a diagnosis of hyperosmolar hyperglycemic syndrome is made. The nurse would immediately prepare to initiate which anticipated primary health care provider’s prescription?
   1. Endotracheal intubation
   2. 100 units of NPH insulin
   3. Intravenous infusion of normal saline
   4. Intravenous infusion of sodium bicarbonate

488. An external insulin pump is prescribed for a client with diabetes mellitus. When the client asks the nurse about the functioning of the pump, the nurse bases the response on which information about the pump?
   1. It is timed to release programmed doses of either short-duration or NPH insulin into the bloodstream at specific intervals.
   2. It continuously infuses small amounts of NPH insulin into the bloodstream while regularly monitoring blood glucose levels.
   3. It is surgically attached to the pancreas and infuses regular insulin into the pancreas. This releases insulin into the bloodstream.
   4. It administers a small continuous dose of short-duration insulin subcutaneously. The client can self-administer an additional bolus dose from the pump before each meal.

489. A client with a diagnosis of diabetic ketoacidosis (DKA) is being treated in
the emergency department. Which findings support this diagnosis? Select all that apply.

1. Increase in pH
2. Comatose state
3. Deep, rapid breathing
4. Decreased urine output
5. Elevated blood glucose level

490. The nurse teaches a client with diabetes mellitus about differentiating between hypoglycemia and ketoacidosis. The client demonstrates an understanding of the teaching by stating that a form of glucose should be taken if which symptoms develop? Select all that apply.

1. Polyuria
2. Shakiness
3. Palpitations
4. Blurred vision
5. Lightheadedness
6. Fruity breath odor

491. A client with diabetes mellitus demonstrates acute anxiety when admitted to the hospital for the treatment of hyperglycemia. What is the appropriate intervention to decrease the client’s anxiety?

1. Administer a sedative.
2. Convey empathy, trust, and respect toward the client.
3. Ignore the signs and symptoms of anxiety, anticipating that they will soon disappear.
4. Make sure that the client is familiar with the correct medical terms to promote understanding of what is happening.

492. The nurse provides instructions to a client newly diagnosed with type 1 diabetes mellitus. The nurse recognizes accurate understanding of measures to prevent diabetic ketoacidosis when the client makes which statement?

1. “I will stop taking my insulin if I’m too sick to eat.”
2. “I will decrease my insulin dose during times of illness.”
3. “I will adjust my insulin dose according to the level of glucose in my urine.”
4. “I will notify my primary health care provider (PHCP) if my blood glucose level is higher than 250 mg/dL (13.9 mmol/L).”

493. A client is admitted to a hospital with a diagnosis of diabetic ketoacidosis (DKA). The initial blood glucose level is 950 mg/dL (52.9 mmol/L). A continuous intravenous (IV) infusion of short-acting insulin is initiated, along with IV rehydration with normal saline. The serum glucose level is now decreased to 240 mg/dL (13.3 mmol/L). The nurse would next prepare to administer which medication?

1. An ampule of 50% dextrose
2. NPH insulin subcutaneously
3. IV fluids containing dextrose
4. Phenytoin for the prevention of seizures

494. The nurse is monitoring a client newly diagnosed with diabetes mellitus for signs of complications. Which sign or symptom, if frequently exhibited in the client, indicates that the client is at risk for chronic complications of diabetes if the blood glucose is not adequately managed?
   1. Polyuria
   2. Diaphoresis
   3. Pedal edema
   4. Decreased respiratory rate

495. The nurse is preparing a plan of care for a client with diabetes mellitus who has hyperglycemia. The nurse places priority on which client problem?
   1. Lack of knowledge
   2. Inadequate fluid volume
   3. Compromised family coping
   4. Inadequate consumption of nutrients

496. The home health nurse visits a client with a diagnosis of type 1 diabetes mellitus. The client reports a history of vomiting and diarrhea and tells the nurse that no food has been consumed for the last 24 hours. Which additional statement by the client indicates a need for further teaching?
   1. “I need to stop my insulin.”
   2. “I need to increase my fluid intake.”
   3. “I need to monitor my blood glucose every 3 to 4 hours.”
   4. “I need to call my primary health care provider (PHCP) because of these symptoms.”

497. The nurse is caring for a client after hypophysectomy and notes clear nasal drainage from the client’s nostril. The nurse should take which initial action?
   1. Lower the head of the bed.
   2. Test the drainage for glucose.
   3. Obtain a culture of the drainage.
   4. Continue to observe the drainage.

498. The nurse is admitting a client who is diagnosed with syndrome of inappropriate antidiuretic hormone secretion (SIADH) and has serum sodium of 118 mEq/L (118 mmol/L). Which primary health care provider prescriptions should the nurse anticipate receiving? Select all that apply.
   1. Initiate an infusion of 3% NaCl.
   2. Administer intravenous furosemide.
   3. Restrict fluids to 800 mL over 24 hours.
   4. Elevate the head of the bed to high-Fowler’s.
   5. Administer a vasopressin antagonist as prescribed.

499. A client is admitted to an emergency department, and a diagnosis of myxedema coma is made. Which action should the nurse prepare to carry out initially?
   1. Warm the client.
2. Maintain a patent airway.
3. Administer thyroid hormone.

500. The nurse is caring for a client admitted to the emergency department with diabetic ketoacidosis (DKA). In the acute phase, the nurse plans for which priority intervention?
   1. Correct the acidosis.
   2. Administer 5% dextrose intravenously.
   3. Apply a monitor for an electrocardiogram.
   4. Administer short-duration insulin intravenously.

501. A client with type 1 diabetes mellitus who takes NPH daily in the morning calls the nurse to report recurrent episodes of hypoglycemia with exercising. Which statement by the client indicates an adequate understanding of the peak action of NPH insulin and exercise?
   1. “I should not exercise since I am taking insulin.”
   2. “The best time for me to exercise is after breakfast.”
   3. “The best time for me to exercise is mid- to late afternoon.”
   4. “NPH is a basal insulin, so I should exercise in the evening.”

502. The nurse is completing an assessment on a client who is being admitted for a diagnostic workup for primary hyperparathyroidism. Which client complaints would be characteristic of this disorder? Select all that apply.
   1. Polyuria
   2. Headache
   3. Bone pain
   4. Nervousness
   5. Weight gain

503. The nurse is teaching a client with hyperparathyroidism how to manage the condition at home. Which response by the client indicates the need for additional teaching?
   1. “I should consume less than 1 liter of fluid per day.”
   2. “I should use my treadmill or go for walks daily.”
   3. “I should follow a moderate-calcium, high-fiber diet.”
   4. “My alendronate helps keep calcium from coming out of my bones.”

504. A client with a diagnosis of addisonian crisis is being admitted to the intensive care unit. Which findings will the interprofessional health care team focus on? Select all that apply.
   1. Hypotension
   2. Leukocytosis
   3. Hyperkalemia
   4. Hypocalcemia
   5. Hyponatremia
505. The nurse is monitoring a client who was diagnosed with type 1 diabetes mellitus and is being treated with NPH and regular insulin. Which manifestations would alert the nurse to the presence of a possible hypoglycemic reaction? Select all that apply.

- 1. Tremors
- 2. Anorexia
- 3. Irritability
- 4. Nervousness
- 5. Hot, dry skin
- 6. Muscle cramps

506. The nurse is performing an assessment on a client with pheochromocytoma. Which assessment data would indicate a potential complication associated with this disorder?

- 1. A urinary output of 50 mL/hr
- 2. A coagulation time of 5 minutes
- 3. A heart rate that is 90 beats per minute and irregular
- 4. A blood urea nitrogen level of 20 mg/dL (7.1 mmol/L)

507. The nurse is monitoring a client diagnosed with acromegaly who was treated with transsphenoidal hypophysectomy and is recovering in the intensive care unit. Which findings should alert the nurse to the presence of a possible postoperative complication? Select all that apply.

- 1. Anxiety
- 2. Leukocytosis
- 3. Chvostek’s sign
- 4. Urinary output of 800 mL/hr
- 5. Clear drainage on nasal dripper pad

508. The nurse performs a physical assessment on a client with type 2 diabetes mellitus. Findings include a fasting blood glucose level of 70 mg/dL (3.9 mmol/L), temperature of 101°F (38.3°C), pulse of 82 beats per minute, respirations of 20 breaths per minute, and blood pressure of 118/68 mm Hg. Which finding would be the priority concern to the nurse?

- 1. Pulse
- 2. Respiration
- 3. Temperature
- 4. Blood pressure

509. The nurse is preparing a client with a new diagnosis of hypothyroidism for discharge. The nurse determines that the client understands discharge instructions if the client states that which signs and symptoms are associated with this diagnosis? Select all that apply.

- 1. Tremors
2. Weight loss
3. Feeling cold
4. Loss of body hair
5. Persistent lethargy
6. Puffiness of the face

510. A client has just been admitted to the nursing unit following thyroidectomy. Which assessment is the priority for this client?
1. Hoarseness
2. Hypocalcemia
3. Audible stridor
4. Edema at the surgical site

511. A client has been diagnosed with hyperthyroidism. The nurse monitors for which signs and symptoms indicating a complication of this disorder? Select all that apply.
1. Fever
2. Nausea
3. Lethargy
4. Tremors
5. Confusion
6. Bradycardia

**Answers**

487. **Answer:** 3

**Rationale:** The primary goal of treatment in hyperosmolar hyperglycemic syndrome (HHS) is to rehydrate the client to restore fluid volume and to correct electrolyte deficiency. Intravenous (IV) fluid replacement is similar to that administered in diabetic ketoacidosis (DKA) and begins with IV infusion of normal saline. Regular insulin, not NPH insulin, would be administered. The use of sodium bicarbonate to correct acidosis is avoided because it can precipitate a further drop in serum potassium levels. Intubation and mechanical ventilation are not required to treat HHS.

**Test-Taking Strategy:** Focus on the subject, treatment of HHS, and note the strategic word, immediately. If you can recall the treatment for DKA, you will be able to answer this question easily. Treatment for HHS is similar to the treatment for DKA and begins with rehydration.

**Level of Cognitive Ability:** Analyzing
**Client Needs:** Physiological Integrity
**Integrated Process:** Nursing Process—Planning
Rationale: An insulin pump provides a small continuous dose of short-duration (rapid- or short-acting) insulin subcutaneously throughout the day and night. The client can self-administer an additional bolus dose from the pump before each meal as needed. Short-duration insulin is used in an insulin pump. An external pump is not attached surgically to the pancreas.

Test-Taking Strategy: Focus on the subject, use of an insulin pump. Recalling that short-duration insulin is used in an insulin pump will assist in eliminating options 1 and 2. Noting the word external in the question will assist in eliminating option 3.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Adult Health: Endocrine
Health Problem: Adult Health: Endocrine: Diabetes Mellitus
Priority Concepts: Client Education; Glucose Regulation

489. Answer: 2, 3, 5

Rationale: Because of the profound deficiency of insulin associated with DKA, glucose cannot be used for energy and the body breaks down fat as a secondary source of energy. Ketones, which are acid by-products of fat metabolism, build up, and the client experiences a metabolic ketoacidosis. High serum glucose contributes to an osmotic diuresis and the client becomes severely dehydrated. If untreated, the client will become comatose due to severe dehydration, acidosis, and electrolyte imbalance. Kussmaul’s respirations, the deep rapid breathing associated with DKA, is a compensatory mechanism by the body. The body attempts to correct the acidotic state by blowing off carbon dioxide (CO\textsubscript{2}), which is an acid. In the absence of insulin, the client will experience severe hyperglycemia. Option 1 is incorrect, because in acidosis the pH would be low. Option 4 is incorrect because a high serum glucose will result in an osmotic diuresis and the client will experience polyuria.

Test-Taking Strategy: Focus on the subject, findings associated with DKA. Recall that the pathophysiology of DKA is the breakdown of fats for energy. The breakdown of fats leads to a state of acidosis. The high serum glucose contributes to an osmotic diuresis. Knowing the pathophysiology of DKA will aid in identification of the correct answers.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Endocrine
Health Problem: Adult Health: Endocrine: Diabetes Mellitus
**Priority Concepts:** Clinical Judgment; Glucose Regulation

**Reference:** Lewis et al. (2017), pp. 1143-1145.

490. Answer: 2, 3, 5

**Rationale:** Shakiness, palpitations, and lightheadedness are signs/symptoms of hypoglycemia and would indicate the need for food or glucose. Polyuria, blurred vision, and a fruity breath odor are manifestations of hyperglycemia.

**Test-Taking Strategy:** Focus on the subject, the treatment of hypoglycemia. Think about its pathophysiology and the manifestations that occur. Recalling the signs and symptoms of hypoglycemia will direct you to the correct option.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Evaluation

**Content Area:** Adult Health: Endocrine

**Health Problem:** Adult Health: Endocrine: Diabetes Mellitus

**Priority Concepts:** Client Education; Glucose Regulation

491. Answer: 2

**Rationale:** Anxiety is a subjective feeling of apprehension, uneasiness, or dread. The appropriate intervention is to address the client’s feelings related to the anxiety. Administering a sedative is not the most appropriate intervention and does not address the source of the client’s anxiety. The nurse should not ignore the client’s anxious feelings. Anxiety needs to be managed before meaningful client education can occur.

**Test-Taking Strategy:** Use therapeutic communication techniques to answer the question. Remember that the client’s feelings are the priority. Keeping this in mind will direct you easily to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Caring

**Content Area:** Adult Health: Endocrine

**Health Problem:** Adult Health: Endocrine: Diabetes Mellitus

**Priority Concepts:** Anxiety; Caregiving

**References:** Lewis et al. (2017), pp. 302-303; Potter et al. (2017), pp. 327-329.

492. Answer: 4

**Rationale:** During illness, the client with type 1 diabetes mellitus is at increased risk of diabetic ketoacidosis, due to hyperglycemia associated with the stress response and due to a typically decreased caloric intake. As part of sick day management, the client with diabetes should monitor blood glucose levels and should notify the PHCP if the level is higher than 250 mg/dL (13.9 mmol/L). Insulin should never be stopped. In fact, insulin may need to be increased during times of illness. Doses should not be adjusted without the PHCP’s advice and are usually...
adjusted on the basis of blood glucose levels, not urinary glucose readings.

**Test-Taking Strategy:** Use general medication guidelines to answer the question. Note that options 1, 2, and 3 are **comparable or alike** and all relate to adjustment of insulin doses.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Adult Health: Endocrine  
**Health Problem:** Adult Health: Endocrine: Diabetes Mellitus  
**Priority Concepts:** Client Education; Glucose Regulation  

493. **Answer:** 3

**Rationale:** Emergency management of DKA focuses on correcting fluid and electrolyte imbalances and normalizing the serum glucose level. If the corrections occur too quickly, serious consequences, including hypoglycemia and cerebral edema, can occur. During management of DKA, when the blood glucose level falls to 250 to 300 mg/dL (13.9 to 16.7 mmol/L), the IV infusion rate is reduced and a dextrose solution is added to maintain a blood glucose level of about 250 mg/dL (13.9 mmol/L), or until the client recovers from ketosis. Fifty percent dextrose is used to treat hypoglycemia. NPH insulin is not used to treat DKA. Phenytoin is not a usual treatment measure for DKA.

**Test-Taking Strategy:** Note the **strategic word,** next. Focus on the **subject,** management of DKA. Eliminate option 2 first, knowing that short-duration (rapid-acting) insulin is used in the management of DKA. Eliminate option 1 next, knowing that this is the treatment for hypoglycemia. Note the words the serum glucose level is now decreased to 240 mg/dL (13.3 mmol/L). This should indicate that the IV solution containing dextrose is the next step in the management of care.

**Level of Cognitive Ability:** Synthesizing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Adult Health: Endocrine  
**Health Problem:** Adult Health: Endocrine: Diabetes Mellitus  
**Priority Concepts:** Clinical Judgment; Glucose Regulation  

494. **Answer:** 1

**Rationale:** Chronic hyperglycemia, resulting from poor glycemic control, contributes to the microvascular and macrovascular complications of diabetes mellitus. Classic symptoms of hyperglycemia include polydipsia, polyuria, and polyphagia. Diaphoresis may occur in hypoglycemia. Hypoglycemia is an acute complication of diabetes mellitus; however, it does not predispose a client to the chronic complications of diabetes mellitus. Therefore, option 2 can be eliminated because this finding is characteristic of hypoglycemia. Options 3 and 4 are not associated with diabetes mellitus.
**Test-Taking Strategy:** Focus on the **subject**, chronic complications of diabetes mellitus. Recall that poor glycemic control contributes to development of the chronic complications of diabetes mellitus. Remember the 3 Ps associated with hyperglycemia—polyuria, polydipsia, and polyphagia.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Analysis  
**Content Area:** Adult Health: Endocrine  
**Health Problem:** Adult Health: Endocrine: Diabetes Mellitus  
**Priority Concepts:** Clinical Judgment; Glucose Regulation  

495. **Answer:** 2

**Rationale:** An increased blood glucose level will cause the kidneys to excrete the glucose in the urine. This glucose is accompanied by fluids and electrolytes, causing an osmotic diuresis leading to dehydration. This fluid loss must be replaced when it becomes severe. Options 1, 3, and 4 are not related specifically to the information in the question.

**Test-Taking Strategy:** Note the **strategic word**, *priority*, and focus on the information in the question. Use Maslow’s Hierarchy of Needs theory. The correct option indicates a physiological need and is the priority. Options 1, 3, and 4 are problems that may need to be addressed after providing for the priority physiological needs.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Adult Health: Endocrine  
**Health Problem:** Adult Health: Endocrine: Diabetes Mellitus  
**Priority Concepts:** Clinical Judgment; Glucose Regulation  
**Reference:** Lewis et al. (2017), p. 1143.

496. **Answer:** 1

**Rationale:** When a client with diabetes mellitus is unable to eat normally because of illness, the client still should take the prescribed insulin or oral medication. The client should consume additional fluids and should notify the PHCP. The client should monitor the blood glucose level every 3 to 4 hours. The client should also monitor the urine for ketones during illness.

**Test-Taking Strategy:** Note the **strategic words**, need for further teaching. These words indicate a negative event query and the need to select the incorrect statement. Remembering that the client needs to take insulin will direct you easily to the correct option.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Endocrine

1432
**Health Problem:** Adult Health: Endocrine: Diabetes Mellitus

**Priority Concepts:** Client Education; Glucose Regulation

497. **Answer:** 2

**Rationale:** After hypophysectomy, the client should be monitored for rhinorrhea, which could indicate a cerebrospinal fluid leak. If this occurs, the drainage should be collected and tested for the presence of cerebrospinal fluid. Cerebrospinal fluid contains glucose, and if positive, this would indicate that the drainage is cerebrospinal fluid. The head of the bed should remain elevated to prevent increased intracranial pressure. Clear nasal drainage would not indicate the need for a culture. Continuing to observe the drainage without taking action could result in a serious complication.

**Test-Taking Strategy:** Note the strategic word, initial, and determine whether an abnormality exists. This indicates that an action is required. Option 1 can be eliminated first by recalling that this action can increase intracranial pressure. Option 3 can be eliminated also, because the drainage is clear. Because an action is required, eliminate option 4.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Adult Health: Endocrine

**Health Problem:** Adult Health: Endocrine: Pituitary Disorders

**Priority Concepts:** Clinical Judgment; Intracranial Regulation

498. **Answer:** 1, 3, 5

**Rationale:** Clients with SIADH experience excess secretion of antidiuretic hormone (ADH), which leads to excess intravascular volume, a declining serum osmolarity, and dilutional hyponatremia. Management is directed at correcting the hyponatremia and preventing cerebral edema. Hypertonic saline is prescribed when the hyponatremia is severe, less than 120 mEq/L (120 mmol/L). An intravenous (IV) infusion of 3% saline is hypertonic. Hypertonic saline must be infused slowly as prescribed, and an infusion pump must be used. Fluid restriction is a useful strategy aimed at correcting dilutional hyponatremia. Vasopressin is an ADH; vasopressin antagonists are used to treat SIADH. Furosemide may be used to treat extravascular volume and dilutional hyponatremia in SIADH, but it is only safe to use if the serum sodium is at least 125 mEq/L (125 mmol/L). When furosemide is used, potassium supplementation should also occur and serum potassium levels should be monitored. To promote venous return, the head of the bed should not be raised more than 10 degrees for the client with SIADH. Maximizing venous return helps avoid stimulating stretch receptors in the heart that signal to the pituitary that more ADH is needed.

**Test-Taking Strategy:** Focus on the subject, treatment for SIADH. Think about the pathophysiology associated with SIADH. Remember that SIADH is associated with
the increased secretion of ADH, or vasopressin. Excess vasopressin leads to increased intravascular fluid volume, decreased serum osmolality, and hyponatremia. When hyponatremia and decreased serum osmolality become severe, cerebral edema occurs.

**Priority Concepts:** Clinical Judgment; Fluids and Electrolytes  

499. **Answer:** 2

**Rationale:** Myxedema coma is a rare but serious disorder that results from persistently low thyroid production. Coma can be precipitated by acute illness, rapid withdrawal of thyroid medication, anesthesia and surgery, hypothermia, and the use of sedatives and opioid analgesics. In myxedema coma, the initial nursing action is to maintain a patent airway. Oxygen should be administered, followed by fluid replacement, keeping the client warm, monitoring vital signs, and administering thyroid hormones by the intravenous route.

**Test-Taking Strategy:** Note the strategic word, *initially.* All the options are appropriate interventions, but use the ABCs—airway, breathing, and circulation—in selecting the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Adult Health: Endocrine  
**Health Problem:** Adult Health: Endocrine: Thyroid Disorders  
**Priority Concepts:** Gas Exchange; Thermoregulation  

500. **Answer:** 4

**Rationale:** Lack of insulin (absolute or relative) is the primary cause of DKA. Treatment consists of insulin administration (short- or rapid-acting), intravenous fluid administration (normal saline initially, not 5% dextrose), and potassium replacement, followed by correcting acidosis. Cardiac monitoring is important due to alterations in potassium levels associated with DKA and its treatment, but applying an electrocardiogram monitor is not the priority action.

**Test-Taking Strategy:** Focus on the client’s diagnosis. Note the strategic word, *priority.* Remember that in DKA, the initial treatment is short- or rapid-acting insulin. Normal saline is administered initially; therefore, option 2 is incorrect. Options 1 and 3 may be components of the treatment plan but are not the priority.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation
**Rationale:** Exercise is an important part of diabetes management. It promotes weight loss, decreases insulin resistance, and helps control blood glucose levels. A hypoglycemic reaction may occur in response to increased exercise, so clients should exercise either an hour after mealtime or after consuming a 10- to 15-g carbohydrate snack, and they should check their blood glucose level before exercising. Option 1 is incorrect because clients with diabetes should exercise, though they should check with their primary health care provider before starting a new exercise program. Option 3 is incorrect; clients should avoid exercise during the peak time of insulin. NPH insulin peaks at 4 to 12 hours; therefore, afternoon exercise takes place during the peak of the medication. Option 4 is incorrect; NPH insulin is an intermediate-acting insulin, not a basal insulin.

**Test-Taking Strategy:** Focus on the subject, peak action of NPH insulin. Recalling that NPH insulin peaks at 4 to 12 hours and that exercise is beneficial for clients with diabetes will direct you to the correct option.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Evaluation

---

**Rationale:** The role of parathyroid hormone (PTH) in the body is to maintain serum calcium homeostasis. In hyperparathyroidism, PTH levels are high, which causes bone resorption (calcium is pulled from the bones). Hypercalcemia occurs with hyperparathyroidism. Elevated serum calcium levels produce osmotic diuresis and thus polyuria. This diuresis leads to dehydration (weight loss rather than weight gain). Loss of calcium from the bones causes bone pain. Options 2, 4, and 5 are not associated with hyperparathyroidism. Some gastrointestinal symptoms include anorexia, nausea, vomiting, and constipation.

**Test-Taking Strategy:** Focus on the subject, assessment findings in hyperparathyroidism. Think about the pathophysiology associated with hyperparathyroidism. Remember that hypercalcemia is associated with this disorder and that hypercalcemia leads to diuresis, and that calcium loss from bone leads to bone pain.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment
Rationale: In hyperparathyroidism, clients experience excess parathyroid hormone (PTH) secretion. A role of PTH in the body is to maintain serum calcium homeostasis. When PTH levels are high, there is excess bone resorption (calcium is pulled from the bones). In clients with elevated serum calcium levels, there is a risk of nephrolithiasis. One to two liters of fluids daily should be encouraged to protect the kidneys and decrease the risk of nephrolithiasis. Moderate physical activity, particularly weight-bearing activity, minimizes bone resorption and helps protect against pathological fracture. Walking, as an exercise, should be encouraged in the client with hyperparathyroidism. Even though serum calcium is already high, clients should follow a moderate-calcium diet, because a low-calcium diet will surge PTH. Calcium causes constipation, so a diet high in fiber is recommended. Alendronate is a bisphosphate that inhibits bone resorption. In bone resorption, bone is broken down and calcium is deposited into the serum.

Test-Taking Strategy: Note the strategic words, need for additional teaching. These words indicate a negative event query and the need to select the incorrect statement. Consider the pathophysiology of hyperparathyroidism. Hyperparathyroidism leads to bone demineralization, which places the client at risk for pathological fracture, and high serum calcium, which places the client at risk for nephrolithiasis. Knowing that fluids should be encouraged rather than limited to help prevent nephrolithiasis should direct you to the correct option.

Health Problem: Adult Health: Endocrine: Parathyroid Disorders
Priority Concepts: Client Education; Fluids and Electrolytes
by holding salt and water and excreting potassium. When there is insufficient aldosterone, salt and water are lost and potassium builds up; this leads to hypotension from decreased vascular volume, hyponatremia, and hyperkalemia. The remaining options are not associated with addisonian crisis.

**Test-Taking Strategy:** Focus on the subject, addisonian crisis. Think about the pathophysiology associated with Addison’s disease. Recalling that in Addison’s disease there is a decrease in the glucocorticoid cortisol and the mineralocorticoid aldosterone will assist in determining the correct answer.

**Content Area:** Adult Health: Endocrine

**Health Problem:** Adult Health: Endocrine: Adrenal Disorders

**Priority Concepts:** Clinical Judgment; Fluids and Electrolytes

505. **Answer:** 1, 3, 4

**Rationale:** Decreased blood glucose levels produce autonomic nervous system symptoms, which are manifested classically as nervousness, irritability, and tremors. Option 5 is more likely to occur with hyperglycemia. Options 2 and 6 are unrelated to the manifestations of hypoglycemia. In hypoglycemia, usually the client feels hunger.

**Test-Taking Strategy:** Focus on the subject, a hypoglycemic reaction. Think about the pathophysiology and manifestations that occur when the blood glucose is low. Recalling the signs of this type of reaction will direct you easily to the correct options.

**Content Area:** Adult Health: Endocrine

**Health Problem:** Adult Health: Endocrine: Diabetes Mellitus

**Priority Concepts:** Clinical Judgment; Glucose Regulation

506. **Answer:** 3

**Rationale:** Pheochromocytoma is a catecholamine-producing tumor usually found in the adrenal medulla, but extra-adrenal locations include the chest, bladder, abdomen, and brain; it is typically a benign tumor but can be malignant. Excessive amounts of epinephrine and norepinephrine are secreted. The complications associated with pheochromocytoma include hypertensive retinopathy and nephropathy, myocarditis, increased platelet aggregation, and stroke. Death can occur from shock, stroke, kidney failure, dysrhythmias, or dissecting aortic aneurysm. An irregular heart rate indicates the presence of a dysrhythmia. A coagulation time of 5 minutes is normal. A urinary output of 50 mL/hr is an adequate output. A blood urea nitrogen level of 20 mg/dL (7.1 mmol/L) is a normal
finding.

Test-Taking Strategy: Use the ABCs—airway, breathing, and circulation. An irregular heart rate is associated with circulation. In addition, knowing the normal hourly expectations associated with urinary output and the normal laboratory values for coagulation time and blood urea nitrogen level assists in selection of the correct option.

Health Problem: Adult Health: Endocrine: Adrenal Disorders
Priority Concepts: Clinical Judgment; Perfusion

507. Answer: 2, 4, 5

Rationale: Acromegaly results from excess secretion of growth hormone, usually caused by a benign tumor on the anterior pituitary gland. Treatment is surgical removal of the tumor, usually with a sublingual transsphenoidal complete or partial hypophysectomy. The sublingual transsphenoidal approach is often through an incision in the inner upper lip at the gum line. Transsphenoidal surgery is a type of brain surgery, and infection is a primary concern. Leukocytosis, or an elevated white count, may indicate infection. Diabetes insipidus is a possible complication of transsphenoidal hypophysectomy. In diabetes insipidus there is decreased secretion of antidiuretic hormone, and clients excrete large amounts of dilute urine. Following transsphenoidal surgery, the nasal passages are packed and a dripper pad is secured under the nares. Clear drainage on the dripper pad is suggestive of a cerebrospinal fluid leak. The surgeon should be notified and the drainage should be tested for glucose. A cerebrospinal fluid leak increases the postoperative risk of meningitis. Anxiety is a nonspecific finding that is common to many disorders. Chvostek’s sign is a test of nerve hyperexcitability associated with hypocalcemia and is seen as grimacing in response to tapping on the facial nerve. Chvostek’s sign has no association with complications of sublingual transsphenoidal hypophysectomy.

Test-Taking Strategy: Focus on the subject, postoperative complications of sublingual transsphenoidal hypophysectomy. Knowing that infection, diabetes insipidus, and cerebrospinal fluid leak are possible complications will assist in determining the correct answer.

Content Area: Adult Health: Endocrine
Health Problem: Adult Health: Endocrine: Pituitary Disorders
Priority Concepts: Clinical Judgment; Intracranial Regulation

508. Answer: 3
Rationale: In the client with type 2 diabetes mellitus, an elevated temperature may indicate infection. Infection is a leading cause of hyperosmolar hyperglycemic syndrome in the client with type 2 diabetes mellitus. The other findings are within normal limits.

Test-Taking Strategy: Note the strategic word, priority. Use knowledge of the normal values of vital signs to direct you to the correct option. The client’s temperature is the only abnormal value. Remember that an elevated temperature can indicate an infectious process that can lead to complications in the client with diabetes mellitus.

Health Problem: Adult Health: Endocrine: Diabetes Mellitus
Priority Concepts: Glucose Regulation; Infection

509. Answer: 3, 4, 5, 6

Rationale: Feeling cold, hair loss, lethargy, and facial puffiness are signs of hypothyroidism. Tremors and weight loss are signs of hyperthyroidism.

Test-Taking Strategy: Focus on the subject, signs and symptoms associated with hypothyroidism. Options 1 and 2 can be eliminated if you remember that in hypothyroidism there is an undersecretion of thyroid hormone that causes the metabolism to slow down.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Adult Health: Endocrine
Health Problem: Adult Health: Endocrine: Thyroid Disorders
Priority Concepts: Client Education; Clinical Judgment

510. Answer: 3

Rationale: Thyroidectomy is the removal of the thyroid gland, which is located in the anterior neck. It is very important to monitor airway status, as any swelling to the surgical site could cause respiratory distress. Although all of the options are important for the nurse to monitor, the priority nursing action is to monitor the airway.

Test-Taking Strategy: Note the strategic word, priority. Use the ABCs—airway, breathing, and circulation, to assist in directing you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment

Health Problem: Adult Health: Endocrine: Thyroid Disorders
**Priority Concepts:** Clinical Judgment; Gas Exchange

**Reference:** Lewis et al. (2017), pp. 1167-1168.

511. **Answer:** 1, 2, 4, 5

**Rationale:** Thyroid storm is an acute and life-threatening complication that occurs in a client with uncontrollable hyperthyroidism. Signs and symptoms of thyroid storm include elevated temperature (fever), nausea, and tremors. In addition, as the condition progresses, the client becomes confused. The client is restless and anxious and experiences tachycardia.

**Test-Taking Strategy:** Focus on the **subject**, signs and symptoms indicating a complication of hyperthyroidism. Recall that thyroid storm is a complication of hyperthyroidism. Options 3 and 6 can be eliminated if you remember that thyroid storm is caused by the release of thyroid hormones into the bloodstream, causing uncontrollable hyperthyroidism. Lethargy and bradycardia (think: slow down) are signs of hypothyroidism (slow metabolism).

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process — Assessment

**Content Area:** Adult Health: Endocrine

**Health Problem:** Adult Health: Endocrine: Thyroid Disorders

I. Pituitary Medications
   A. Description
      1. The anterior pituitary gland secretes growth hormone (GH), thyroid-stimulating hormone (TSH), adrenocorticotropic hormone (ACTH), prolactin, melanocyte-stimulating hormone (MSH), and gonadotropins (follicle-stimulating hormone [FSH] and luteinizing hormone [LH]).
      2. The posterior pituitary gland secretes antidiuretic hormone (vasopressin) and oxytocin.
   B. Growth hormones and related medications (Box 47-1)
      1. Uses
         a. Growth hormones are used to treat pediatric or adult growth hormone deficiency.
         b. Growth hormone receptor antagonists are used to treat acromegaly.
         c. Growth hormone–releasing factor is used to evaluate anterior pituitary function.
      2. Side and adverse effects
         a. May vary depending on the medication
         b. Development of antibodies to growth hormone
         c. Headache, muscle pain, weakness, vertigo
         d. Diarrhea, nausea, abdominal discomfort
         e. Mild hyperglycemia
         f. Hypertension
         g. Weight gain
         h. Allergic reaction (rash, swelling), pain at injection site
         i. Elevated aspartate aminotransferase
AST) and alanine aminotransferase (ALT)

3. Interventions
   a. Assess the child’s physical growth and compare growth with standards.
   b. Recommend annual bone age determinations for children receiving growth hormones.
   c. Monitor vital signs, blood glucose levels, AST and ALT levels, and thyroid function tests.
   d. Teach the client and family about the clinical manifestations of hyperglycemia, other side and adverse effects of therapy, and the importance of follow-up regarding periodic blood tests.

II. Antidiuretic Hormones
   A. Desmopressin acetate; vasopressin
   B. Description
      1. Antidiuretic hormones enhance reabsorption of water in the kidneys, promoting an antidiuretic effect and regulating fluid balance.
      2. Antidiuretic hormones are used in diabetes insipidus.
      3. Vasopressin is used less commonly than desmopressin acetate to treat diabetes insipidus; vasopressin is commonly used to treat septic shock.
   C. Side and adverse effects
      1. Flushing
      2. Headache
      3. Nausea and abdominal cramps
      4. Water intoxication
      5. Hypertension with water intoxication
      6. Nasal congestion with nasal administration
   D. Interventions
      1. Monitor weight.
      2. Monitor intake and output and urine osmolality.
      3. Monitor electrolyte levels.
      4. Monitor for signs of dehydration, indicating the need to increase the dosage.
      5. Monitor for signs of water intoxication (drowsiness, listlessness, shortness of breath, and headache), indicating the need to decrease dosage.
6. Monitor blood pressure.
7. Instruct the client in how to use the intranasal medication.
8. Instruct the client to weigh herself or himself daily to identify weight gain.
9. Instruct the client to report signs of water intoxication or symptoms of headache or shortness of breath.

III. Thyroid Hormones (Box 47-2)

A. Description

1. Thyroid hormones control the metabolic rate of tissues and accelerate heat production and oxygen consumption.
2. Thyroid hormones are used to replace the thyroid hormone deficit in conditions such as hypothyroidism and myxedema coma.
3. Thyroid hormones enhance the action of oral anticoagulants, sympathomimetics, and antidepressants and decrease the action of insulin, oral hypoglycemics, and digitalis preparations; the action of thyroid hormones is decreased by phenytoin and carbamazepine.
4. Thyroid hormones should be given at least 4 hours apart from multivitamins, aluminum hydroxide and magnesium hydroxide, simethicone, calcium carbonate, phosphate binders, bile acid sequestrants, iron, and sucralfate, because these medications decrease the absorption of thyroid replacements.

B. Side and adverse effects

1. Nausea and decreased appetite
2. Abdominal cramps and diarrhea
3. Weight loss
4. Nervousness and tremors
5. Insomnia
6. Sweating
7. Heat intolerance
8. Tachycardia, dysrhythmias, palpitations, chest pain
9. Hypertension
10. Headache
11. Toxicity: Hyperthyroidism

C. Interventions

1. Assess the client for a history of medications currently being taken.
2. Monitor vital signs.
4. Monitor triiodothyronine (T3), thyroxine (T4) and TSH levels.

5. Instruct the client to take the medication at the same time each day, in the morning without food.

6. Instruct the client in how to monitor the pulse rate.

7. Inform the client that it is important to discuss which foods to specifically avoid that may inhibit thyroid secretion based on the client’s individualized diet plan and medication regimen.

8. Advise the client to avoid over-the-counter medications.

9. Instruct the client to wear a MedicAlert bracelet.

IV. Antithyroid Medications (Box 47-3)

A. Description

1. Antithyroid medications inhibit the synthesis of thyroid hormone.

2. Antithyroid medications are used for hyperthyroidism, or Graves’ disease.

B. Side and adverse effects

1. Nausea and vomiting

2. Diarrhea

3. Drowsiness, headache, fever

4. Hypersensitivity with rash

5. Agranulocytosis with leukopenia and thrombocytopenia

6. Alopecia and hyperpigmentation

7. Toxicity: Hypothyroidism

8. Iodism: Characterized by vomiting, abdominal pain, metallic or brassy taste in the mouth, rash, and sore gums and salivary glands.

C. Interventions

1. Monitor vital signs.

2. Monitor triiodothyronine, thyroxine, and TSH levels.

4. Instruct the client to take medication with meals to avoid gastrointestinal (GI) upset.
5. Instruct the client in how to monitor the pulse rate.
6. Inform the client of side and adverse effects and when to notify the primary health care provider (PHCP).
7. Instruct the client in the signs of hypothyroidism.
8. Instruct the client regarding the importance of medication compliance and that abruptly stopping the medication could cause thyroid storm.
9. Instruct the client to monitor for signs and symptoms of thyroid storm (fever, flushed skin, confusion and behavioral changes, tachycardia, dysrhythmias, and signs of heart failure).
10. Instruct the client to monitor for signs of iodism.
11. Advise the client to consult the PHCP before eating iodized salt and iodine-rich foods.
12. Instruct the client to avoid acetylsalicylic acid and medications containing iodine.

Methimazole causes agranulocytosis. Therefore, advise the client to contact the PHCP if a fever or sore throat develops.

V. Parathyroid Medications (Box 47-4)
A. Description
1. Parathyroid hormone regulates serum calcium levels.
2. Low serum levels of calcium stimulate parathyroid hormone release.
3. Hyperparathyroidism results in a high serum calcium level and bone demineralization; medication is used to lower the serum calcium level.
4. Hypoparathyroidism results in a low serum calcium level, which increases neuromuscular excitability; treatment includes calcium and vitamin D supplements.
5. Calcium salts administered with digoxin increase the risk of digoxin toxicity.
6. Oral calcium salts reduce the absorption of tetracycline hydrochloride.
B. Interventions
1. Monitor electrolyte and calcium levels.
2. Assess for signs and symptoms of hypocalcemia and hypercalcemia.

3. Assess for symptoms of tetany in the client with hypocalcemia.

4. Assess for renal calculi in the client with hypercalcemia.

5. Instruct the client in the signs and symptoms of hypercalcemia and hypocalcemia.

6. Instruct the client to check over-the-counter medication labels for the possibility of calcium content.

7. Instruct the client receiving oral calcium supplements to maintain an adequate intake of vitamin D, because vitamin D enhances absorption of calcium.

8. Instruct the client receiving calcium regulators such as alendronate sodium to swallow the tablet whole with water at least 30 minutes before breakfast and not to lie down for at least 30 minutes.

9. Instruct the client using nasal spray of calcitonin to alternate nares.

10. Instruct the client using antihypercalcemic agents to avoid foods rich in calcium such as green, leafy vegetables; dairy products; shellfish; and soy.

11. Instruct the client not to take other medications within 1 hour of taking a calcium supplement.

12. Instruct the client to increase fluid and fiber in the diet to prevent constipation associated with calcium supplements.

VI. Corticosteroids: Mineralocorticoids
   A. Fludrocortisone acetate
   B. Description

1. Mineralocorticoids are steroid hormones that enhance the reabsorption of sodium and chloride and promote the excretion of potassium and hydrogen from the renal tubules, thereby helping maintain fluid and electrolyte balance.

2. Mineralocorticoids are used for replacement therapy in primary and secondary adrenal insufficiency in Addison’s disease.
C. Side and adverse effects

1. Sodium and water retention, edema, hypertension
2. Hypokalemia
3. Hypocalcemia
4. Osteoporosis, compression fractures
5. Weight gain
6. Heart failure

D. Interventions

1. Monitor vital signs.
2. Monitor intake and output, weight, and for edema.
3. Monitor electrolyte and calcium levels.
4. Instruct the client to take medication with food or milk.
5. Instruct the client to consume a high-potassium diet.
6. Instruct the client to report signs of illness.
7. Instruct the client to notify the PHCP if low blood pressure, weakness, cramping, palpitations, or changes in mental status occur.
8. Instruct the client to wear a MedicAlert bracelet.

Instruct the client taking a corticosteroid not to stop the medication abruptly, because this could result in adrenal insufficiency.

VII. Corticosteroids: Glucocorticoids (Box 47-5)

A. Description

1. Glucocorticoids affect glucose, protein, and bone metabolism; alter the normal immune response and suppress inflammation; and produce anti-inflammatory, antiallergic, and antistress effects.
2. Glucocorticoids may be used as a replacement in adrenocortical insufficiency.
3. Glucocorticoids are used for their anti-inflammatory and immunosuppressant effects both short-term and long-term in the treatment of several nonendocrine disorders.

B. Side and adverse effects

1. Adrenal insufficiency
2. Hyperglycemia
3. Hypokalemia
4. Hypocalcemia, osteoporosis
5. Sodium and fluid retention
6. Weight gain and edema
7. Mood swings
8. Moon face, buffalo hump, truncal obesity
9. Increased susceptibility to infection and masking of the signs and symptoms of infection
10. Cataracts
11. Hirsutism, acne, fragile skin, bruising
12. Growth retardation in children
13. GI irritation, peptic ulcer, pancreatitis
14. Seizures
15. Psychosis (usually occurs with hydrocortisone and dexamethasone in clients receiving very high doses long-term and is most likely due to their effects on blood glucose)

C. Contraindications and cautions

1. Contraindicated in clients with hypersensitivity, psychosis, and fungal infections
2. Should be used with caution in clients with diabetes mellitus
3. Should be used with extreme caution in clients with infections because they mask the signs and symptoms of an infection
4. They can increase the potency of medications taken concurrently, such as aspirin and nonsteroidal antiinflammatory drugs, thus increasing the risk of GI bleeding and ulceration.
5. Use of potassium-losing diuretics increases potassium loss, resulting in hypokalemia.
6. Dexamethasone decreases the effects of orally administered anticoagulants and antidiabetic agents.
7. Barbiturates, phenytoin, and rifampin decrease the effect of prednisone.

D. Interventions

1. Monitor vital signs.
2. Monitor serum electrolyte and blood glucose levels.
4. Monitor intake and output, weight, and for edema.
5. Monitor for hypertension.
6. Assess medical history for glaucoma, cataracts, peptic ulcer, mental health disorders, or diabetes mellitus.
7. Monitor the older client for signs and symptoms of increased osteoporosis.
8. Assess for changes in muscle strength.
9. Prepare a schedule as needed for the client, with information on short-term tapered doses.
10. Instruct the client that it is best to take medication in the early morning with food or milk.
11. Advise the client to eat foods high in potassium.
12. Instruct the client to avoid individuals with infections.
13. Advise the client to inform all PHCPs of the medication regimen.
14. Instruct the client to report signs and symptoms of Cushing’s syndrome, including a moon face, puffy eyelids, edema in the feet, increased bruising, dizziness, bleeding, and menstrual irregularities, which often results from the large doses of long-term glucocorticoids that may be used to treat nonendocrine conditions.
15. Note that the client may need additional doses during periods of stress, such as surgery.
16. Instruct the client not to stop the medication abruptly, because abrupt withdrawal can result in severe adrenal insufficiency.
17. Advise the client to consult with the PHCP before receiving vaccinations; live virus vaccines should not be administered to the client taking glucocorticoids.
18. Advise the client to wear a MedicAlert bracelet.

VIII. Androgens (Box 47-6)

A. Description

1. Used to replace deficient hormones or to treat hormone-sensitive disorders
2. Can cause bleeding if the client is taking oral anticoagulants (increase the effect of anticoagulants)
3. Can cause decreased serum glucose concentration, thereby reducing insulin requirements in the client with diabetes mellitus
4. Hepatotoxic medications are avoided with the use of androgens because of the risk of additive damage to the liver.
5. Androgens usually are avoided in men with known prostate or breast carcinoma, because androgens often stimulate growth of these tumors.

B. Side and adverse effects

1. Masculine secondary sexual characteristics (body hair growth, lowered voice, muscle growth)
2. Bladder irritation and urinary tract infections
3. Breast tenderness
4. Gynecomastia
5. Priapism
6. Menstrual irregularities
7. Virilism
8. Sodium and water retention with edema
9. Nausea, vomiting, or diarrhea
10. Acne
11. Changes in libido
12. Hepatotoxicity, jaundice
13. Hypercalcemia

C. Interventions
1. Monitor vital signs.
2. Monitor for edema, weight gain, and skin changes.
3. Assess mental status and neurological function.
4. Assess for signs of liver dysfunction, including right upper quadrant abdominal pain, malaise, fever, jaundice, and pruritus.
5. Assess for the development of secondary sexual characteristics.
6. Instruct the client to take medication with meals or a snack.
7. Instruct the client to notify the PHCP if priapism develops.
8. Instruct the client to notify the PHCP if fluid retention occurs.
9. Instruct women to use a nonhormonal contraceptive while on therapy.
10. For women, monitor for menstrual irregularities and decreased breast size.

IX. Estrogens and Progestins
A. Description
1. Estrogens are steroids that stimulate female reproductive tissue.
2. Progestins are steroids that specifically stimulate the uterine lining.
3. Estrogen and progestin preparations may be used to stimulate the endogenous hormones to restore hormonal balance or to treat hormone-sensitive tumors (suppress tumor growth) or for contraception (Boxes 47-7 and 47-8).

B. Contraindications and cautions
1. Estrogens
   a. Estrogens are contraindicated in clients with breast cancer, endometrial hyperplasia, endometrial cancer, history of thromboembolism, known or suspected pregnancy, or lactation.
   b. Use estrogens with caution in clients
with hypertension, gallbladder disease, or liver or kidney dysfunction.
c. Estrogens increase the risk of toxicity when used with hepatotoxic medications.
d. Barbiturates, phenytoin, and rifampin decrease the effectiveness of estrogen.

2. Progestins are contraindicated in clients with thromboembolic disorders and should be avoided in clients with breast tumors or hepatic disease.

C. Side and adverse effects
1. Breast tenderness, menstrual changes
2. Nausea, vomiting, and diarrhea
3. Malaise, depression, excessive irritability
4. Weight gain
5. Edema and fluid retention
6. Atherosclerosis
7. Hypertension, stroke, myocardial infarction
8. Thromboembolism (estrogen)
9. Migraine headaches and vomiting (estrogen)

D. Interventions
1. Monitor vital signs.
3. Assess for edema and weight gain.
4. Advise the client not to smoke.
5. Advise the client to undergo routine breast and pelvic examinations.

X. Medications for Diabetes Mellitus
A. Insulin and oral antidiabetic medications
1. Description
   a. Insulin increases glucose transport into cells and promotes conversion of glucose to glycogen, decreasing serum glucose levels.
   b. Oral antidiabetic agents act in a number of ways: stimulate the pancreas to produce more insulin, increase the sensitivity of peripheral receptors to insulin, decrease hepatic glucose output, delay intestinal absorption of
glucose, enhance the activity of incretins, and promote glucose loss through the kidney.

2. Contraindications and concerns
   a. Oral antidiabetic agents, except the sodium-glucose cotransporter 2 (SGLT-2) inhibitors, are contraindicated in type 1 diabetes mellitus.
   b. β-Adrenergic blocking agents may mask signs and symptoms of hypoglycemia associated with hypoglycemia-producing medications.
   c. Anticoagulants, chloramphenicol, salicylates, propranolol, monoamine oxidase inhibitors, pentamidine, and sulfonamides may cause hypoglycemia.
   d. Corticosteroids, sympathomimetics, thiazide diuretics, phenytoin, thyroid preparations, oral contraceptives, and estrogen compounds may cause hyperglycemia.
   e. Side and adverse effects of the sulfonylureas include GI symptoms and dermatological reactions; hypoglycemia can occur when an excessive dose is administered or when meals are omitted or delayed, food intake is decreased, or activity is increased.

   *Sulfonylureas can cause a disulfiram type of reaction when alcohol is ingested.*

B. Medications for type 2 diabetes mellitus (Table 47-1)

1. Interventions
   a. Assess the client’s knowledge of diabetes mellitus and the use of oral antidiabetic agents.
b. Obtain a medication history regarding the medications that the client is taking currently.

c. Assess vital signs and blood glucose levels.

d. Instruct the client to recognize the signs and symptoms of hypoglycemia and hyperglycemia.

e. Instruct the client to avoid over-the-counter medications unless prescribed by the PHCP.

f. Instruct the client not to ingest alcohol with sulfonylureas.

g. Inform the client that insulin may be needed during times of increased stress, surgery, or infection.

h. Instruct the client on the necessity for compliance with prescribed medication.

i. Instruct the client about how to take each specific medication, such as with the first bite of the meal for meglitinides and α-glucosidase inhibitors.

j. Advise the client to wear a MedicAlert bracelet.

Metformin needs to be withheld temporarily before and for 48 hours after having any radiological study that involves the administration of intravenous contrast dye because of the risk of contrast-induced nephropathy and lactic acidosis. The PHCP needs to be consulted for specific prescriptions.

C. Insulin

1. Insulin acts primarily in the liver, muscle, and adipose tissue by attaching to receptors on cellular membranes and facilitating the passage of glucose, potassium, and magnesium.

2. Insulin is prescribed for clients with type 1 diabetes mellitus and for clients with type 2 diabetes mellitus whose blood glucose levels are not adequately
controlled with oral antidiabetic agents.

3. The onset, peak, and duration of action depend on the insulin type (Tables 47-2 and 47-3).

4. Storing of insulin (Box 47-9)

5. Insulin injection sites

   a. The main areas for injections are the abdomen, arms (posterior surface), thighs (anterior surface), and hips (Fig. 47-1).

   b. Insulin injected into the abdomen may absorb more evenly and rapidly than at other sites.

   c. Systematic rotation within 1 anatomical area is recommended to prevent lipodystrophy and to promote more even absorption; clients should be instructed not to use the same site more than once in a 2- to 3-week period.

   d. Injections should be 1 to 1.5 inches (2.5 to 3.8 cm) apart within the anatomical area.

   e. Heat, massage, and exercise of the injected area can increase absorption rates and may result in hypoglycemia.

   f. Injection into scar tissue may delay absorption of insulin.

6. Administering insulin (also see Chapter 46)

   ? Insulin glargine cannot be mixed with any other types of insulin.

   a. To prevent dosage errors, be certain that there is a match between the insulin concentration noted on the vial and the calibration of units on the insulin syringe; the usual concentration of insulin is U-100 (100 units/mL).

   b. The Humulin R brand of regular insulin is the only insulin that is formulated in a U-500 strength. U-500 strength
insulin is reserved for clients with severe insulin resistance who require large doses of insulin. A special syringe calibrated for use with U-500 insulin is required.
c. Prefilled syringes (pens) are commonly used; a new needle needs to be attached before each injection.
d. Most insulin syringes have a 27- to 29-gauge needle that is about 0.5-inch long (1.3 cm).
e. NPH insulin is an insulin suspension; the appearance is cloudy. All other insulin types are solutions; the appearance of all other insulin products is clear.
f. Before use, NPH insulins must be rotated, or rolled, between the palms to ensure that the insulin suspension is mixed well; otherwise, an inaccurate dose will be drawn; vigorously shaking the bottle will cause bubbles to form. It is not necessary to rotate or roll clear insulins before using.
g. Inject air into the insulin bottle (a vacuum makes it difficult to draw up the insulin).
h. When mixing insulins, draw up the shortest-acting insulin first.
i. Short-duration (i.e., regular, lispro, aspart, and glulisine) insulin may be mixed with NPH.
j. Administer a mixed dose of insulin within 5 to 15 minutes of preparation; after this time, the short-acting insulin binds with the NPH insulin and its action is reduced.
k. Aspiration after insertion of the needle generally is not recommended with self-injection of insulin.
l. Administer insulin at a 45- to 90-degree angle in clients with normal subcutaneous mass and at a 45- to 60-degree angle in thin persons or those with a decreased amount of
D. Glucagon-like peptide (GLP-1) receptor agonists

1. Noninsulin injectable agents that are analogs of human GLP-1 and cause the same effects as the GLP-1 incretin hormone in the body, which are to stimulate the glucose level–dependent release of insulin, to suppress the postprandial release of glucagon, to slow gastric emptying, and to suppress appetite

2. Used for clients with type 2 diabetes mellitus (not recommended for clients taking insulin, nor should clients be taken off insulin and given a GLP-1 receptor agonist)

3. GLP-1 receptor agonists restore the first-phase insulin response (first 10 minutes after food ingestion), lower the production of glucagon after meals, slow gastric emptying (which limits the rise in blood glucose level after a meal), reduce fasting and postprandial blood glucose levels, and reduce caloric intake, resulting in weight loss

4. Packaged in premeasured doses (pens) that require refrigeration (cannot be frozen)

5. Administered as a subcutaneous injection in the thigh, abdomen, or upper arm. Exenatide is administered twice daily within 60 minutes before morning and evening meals (not taken after meals); if a dose is missed, the treatment regimen is resumed as prescribed with the next scheduled dose. Liraglutide is administered subcutaneously once daily without regard to meals. Albiglutide is injected subcutaneously once weekly.

6. Can cause mild to moderate nausea that abates with use.

7. Because delayed gastric emptying slows the absorption of other medications, other prescribed oral medications should be given an hour before injection of these medications.

E. Amylin Mimetic: Pramlintide

1. Synthetic form of amylin, a naturally occurring hormone secreted by the pancreas

2. Used for clients with types 1 and 2 diabetes mellitus who use insulin; administered...
subcutaneously before meals to lower blood glucose level after meals, leading to less fluctuation during the day and better long-term glucose control.

3. Associated with an increased risk of insulin-induced severe hypoglycemia, particularly in clients with type 1 diabetes mellitus.

4. GI effects, including nausea, can occur.

5. Unopened vials are refrigerated; opened vials can be refrigerated or kept at room temperature for up to 28 days.

6. Reduces postprandial hyperglycemia by delaying gastric emptying and suppressing postprandial glucagon release.

7. Because pramlintide delays gastric emptying, other prescribed oral medications should be given 1 hour before or 2 hours after an injection of pramlintide.

F. Glucagon

1. Hormone secreted by the alpha cells of the islets of Langerhans in the pancreas.

2. Increases blood glucose level by stimulating glycogenolysis in the liver.

3. Can be administered subcutaneously, intramuscularly, or intravenously.

4. Used to treat insulin-induced hypoglycemia when the client is semiconscious or unconscious and is unable to ingest liquids.

5. The blood glucose level begins to increase within 5 to 20 minutes after administration.

6. Instruct the family in the procedure for administration.

7. See Chapter 46 for additional information regarding insulin and interventions for hypoglycemia.

**Box 47-1**

**Growth Hormones and Related Medications**

**Growth Hormones**

- Somatropin
- Norditropin
- Mecasermin
Growth Hormone Receptor Antagonists

▪ Octreotide acetate
▪ Lanreotide
▪ Pegvisomant

Box 47-2

Thyroid Hormones

▪ Levothyroxine sodium
▪ Liothyronine sodium
▪ Liotrix
▪ Thyroid, desiccated

Box 47-3

Antithyroid Medications

▪ Methimazole
▪ Propylthiouracil
▪ Potassium iodide and strong iodine solution

Box 47-4

Medications to Treat Calcium Disorders

Oral Calcium Supplements

▪ Calcium acetate
▪ Calcium carbonate
▪ Calcium citrate
▪ Calcium gluconate
▪ Calcium gluconate
▪ Tribasic calcium phosphate

Vitamin D Supplements

▪ Cholecalciferol (vitamin D₃)
▪ Ergocalciferol (vitamin D₂)
Bisphosphonates and Calcium Regulators

- Alendronate sodium
- Calcitonin salmon
- Etidronate disodium
- Ibandronate
- Pamidronate disodium
- Risedronate sodium
- Zoledronic acid

Medications to Treat Hypercalcemia

- Cinacalcet hydrochloride
- Doxercalciferol
- Calcitonin
- Paricalcitol

Box 47-5
Corticosteroids: Glucocorticoids

- Betamethasone
- Cortisone acetate
- Dexamethasone
- Hydrocortisone
- Methylprednisolone
- Prednisolone
- Prednisone
- Triamcinolone

Box 47-6
Androgens

- Methyltestosterone

Testosterone Preparations

- Testosterone, pellets
- Testosterone, transdermal
• Testosterone cypionate
• Testosterone enanthate
• Testosterone propionate
• Testosterone undecanoate
• Testosterone, buccal patch
• Testosterone, topical gel
• Testosterone, nasal gel

**Box 47-7**

**Estrogens**

• Esterified estrogens
• Estradiol
• Estrogens, conjugated
• Ethinyl estradiol

**Box 47-8**

**Progestins**

• Estradiol/drospirenone
• Estradiol/norgestimate
• Estradiol/levonorgestrel
• Estradiol/norethindrone
• Estradiol/etonogestrel
• Medroxyprogesterone acetate
• Medroxyprogesterone and conjugated estrogens
• Megestrol acetate
• Norethindrone acetate
• Levonorgestrel
• Progesterone

Storing Insulin

- Avoid exposing insulin to extremes in temperature.
- Insulin should not be frozen or kept in direct sunlight or a hot car.
- Before injection, insulin should be at room temperature.
- If a vial of insulin will be used up in 1 month, it may be kept at room temperature; otherwise, the vial should be refrigerated.

![Common insulin injection sites.](image)

**FIG. 47-1** Common insulin injection sites.

**Practice Questions**

512. The nurse is teaching a client with diabetes mellitus how to mix regular insulin and NPH insulin in the same syringe. Which action, if performed by the client, indicates the need for further teaching?
   1. Withdraws the NPH insulin first
   2. Withdraws the regular insulin first
   3. Injects air into NPH insulin vial first
   4. Injects an amount of air equal to the desired dose of insulin into each vial

513. The home care nurse visits a client recently diagnosed with diabetes mellitus who is taking Humulin NPH insulin daily. The client asks the nurse how to
store the unopened vials of insulin. The nurse should tell the client to take which action?

1. Freeze the insulin.
2. Refrigerate the insulin.
3. Store the insulin in a dark, dry place.
4. Keep the insulin at room temperature.

514. Glimepiride is prescribed for a client with diabetes mellitus. The nurse instructs the client that which food items are most acceptable to consume while taking this medication? Select all that apply.

1. Alcohol
2. Red meats
3. Whole-grain cereals
4. Low-calorie desserts
5. Carbonated beverages

515. The nurse is providing discharge teaching for a client newly diagnosed with type 2 diabetes mellitus who has been prescribed metformin. Which client statement indicates the need for further teaching?

1. “It is okay if I skip meals once in a while.”
2. “I need to let my doctor know if I get unusually tired.”
3. “I need to constantly watch for signs of low blood sugar.”
4. “I will be sure to not drink alcohol excessively while on this medication.”

516. The primary health care provider (PHCP) prescribes exenatide for a client with type 1 diabetes mellitus who takes insulin. The nurse should plan to take which most appropriate intervention?

1. Withhold the medication and call the PHCP, questioning the prescription for the client.
2. Teach the client about the signs and symptoms of hypoglycemia and hyperglycemia.
3. Monitor the client for gastrointestinal side effects after administering the medication.
4. Withdraw the insulin from the prefilled pen into an insulin syringe to prepare for administration.

517. A client with diabetes mellitus is taking Humulin NPH insulin and regular insulin every morning. The nurse should provide which instructions to the client? Select all that apply.

1. Hypoglycemia may be experienced before dinnertime.
2. The insulin dose should be decreased if illness occurs.
3. The insulin should be administered at room temperature.
4. The insulin vial needs to be shaken vigorously to break up the precipitates.
5. The NPH insulin should be drawn into the syringe first, then the regular insulin.

518. The home health care nurse is visiting a client who was recently diagnosed with type 2 diabetes mellitus. The client is prescribed repaglinide and
metformin. The nurse should provide which instructions to the client? Select all that apply.

1. Diarrhea may occur secondary to the metformin.
2. The repaglinide is not taken if a meal is skipped.
3. The repaglinide is taken 30 minutes before eating.
4. A simple sugar food item is carried and used to treat mild hypoglycemia episodes.
5. Muscle pain is an expected effect of metformin and may be treated with acetaminophen.
6. Metformin increases hepatic glucose production to prevent hypoglycemia associated with repaglinide.

519. The nurse is teaching the client about his prescribed prednisone. Which statement, if made by the client, indicates that further teaching is necessary?

1. “I can take aspirin or my antihistamine if I need it.”
2. “I need to take the medication every day at the same time.”
3. “I need to avoid coffee, tea, cola, and chocolate in my diet.”
4. “If I gain 5 pounds or more a week, I will call my doctor.”

520. A client with hyperthyroidism has been given methimazole. Which nursing considerations are associated with this medication? Select all that apply.

1. Administer methimazole with food.
2. Place the client on a low-calorie, low-protein diet.
3. Assess the client for unexplained bruising or bleeding.
4. Instruct the client to report side and adverse effects such as sore throat, fever, or headaches.
5. Use special radioactive precautions when handling the client’s urine for the first 24 hours following initial administration.

521. The nurse is monitoring a client receiving levothyroxine sodium for hypothyroidism. Which findings indicate the presence of a side effect associated with this medication? Select all that apply.

1. Insomnia
2. Weight loss
3. Bradycardia
4. Constipation
5. Mild heat intolerance

522. The nurse provides instructions to a client who is taking levothyroxine. The nurse should tell the client to take the medication in which way?

1. With food
2. At lunchtime
3. On an empty stomach
4. At bedtime with a snack

523. The nurse should tell the client who is taking levothyroxine to notify the primary health care provider (PHCP) if which problem occurs?
   1. Fatigue
   2. Tremors
   3. Cold intolerance
   4. Excessively dry skin

524. The nurse is providing instructions to the client newly diagnosed with diabetes mellitus who has been prescribed pramlintide. Which instruction should the nurse include in the discharge teaching?
   1. “Inject the pramlintide at the same time you take your other medications.”
   2. “Take your prescribed pills 1 hour before or 2 hours after the injection.”
   3. “Be sure to take the pramlintide with food so you don’t upset your stomach.”
   4. “Make sure you take your pramlintide immediately after you eat so you don’t experience a low blood sugar.”

525. The nurse teaches the client who is newly diagnosed with diabetes insipidus about the prescribed intranasal desmopressin. Which statements by the client indicate understanding? **Select all that apply.**
   1. “This medication will turn my urine orange.”
   2. “I should decrease my oral fluids when I start this medication.”
   3. “The amount of urine I make should increase if this medicine is working.”
   4. “I need to follow a low-fat diet to avoid pancreatitis when taking this medicine.”
   5. “I should report headache and drowsiness to my doctor since these symptoms could be related to my desmopressin.”

526. A daily dose of prednisone is prescribed for a client. The nurse provides instructions to the client regarding administration of the medication and should instruct the client that which time is **best** to take this medication?
   1. At noon
   2. At bedtime
   3. Early morning
   4. Any time, at the same time, each day

527. The client with hyperparathyroidism is taking alendronate. Which statements by the client indicate understanding of the proper way to take this medication? **Select all that apply.**
   1. “I should take this medication with food.”
   2. “I should take this medication at bedtime.”
   3. “I should sit up for at least 30 minutes after taking this
medication.”

4. “I should take this medication first thing in the morning on an empty stomach.”

5. “I can pick a time to take this medication that best fits my lifestyle as long as I take it at the same time each day.”

528. A client with diabetes mellitus visits a health care clinic. The client’s diabetes mellitus previously had been well controlled with glyburide daily, but recently the fasting blood glucose level has been 180 to 200 mg/dL (10 to 11.1 mmol/L). Which medication, if added to the client’s regimen, may have contributed to the hyperglycemia?

1. Atenolol
2. Prednisone
3. Phenelzine
4. Allopurinol

Answers

512. Answer: 1

Rationale: When preparing a mixture of short-acting insulin, such as regular insulin, with another insulin preparation, the short-acting insulin is drawn into the syringe first. This sequence will avoid contaminating the vial of short-acting insulin with insulin of another type. Options 2, 3, and 4 identify correct actions for preparing NPH and short-acting insulin.

Test-Taking Strategy: Note the strategic words, need for further teaching. These words indicate a negative event query and ask you to select an option that is an incorrect action. Remember RN—draw up the Regular (short-acting) insulin before the NPH insulin.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Pharmacology: Endocrine Medications: Insulin
Health Problem: Adult Health: Endocrine: Diabetes mellitus
Priority Concepts: Client Education; Glucose Regulation

513. Answer: 2

Rationale: Insulin in unopened vials should be stored under refrigeration until needed. Vials should not be frozen. When stored unopened under refrigeration, insulin can be used up to the expiration date on the vial. Options 1, 3, and 4 are incorrect.

Test-Taking Strategy: Note the subject, how to store unopened vials of insulin. Options 3 and 4 are comparable or alike regarding where to store the insulin and should be eliminated. Remembering that insulin should not be frozen will assist in
eliminating option 1.

Rationale: When alcohol is combined with glimepiride, a disulfiram-like reaction may occur. This syndrome includes flushing, palpitations, and nausea. Alcohol can also potentiate the hypoglycemic effects of the medication. Clients need to be instructed to avoid alcohol consumption while taking this medication. Low-calorie desserts should also be avoided. Even though the calorie content may be low, carbohydrate content is most likely high and can affect the blood glucose. The items in options 2, 3, and 5 are acceptable to consume.

Test-Taking Strategy: Note the strategic word, most. Remembering that alcohol can affect the action of many medications will assist in eliminating option 1. Next, recalling that carbohydrates need to be controlled in a diabetic diet will assist in eliminating option 4.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Pharmacology: Endocrine Medications: Insulin
Health Problem: Adult Health: Endocrine: Diabetes mellitus
Priority Concepts: Client Education; Safety

515. Answer: 3

Rationale: Metformin is classified as a biguanide and is the most commonly used medication for type 2 diabetes mellitus initially. It is also often used as a preventive medication for those at high risk for developing diabetes mellitus. When used alone, metformin lowers the blood glucose after meal intake as well as fasting blood glucose levels. Metformin does not stimulate insulin release and therefore poses little risk for hypoglycemia. For this reason, metformin is well suited for clients who skip meals. Unusual somnolence as well as hyperventilation, myalgia, and malaise are early signs of lactic acidosis, a toxic effect associated with metformin. If any of these signs or symptoms occur, the client should inform the primary health care provider immediately. While it is best to avoid consumption of alcohol, it is not always realistic or feasible for clients to quit drinking altogether; for this reason, clients should be informed that excessive alcohol intake can cause an adverse reaction with metformin.

Test-Taking Strategy: Note the strategic words, need for further teaching. These words indicate a negative event query and the need to select the incorrect client
statement as the answer. Recalling the adverse effects and drug interactions associated with this medication will assist you in eliminating options 2 and 4. Next, recalling the mechanism of action of this medication will help you determine that this medication is suited for clients who skip meals, thereby leading you to the correct option.

Rationale: Exenatide is an incretin mimetic used for type 2 diabetes mellitus only. It is not recommended for clients taking insulin. Hence the nurse should withhold the medication and question the PHCP regarding this prescription. Although options 2 and 3 are correct statements about the medication, in this situation the medication should not be administered. The medication is packaged in prefilled pens ready for injection without the need for drawing it up into another syringe.

Test-Taking Strategy: Note the strategic words, most appropriate. Focus on the name of the medication, recalling that it is used for the treatment of type 2 diabetes mellitus. Eliminate option 4 because the medication is packaged in prefilled pens ready for injection. From the remaining options, focus on the data in the question. Although options 2 and 3 are appropriate when administering this medication, this client should not receive this medication.

Rationale: Humulin NPH is an intermediate-acting insulin. The onset of action is 60 to 120 minutes, it peaks in 6 to 14 hours, and its duration of action is 16 to 24 hours. Regular insulin is a short-acting insulin. Depending on the type, the onset of action is 30 to 60 minutes, it peaks in 1 to 5 hours, and its duration is 6 to 10 hours. Hypoglycemic reactions most likely occur during peak time. Insulin should be at room temperature when administered. Clients may need their insulin dosages increased during times of illness. Insulin vials should never be shaken vigorously. Regular insulin is always drawn up before NPH.

Test-Taking Strategy: Focus on the subject, client instructions regarding insulin. Eliminate option 4 because of the word vigorously. Use knowledge regarding the
characteristics of insulin; procedures for administration; and the onset, peak, and duration of action for insulin and insulin administration to select from the remaining options. Remember that NPH insulin peaks in 6 to 14 hours and regular insulin peaks in 1 to 5 hours.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Pharmacology: Endocrine Medications: Insulin  
**Health Problem:** Adult Health: Endocrine: Diabetes mellitus  
**Priority Concepts:** Client Education; Glucose Regulation  

518. Answer: 1, 2, 3, 4

**Rationale:** Repaglinide, a rapid-acting oral hypoglycemic agent that stimulates pancreatic insulin secretion, should be taken before meals (approximately 30 minutes before meals) and should be withheld if the client does not eat. Hypoglycemia is a side effect of repaglinide and the client should always be prepared by carrying a simple sugar at all times. Metformin is an oral hypoglycemic given in combination with repaglinide and works by decreasing hepatic glucose production. A common side effect of metformin is diarrhea. Muscle pain may occur as an adverse effect from metformin, but it might signify a more serious condition that warrants primary health care provider notification, not the use of acetaminophen.

**Test-Taking Strategy:** Focus on the subject, oral medications to treat diabetes mellitus. Thinking about the pathophysiology of diabetes mellitus and recalling the actions and effects of these medications are needed to answer correctly.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Pharmacology: Endocrine Medications: Oral Hypoglycemic  
**Health Problem:** Adult Health: Endocrine: Diabetes mellitus  
**Priority Concepts:** Client Education; Glucose Regulation  

519. Answer: 1

**Rationale:** Aspirin and other over-the-counter medications should not be taken unless the client consults with the PHCP. The client needs to take the medication at the same time every day and should be instructed not to stop the medication. A slight weight gain as a result of an improved appetite is expected; however, after the dosage is stabilized, a weight gain of 5 pounds (2.25 kg) or more weekly should be reported to the PHCP. Caffeine-containing foods and fluids need to be avoided because they may contribute to steroid-ulcer development.

**Test-Taking Strategy:** Note the strategic words, further teaching is necessary. These words indicate a negative event query and ask you to select an option that is an incorrect statement. Remember that a client taking prednisone should not take other
medications, especially over-the-counter medications, without first consulting with her or his PHCP.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Pharmacology: Endocrine Medications: Corticosteroids  
**Health Problem:** N/A  
**Priority Concepts:** Client Education; Safety  
**Reference:** Skidmore-Roth (2017), pp. 966-967.

520. **Answer:** 1, 3, 4

**Rationale:** Common side effects of methimazole include nausea, vomiting, and diarrhea. To address these side effects, this medication should be taken with food. Because of the increase in metabolism that occurs in hyperthyroidism, the client should consume a high-calorie diet. Antithyroid medications can cause agranulocytosis with leukopenia and thrombocytopenia. Sore throat, fever, headache, or bleeding may indicate agranulocytosis and the primary health care provider should be notified immediately. Methimazole is not radioactive and should not be stopped abruptly, due to the risk of thyroid storm.

**Test-Taking Strategy:** Focus on the subject, nursing considerations for administering methimazole. Focus on the client’s diagnosis. Think about the pathophysiology associated with the diagnosis and the medication and the actions and effects of antithyroid medications to assist in answering correctly.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Pharmacology: Endocrine Medications: Antithyroid Medications  
**Health Problem:** Adult Health: Endocrine: Thyroid Disorders  
**Priority Concepts:** Clinical Judgment; Safety  
**Reference:** Skidmore-Roth (2017), pp. 761-762.

521. **Answer:** 1, 2, 5

**Rationale:** Insomnia, weight loss, and mild heat intolerance are side effects of levothyroxine sodium. Bradycardia and constipation are not side effects associated with this medication, and rather are associated with hypothyroidism, which is the disorder that this medication is prescribed to treat.

**Test-Taking Strategy:** Focus on the subject, side effects of levothyroxine. Thinking about the pathophysiology of hypothyroidism and the action of the medication will assist you in determining that insomnia, weight loss, and mild heat intolerance are side effects of thyroid hormones.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Endocrine Medications: Thyroid Hormones  
**Health Problem:** Adult Health: Endocrine: Thyroid Disorders
Priority Concepts: Clinical Judgment; Thermoregulation

522. Answer: 3

Rationale: Oral doses of levothyroxine should be taken on an empty stomach to enhance absorption. Dosing should be done in the morning before breakfast.
Test-Taking Strategy: Note that options 1, 2, and 4 are comparable or alike in that these options address administering the medication with food.
Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Pharmacology: Endocrine Medications: Thyroid Hormones
Health Problem: Adult Health: Endocrine: Thyroid Disorders
Priority Concepts: Client Education; Thermoregulation

523. Answer: 2

Rationale: Excessive doses of levothyroxine can produce signs and symptoms of hyperthyroidism. These include tachycardia, chest pain, tremors, nervousness, insomnia, hyperthermia, extreme heat intolerance, and sweating. The client should be instructed to notify the PHCP if these occur. Options 1, 3, and 4 are signs of hypothyroidism.
Test-Taking Strategy: Focus on the subject, the need to notify the PHCP. Recall the symptoms associated with hypothyroidism, the purpose of administering levothyroxine, and the effects of the medication. Options 1, 3, and 4 are symptoms related to hypothyroidism.
Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Pharmacology: Endocrine Medications: Thyroid Hormones
Health Problem: Adult Health: Endocrine: Thyroid Disorders
Priority Concepts: Client Education; Safety

524. Answer: 2

Rationale: Pramlintide is used for clients with types 1 and 2 diabetes mellitus who use insulin. It is administered subcutaneously before meals to lower blood glucose level after meals, leading to less fluctuation during the day and better long-term glucose control. Because pramlintide delays gastric emptying, any prescribed oral medications should be taken 1 hour before or 2 hours after an injection of pramlintide; therefore, instructing the client to take his or her pills 1 hour before or 2 hours after the injection is correct. Pramlintide should not be taken at the same time as other medications. Pramlintide is given immediately before the meal in order to control postprandial rise in blood glucose, not necessarily to prevent stomach upset.
It is incorrect to instruct the client to take the medication after eating, as it will not achieve its full therapeutic effect.

**Test-Taking Strategy:** Focus on the **subject**, client instructions regarding pramlintide as it pertains to administration. Use knowledge regarding the action of the medication and treatment measures for diabetes mellitus to answer the question. Remember that this medication is used in conjunction with insulin to prevent postprandial rise in blood glucose, and that hypoglycemia is a potential adverse effect. Also remember that this medication causes delayed gastric emptying and should not be taken with other medications.

**Level of Cognitive Ability:** Applying
**Client Needs:** Physiological Integrity
**Integrated Process:** Teaching and Learning
**Content Area:** Pharmacology: Endocrine Medications: Oral Hypoglycemics
**Health Problem:** Adult Health: Endocrine: Diabetes mellitus
**Priority Concepts:** Client Education; Safety

525. **Answer:** 2, 5

**Rationale:** In diabetes insipidus, there is a deficiency in antidiuretic hormone (ADH), resulting in large urinary losses. Desmopressin is an antidiuretic hormone that enhances reabsorption of water in the kidney. Clients with diabetes insipidus drink high volumes of fluid (polydipsia) as a compensatory mechanism to counteract urinary losses and maintain fluid balance. Once desmopressin is started, oral fluids should be decreased to prevent water intoxication. Therefore, clients with diabetes insipidus should decrease their oral fluid intake when they start desmopressin. Headache and drowsiness are signs of water intoxication in the client taking desmopressin and should be reported to the primary health care provider. Desmopressin does not turn urine orange. The amount of urine should decrease, not increase, when desmopressin is started. Desmopressin does not cause pancreatitis.

**Test-Taking Strategy:** Focus on the **subject**, understanding of desmopressin. Recall that in diabetes insipidus there is a deficiency of ADH and that desmopressin is an antidiuretic hormone. Recalling the pathophysiology of this disorder will assist you in answering correctly.

**Level of Cognitive Ability:** Evaluating
**Client Needs:** Physiological Integrity
**Integrated Process:** Nursing Process—Evaluation
**Content Area:** Pharmacology: Endocrine Medications: Antidiuretics
**Health Problem:** Adult Health: Endocrine: Pituitary disorders
**Priority Concepts:** Client Education; Fluids and Electrolytes
**Reference:** Skidmore-Roth (2017), pp. 343-344.

526. **Answer:** 3

**Rationale:** Corticosteroids (glucocorticoids) should be administered before 9 a.m. Administration at this time helps minimize adrenal insufficiency and mimics the burst of glucocorticoids released naturally by the adrenal glands each morning.
Options 1, 2, and 4 are incorrect.

**Test-Taking Strategy:** Note the **strategic word**, best. Note the suffix -sone and recall that medication names that end with these letters are corticosteroids. Remember that a daily dose of a corticosteroid should be administered in the morning.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Endocrine Medications: Corticosteroids

**Health Problem:** N/A

**Priority Concepts:** Client Education; Hormonal Regulation

527. **Answer:** 3, 4

**Rationale:** Alendronate is a bisphosphonate used in hyperparathyroidism to inhibit bone loss and normalize serum calcium levels. Esophagitis is an adverse effect of primary concern in clients taking alendronate. For this reason the client is instructed to take alendronate first thing in the morning with a full glass of water on an empty stomach, not to eat or drink anything else for at least 30 minutes after taking the medication, and to remain sitting upright for at least 30 minutes after taking it.

**Test-Taking Strategy:** Focus on the **subject**, the correct method to take alendronate. Recall that the primary concern with alendronate is esophagitis. Eliminate options 1 and 2, since taking with food and taking at bedtime will each place the client at increased risk of reflux. Eliminate option 5 because alendronate should be taken first thing in the morning on an empty stomach.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Evaluation

**Content Area:** Pharmacology: Endocrine Medications: Bisphosphonates and Calcium Regulators

**Health Problem:** Adult Health: Endocrine: Parathyroid Disorders

**Priority Concepts:** Client Education; Safety

**Reference:** Lewis et al. (2017), p. 1513.

528. **Answer:** 2

**Rationale:** Prednisone may decrease the effect of oral hypoglycemics, insulin, diuretics, and potassium supplements. Option 1, a beta blocker, and option 3, a monoamine oxidase inhibitor, have their own intrinsic hypoglycemic activity. Option 4 decreases urinary excretion of sulfonylurea agents, causing increased levels of the oral agents, which can lead to hypoglycemia.

**Test-Taking Strategy:** Focus on the **subject**, an increase in the blood glucose level. Recalling that prednisone is a corticosteroid and that corticosteroids decrease the effects of hypoglycemics will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Pharmacology: Endocrine Medications: Corticosteroids
Health Problem: Adult Health: Endocrine: Diabetes Mellitus
Priority Concepts: Clinical Judgment; Glucose Regulation
UNIT X
Gastrointestinal Problems of the Adult Client
Introduction

Pyramid to Success

Pyramid Points focus on diagnostic tests and nursing care related to the various gastric or intestinal tubes, gastric surgery, cirrhosis, hepatitis, pancreatitis, and colostomy care. Focus on preprocedure and postprocedure care of the client undergoing a gastrointestinal diagnostic test. Remember that an informed consent is required for any invasive procedure. Focus on diet restrictions before and after the diagnostic test and remember that the gag reflex or bowel sounds must return before allowing a client to consume food or fluids. Pyramid Points also include instructions to the client and family regarding the prevention of gastrointestinal problems and the complications associated with the problem. Focus on teaching the client and family about diet and nutrition specific to the problem, tube and wound care, preventing the transmission of infection such as with hepatitis, and care of a colostomy or ileostomy. Remember that body image disturbances can occur in clients with a gastrointestinal problem. Specific focus relates to the client with a diversion, such as an ileostomy or colostomy; the social isolation issues that can occur; and effective coping strategies.

Client Needs: Learning Objectives

Safe and Effective Care Environment

Consulting with the interprofessional team regarding the client’s care and nutritional status
Ensuring that confidentiality issues related to the gastrointestinal problem are maintained
Ensuring that informed consent for treatments and surgical procedures has been obtained
Establishing priorities of care
Handling infectious drainage and secretions safely
Maintaining standard precautions and other precautions as appropriate
Obtaining referrals for home care and community services
Preventing disease transmission

Health Promotion and Maintenance

Performing physical assessment techniques of the gastrointestinal system
Preventing disease related to the gastrointestinal system
Providing health screening and health promotion programs related to gastrointestinal problems
Teaching related to colostomy or ileostomy care
Teaching related to prescribed dietary and other treatment measures
Teaching related to preventing the transmission of disease

**Psychosocial Integrity**

Assessing coping mechanisms
Considering end-of-life and grief and loss issues
Identifying available support systems
Monitoring for concerns related to body image changes

**Physiological Integrity**

Administering medications as prescribed specific to the gastrointestinal problem
Assessing for signs and symptoms of infectious diseases of the gastrointestinal tract
Assisting with personal hygiene
Monitoring elimination patterns
Monitoring for complications related to tests, procedures, and surgical interventions
Monitoring for fluid and electrolyte imbalances
Monitoring laboratory values related to gastrointestinal problems
Monitoring parenterally administered fluids, including total parenteral nutrition (TPN)
Providing adequate nutrition and oral hydration
Providing care for gastrointestinal tubes
Providing nonpharmacological and pharmacological comfort measures
Providing preprocedure and postprocedure care for diagnostic tests related to the gastrointestinal system
CHAPTER 48

Gastrointestinal Problems

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts

Elimination; Nutrition

I. Anatomy and Physiology
   A. Functions of the gastrointestinal (GI) system
      1. Process food substances
      2. Absorb the products of digestion into the blood
      3. Excrete unabsorbed materials
      4. Provide an environment for microorganisms to synthesize nutrients, such as vitamin K.
      5. For risk factors associated with the GI system, see Box 48-1.
   B. Mouth
      1. Contains the lips, cheeks, palate, tongue, teeth, salivary glands, muscles, and maxillary bones
      2. Saliva contains the enzyme amylase (ptyalin), which aids in digestion.
   C. Esophagus
      1. Collapsible muscular tube about 10 inches (25 cm) long
      2. Carries food from the pharynx to the stomach
   D. Stomach
      1. Contains the cardia, fundus, body, and pylorus
      2. Mucous glands are located in the mucosa and prevent autodigestion by providing an alkaline protective covering.
      3. The lower esophageal (cardiac) sphincter prevents reflux of gastric contents into the esophagus.
      4. The pyloric sphincter regulates the rate of stomach emptying into the small intestine.
      5. Hydrochloric acid kills microorganisms, breaks food into small particles, and provides a chemical environment that facilitates gastric enzyme activation.
      6. Pepsin is the chief coenzyme of gastric juice, which converts proteins into proteases and peptones.
      7. Intrinsic factor comes from parietal cells and is
necessary for the absorption of vitamin B$_{12}$.
8. Gastrin controls gastric acidity.

E. Small intestine
1. The duodenum contains the openings of the bile and pancreatic ducts.
2. The jejunum is about 8 feet (2.4 meters) long.
3. The ileum is about 12 feet (3.7 meters) long.
4. The small intestine terminates in the cecum.

F. Pancreatic intestinal juice enzymes
1. Amylase digests starch to maltose.
2. Maltase reduces maltose to monosaccharide glucose.
3. Lactase splits lactose into galactose and glucose.
4. Sucrase reduces sucrose to fructose and glucose.
5. Nucleases split nucleic acids to nucleotides.
6. Enterokinase activates trypsinogen to trypsin.

G. Large intestine
1. About 5 feet (1.5 meters) long
2. Absorbs water and eliminates wastes
3. Intestinal bacteria play a vital role in the synthesis of some B vitamins and vitamin K.
4. Colon: Includes the ascending, transverse, descending, and sigmoid colons and rectum
5. The ileocecal valve prevents contents of the large intestine from entering the ileum.
6. The internal and external anal sphincters control the anal canal.

H. Peritoneum: Lines the abdominal cavity and forms the mesentery that supports the intestines and blood supply

I. Liver
1. The largest gland in the body, weighing 3 to 4 pounds (1.4 to 1.8 kg)
2. Contains Kupffer cells, which remove bacteria in the portal venous blood
3. Removes excess glucose and amino acids from the portal blood
4. Synthesizes glucose, amino acids, and fats
5. Aids in the digestion of fats, carbohydrates, and proteins
6. Stores and filters blood (200 to 400 mL of blood stored)
7. Stores vitamins A, D, and B and iron
8. The liver secretes bile to emulsify fats (500 to 1000 mL of bile/day).
9. Hepatic ducts
   a. Deliver bile to the gallbladder via the cystic duct and to the duodenum via the common bile duct
   b. The common bile duct opens into the duodenum, with the pancreatic duct at
the ampulla of Vater.
c. The sphincter prevents the reflux of intestinal contents into the common bile duct and pancreatic duct.

J. Gallbladder
1. Stores and concentrates bile and contracts to force bile into the duodenum during the digestion of fats
2. The cystic duct joins the hepatic duct to form the common bile duct.
3. The sphincter of Oddi is located at the entrance to the duodenum.
4. The presence of fatty materials in the duodenum stimulates the liberation of cholecystokinin, which causes contraction of the gallbladder and relaxation of the sphincter of Oddi.

K. Pancreas
1. Exocrine gland
   a. Secretes sodium bicarbonate to neutralize the acidity of the stomach contents that enter the duodenum
   b. Pancreatic juices contain enzymes for digesting carbohydrates, fats, and proteins.
2. Endocrine gland
   a. Secretes glucagon to raise blood glucose levels and secretes somatostatin to exert a hypoglycemic effect
   b. The islets of Langerhans secrete insulin.
   c. Insulin is secreted into the bloodstream and is important for carbohydrate metabolism.

II. Diagnostic Procedures (Box 48-2)
   A. Upper GI tract study (barium swallow)
      1. Description: Examination of the upper GI tract under fluoroscopy after the client drinks barium sulfate
      2. Preprocedure: Withhold foods and fluids for 8 hours prior to the test.
      3. Postprocedure
         a. A laxative may be prescribed.
         b. Instruct the client to increase oral fluid intake to help pass the barium.
         c. Monitor stools for the passage of barium (stools will appear chalky white for 24 to 72 hours postprocedure) because barium can cause a bowel obstruction.

B. Capsule endoscopy
1. Description: A procedure that uses a small wireless camera shaped like a medication capsule that the client swallows; the test will detect bleeding or changes in the lining of the small intestine.

2. The camera travels through the entire digestive tract and sends pictures to a small box that the client wears like a belt; the small box saves the pictures, which are then transferred to a computer for viewing once the test is complete.

3. The client visits the primary health care provider’s (PHCP’s) office in the morning and swallows the capsule, the recording belt is applied by the office staff, and then the client returns at the end of the day so that pictures can be transferred to the computer.

4. Preprocedure: A bowel preparation will be prescribed. The client will need to maintain a clear liquid diet on the evening before the exam; additionally, NPO (nothing by mouth) status is maintained for 3 hours before and after swallowing the capsule (time for NPO status is prescribed by the PHCP but is usually 2 to 3 hours).

C. Gastric analysis

1. Description
   a. Gastric analysis requires the passage of a nasogastric (NG) tube into the stomach to aspirate gastric contents for the analysis of acidity (pH), appearance, and volume; the entire gastric contents are aspirated, and then specimens are collected every 15 minutes for 1 hour.
   b. Medication, such as histamine or pentagastrin, may be administered subcutaneously to stimulate gastric secretions; some medications may produce a flushed feeling.
   c. Esophageal reflux of gastric acid may be diagnosed by ambulatory pH monitoring; a probe is placed just above the lower esophageal sphincter and connected to an external recording device. It provides a computer analysis and graphic display of results.

2. Preprocedure
   a. Fasting for at least 12 hours is required before the test.
   b. Use of tobacco and chewing gum is avoided for 24 hours before the test.
c. Medications that stimulate gastric secretions are withheld for 24 to 48 hours.

3. Postprocedure
   a. Client may resume normal activities.
   b. Refrigerate gastric samples if not tested within 4 hours.

D. Upper GI endoscopy

1. Description
   a. Also known as esophagastroduodenoscopy
   b. Following sedation, an endoscope is passed down the esophagus to view the gastric wall, sphincters, and duodenum; tissue specimens can be obtained.

2. Preprocedure
   a. The client must be NPO for 6 to 8 hours before the test.
   b. A local anesthetic (spray or gargle) is administered along with medication that provides moderate sedation just before the scope is inserted.
   c. Medication may be administered to reduce secretions, and medication may be administered to relax smooth muscle.
   d. The client is positioned on the left side to facilitate saliva drainage and to provide easy access of the endoscope.
   e. Airway patency is monitored during the test, and pulse oximetry is used to monitor oxygen saturation; emergency equipment should be readily available.

3. Postprocedure
   a. Monitor vital signs.
   b. Client must be NPO until the gag reflex returns (1 to 2 hours).
   c. Monitor for signs of perforation (pain, bleeding, unusual difficulty in swallowing, elevated temperature).
   d. Maintain bed rest for the sedated client until alert.
   e. Lozenges, saline gargles, or oral analgesics can relieve a minor sore throat (not given to the client until the gag reflex returns).
E. Fiberoptic colonoscopy

1. Description
   a. Colonoscopy is a fiberoptic endoscopy study in which the lining of the large intestine is visually examined; biopsies and polypectomies can be performed.
   b. Cardiac and respiratory function is monitored continuously during the test.
   c. Colonoscopy is performed with the client lying on the left side with the knees drawn up to the chest; position may be changed during the test to facilitate passing of the scope.

2. Preprocedure
   a. Adequate cleansing of the colon is necessary, as prescribed by the PHCP.
   b. A clear liquid diet is started on the day before the test. Red, orange, and purple (grape) liquids are to be avoided.
   c. Consult with the PHCP regarding medications that must be withheld before the test.
   d. Client is NPO for 4 to 6 hours prior to the test.
   e. Moderate sedation is administered intravenously.
   f. Medication may be administered to relax smooth muscle.

3. Postprocedure
   a. Monitor vital signs.
   b. Provide bed rest until alert.
   c. Monitor for signs of bowel perforation and peritonitis (Box 48-3).
   d. Remind the client that passing flatus, abdominal fullness, and mild cramping are expected for several hours.
   e. Instruct the client to report any bleeding to the PHCP.

The client receiving oral liquid bowel cleaning.
cleansing preparations or enemas is at risk for fluid and electrolyte imbalances.

F. Laparoscopy is performed with a fiberoptic laparoscope that allows direct visualization of organs and structures within the abdomen; biopsies may be obtained.

G. Endoscopic retrograde cholangiopancreatography (ERCP)

1. Description
   a. Examination of the hepatobiliary system is performed via a flexible endoscope inserted into the esophagus to the descending duodenum; multiple positions are required during the procedure to pass the endoscope.
   b. If medication is administered before the procedure, the client is monitored closely for signs of respiratory and central nervous system depression, hypotension, oversedation, and vomiting.

2. Preprocedure
   a. Client is NPO for 6 to 8 hours.
   b. Inquire about previous exposure to contrast media and any sensitivities or allergies.
   c. Moderate sedation is administered.

3. Postprocedure
   a. Monitor vital signs.
   b. Monitor for the return of the gag reflex.
   c. Monitor for signs of perforation or peritonitis (see Box 48-3).

H. Magnetic resonance cholangiopancreatography (MRCP)

1. Description: Uses magnetic resonance to visualize the biliary and pancreatic ducts in a noninvasive way.

2. Preprocedure and postprocedure: see ERCP

I. Endoscopic ultrasonography

1. Description: Provides images of the GI wall and digestive organs.

2. Preprocedure and postprocedure: Care is similar to that implemented for endoscopy.

Following endoscopic procedures, monitor for the return of the gag reflex before giving the client any oral substance. If the gag reflex
J. Computed tomography (CT) scan
1. Description
   a. Noninvasive cross-sectional view that can detect tissue densities in the abdomen, including in the liver, spleen, pancreas, and biliary tree.
   b. Can be performed with or without contrast medium.

2. Preprocedure
   a. Client is NPO for at least 4 hours.
   b. If contrast medium will be used, assess for previous sensitivities and allergies.

3. Postprocedure: No specific care is required.

K. Paracentesis
1. Description and preprocedure (see Priority Nursing Actions)

**Priority Nursing Actions**

Paracentesis

1. Ensure that the client understands the procedure and that informed consent has been obtained.
2. Obtain vital signs, including weight, and assist the client to void.
3. Position the client upright.
4. Assist the primary health care provider (PHCP), monitor vital signs, and provide comfort and support during the procedure.
5. Apply a dressing to the site of puncture.
6. Monitor vital signs, especially blood pressure and pulse, because these parameters provide information on rapid vasodilation postparacentesis; weigh the client postprocedure, and maintain the client on bed rest.
7. Measure the amount of fluid removed.
8. Label and send the fluid for laboratory analysis.
9. Document the event, client’s response, and appearance and amount of fluid removed.

**Reference**

2. Postprocedure
   a. Monitor vital signs.
   b. Measure fluid collected, describe, and record.
   c. Label fluid samples and send to the laboratory for analysis.
   d. Apply a dry sterile dressing to the insertion site; monitor the site for bleeding.
   e. Measure abdominal girth and weight.
f. Monitor for hypovolemia, electrolyte loss, mental status changes, or encephalopathy.
g. Monitor for hematuria caused by bladder trauma.
h. Instruct the client to notify the PHCP if the urine becomes bloody, pink, or red.

The rapid removal of fluid from the abdominal cavity during paracentesis leads to decreased abdominal pressure, which can cause vasodilation and resultant shock; therefore, heart rate and blood pressure must be monitored closely.

L. Liver biopsy

1. Description: A needle is inserted through the abdominal wall to the liver to obtain a tissue sample for biopsy and microscopic examination.

2. Preprocedure
   a. Assess results of coagulation tests (prothrombin time, partial thromboplastin time, platelet count).
   b. Administer a sedative as prescribed.
   c. Note that the client is placed in the supine or left lateral position during the procedure to expose the right side of the upper abdomen.

3. Postprocedure
   a. Assess vital signs.
   b. Assess biopsy site for bleeding.
   c. Monitor for peritonitis (see Box 48-3).
   d. Maintain bed rest for several hours as prescribed.
   e. Place the client on the right side with a pillow under the costal margin for 2 hours to decrease the risk of bleeding, and instruct the client to avoid coughing and straining.
   f. Instruct the client to avoid heavy lifting and strenuous exercise for 1 week.

M. Stool specimens

1. Testing of stool specimens includes inspecting the specimen for consistency and color and testing for occult blood.
2. Tests for fecal urobilinogen, fat, nitrogen, parasites,
Pathogens, food substances, and other substances may be performed; these tests require that the specimen be sent to the laboratory.

3. Random specimens are sent promptly to the laboratory.

4. Quantitative 24- to 72-hour collections must be kept refrigerated until they are taken to the laboratory.

5. Some specimens require that a certain diet be followed or that certain medications be withheld; check agency guidelines regarding specific procedures.

N. Urea breath test

1. The urea breath test detects the presence of *Helicobacter pylori*, the bacteria that cause peptic ulcer disease.

2. The client consumes a capsule of carbon-labeled urea and provides a breath sample 10 to 20 minutes later.

3. Certain medications may need to be avoided before testing. These may include antibiotics or bismuth subsalicylate for 1 month before the test; sucralfate and omeprazole for 1 week before the test; and cimetidine, famotidine, ranitidine, and nizatidine for 24 hours before breath testing.

4. *H. pylori* can also be detected by assessing serum antibody levels.

O. Esophageal pH testing for gastroesophageal reflux disease

1. Used to diagnose or evaluate the treatment for heartburn or reflux disease

2. A probe is inserted into the nostril and is situated in the esophagus.

3. pH is tested over a period of 24 to 48 hours.

P. Liver and pancreas laboratory studies

1. Liver enzyme levels (alkaline phosphatase [ALP], aspartate aminotransferase [AST], and alanine aminotransferase [ALT]) are elevated with liver damage or biliary obstruction. Normal reference intervals: ALP, 38-126 U/L (0.65-2.14 µkat/L); AST, 0 to 35 U/L (0 to 35 U/L); ALT, 4 to 36 U/L (4 to 36 U/L).

2. Prothrombin time is prolonged with liver damage. Normal reference interval: 11 to 12.5 seconds.

3. The serum ammonia level assesses the ability of the liver to deaminate protein byproducts. Normal reference interval: 10 to 80 mcg/dL (6 to 47 mcmol/L).

4. An increase in cholesterol level indicates pancreatitis or biliary obstruction. Normal reference interval: less than 200 mg/dL (less than 5.0 mmol/L).

5. An increase in bilirubin level indicates liver damage or biliary obstruction. Normal reference intervals: total, 0.3 to 1.0 mg/dL (5.1 to 17 mcmol/L); indirect, 0.2 to
0.8 mg/dL (3.4 to 12 mcmol/L); direct, 0.1 to 0.3 mg/dL (1.7 to 5.1 mcmol/L).

6. Increased values for amylase and lipase levels indicate pancreatitis. Normal reference intervals: amylase, 60 to 120 Somogyi units/dL (100 to 300 U/L); lipase, 0 to 160 U/L (0 to 160 U/L).

III. Assessment: See Chapter 12 for abdominal assessment techniques.
IV. Gastrointestinal Tubes: See Chapter 69 for information regarding these tubes.
V. Gastroesophageal Reflux Disease
   A. Description
      1. The backflow of gastric and duodenal contents into the esophagus.
      2. The reflux is caused by an incompetent lower esophageal sphincter (LES), pyloric stenosis, or motility disorder.
   B. Assessment
      1. Heartburn, epigastric pain
      2. Dyspepsia
      3. Nausea, regurgitation
      4. Pain and difficulty with swallowing
      5. Hypersalivation
   C. Interventions
      1. Instruct the client to avoid factors that decrease LES pressure or cause esophageal irritation, such as peppermint, chocolate, coffee, fried or fatty foods, carbonated beverages, alcoholic beverages, and cigarette smoking.
      2. Instruct the client to eat a low-fat, high-fiber diet and to avoid eating and drinking 2 hours before bedtime and wearing tight clothes; also, elevate the head of the bed on 6- to 8-inch (15 to 20 cm) blocks.
      3. Avoid the use of anticholinergics, which delay stomach emptying; also, nonsteroidal anti-inflammatory medications (NSAIDs) and other medications that contain acetylsalicylic acid need to be avoided.
      4. Instruct the client regarding prescribed medications, such as antacids, H₂-receptor antagonists, or proton pump inhibitors.
      5. Instruct the client regarding the administration of prokinetic medications, if prescribed, which accelerate gastric emptying.
      6. Surgery may be required in extreme cases when medical management is unsuccessful; this involves a fundoplication (wrapping a portion of the gastric
fundus around the sphincter area of the esophagus); surgery may be performed by laparoscopy.

VI. Gastritis

A. Description
   1. Inflammation of the stomach or gastric mucosa
   2. Acute gastritis is caused by the ingestion of food contaminated with disease-causing microorganisms or food that is irritating or too highly seasoned, the overuse of aspirin or other NSAIDs, excessive alcohol intake, bile reflux, or radiation therapy.
   3. Chronic gastritis is caused by benign or malignant ulcers or by the bacteria \textit{H. pylori}, and also may be caused by autoimmune diseases, dietary factors, medications, alcohol, smoking, or reflux.

B. Assessment (Box 48-4)

C. Interventions
   1. Acute gastritis: Food and fluids may be withheld until symptoms subside; afterward, and as prescribed, ice chips can be given, followed by clear liquids, and then solid food.
   2. Monitor for signs of hemorrhagic gastritis such as hematemesis, tachycardia, and hypotension, and notify the PHCP if these signs occur.
   3. Instruct the client to avoid irritating foods, fluids, and other substances, such as spicy and highly seasoned foods, caffeine, alcohol, and nicotine.
   4. Instruct the client in the use of prescribed medications, such as antibiotics to treat \textit{H. pylori}, and antacids.
   5. Provide the client with information about the importance of vitamin B\textsubscript{12} injections if a deficiency is present.

VII. Peptic Ulcer Disease

A. Description
   1. A peptic ulcer is an ulceration in the mucosal wall of the stomach, pylorus, duodenum, or esophagus in portions accessible to gastric secretions; erosion may extend through the muscle.
   2. The ulcer may be referred to as \textit{gastric, duodenal, or esophageal}, depending on its location.
   3. The most common peptic ulcers are gastric ulcers and duodenal ulcers.

B. Gastric ulcers
   1. Description
      a. A gastric ulcer involves ulceration of the mucosal lining that extends to the submucosal layer of the stomach.
b. Predisposing factors include stress, smoking, the use of corticosteroids, NSAIDs, alcohol, history of gastritis, family history of gastric ulcers, or infection with *H. pylori*.

c. Complications include hemorrhage, perforation, and pyloric obstruction.

2. Assessment (Box 48-5)

3. Interventions

- a. Monitor vital signs and for signs of bleeding.
- b. Administer small, frequent bland feedings during the active phase.
- c. Administer H$_2$-receptor antagonists or proton pump inhibitors as prescribed to decrease the secretion of gastric acid.
- d. Administer antacids as prescribed to neutralize gastric secretions.
- e. Administer anticholinergics as prescribed to reduce gastric motility.
- f. Administer mucosal barrier protectants as prescribed 1 hour before each meal.
- g. Administer prostaglandins as prescribed for their protective and antisecretory actions.

4. Client education

- a. Avoid consuming alcohol and substances that contain caffeine or chocolate.
- b. Avoid smoking.
- c. Avoid aspirin or NSAIDs.
- d. Obtain adequate rest and reduce stress.

5. Interventions during active bleeding

- a. Monitor vital signs closely.
- b. Assess for signs of dehydration, hypovolemic shock, sepsis, and respiratory insufficiency.
- c. Maintain NPO status and administer intravenous (IV) fluid replacement as prescribed; monitor intake and output.
- d. Monitor hemoglobin and hematocrit.
e. Administer blood transfusions as prescribed.
f. Prepare to assist with administering medications as prescribed to induce vasoconstriction and reduce bleeding.

6. Surgical interventions
   a. Total gastrectomy: Removal of the stomach with attachment of the esophagus to the jejunum or duodenum; also called esophagojejunostomy or esophagoduodenostomy
   b. Vagotomy: Surgical division of the vagus nerve to eliminate the vagal impulses that stimulate hydrochloric acid secretion in the stomach
   c. Gastric resection: Removal of the lower half of the stomach and usually includes a vagotomy; also called antrectomy
   d. Gastroduodenostomy: Partial gastrectomy, with the remaining segment anastomosed to the duodenum; also called Billroth I (Fig. 48-1)
   e. Gastrojejunostomy: Partial gastrectomy, with the remaining segment anastomosed to the jejunum; also called Billroth II (Fig. 48-2)
   f. Pyloroplasty: Enlargement of the pylorus to prevent or decrease pyloric obstruction, thereby enhancing gastric emptying

7. Postoperative interventions
   a. Monitor vital signs.
      b. Place in a Fowler’s position for comfort and to promote drainage.
      c. Administer fluids and electrolyte replacements intravenously as prescribed; monitor intake and output.
   d. Assess bowel sounds.
   e. Monitor NG suction as prescribed.
   f. Maintain NPO status as prescribed for 1 to 3 days until peristalsis returns.
   g. Progress the diet from NPO to sips of clear water to 6 small bland meals a day, as prescribed when bowel sounds
Monitor for postoperative complications of hemorrhage, **dumping syndrome**, diarrhea, hypoglycemia, and vitamin B\textsubscript{12} deficiency.

**Following gastric surgery, do not irrigate or remove the NG tube unless specifically prescribed because of the risk for disruption of the gastric sutures. Monitor closely to ensure proper functioning of the NG tube to prevent strain on the anastomosis site. Contact the surgeon if the tube is not functioning properly.**

C. Duodenal ulcers

1. **Description**
   a. A duodenal ulcer is a break in the mucosa of the duodenum.
   b. Risk factors and causes include infection with *H. pylori*; alcohol intake; smoking; stress; caffeine; and the use of aspirin, corticosteroids, and NSAIDs.
   c. Complications include bleeding, perforation, gastric outlet obstruction, and intractable disease.

2. **Assessment** (see Box 48-5)

3. **Interventions**
   a. Monitor vital signs.
   b. Instruct the client about a bland diet, with small, frequent meals.
   c. Provide for adequate rest.
   d. Encourage the cessation of smoking.
   e. Instruct the client to avoid alcohol intake; caffeine; and the use of aspirin, corticosteroids, and NSAIDs.
   f. Administer medications to treat *H. pylori* and antacids to neutralize acid secretions as prescribed.
   g. Administer H\textsubscript{2}-receptor antagonists or proton pump inhibitors as prescribed to block the secretion of acid.

4. **Surgical interventions:** Surgery is performed only if
the ulcer is unresponsive to medications or if hemorrhage, obstruction, or perforation occurs.

D. Dumping syndrome
1. Description: The rapid emptying of the gastric contents into the small intestine that occurs following gastric resection

2. Assessment
   a. Symptoms occurring 30 minutes after eating
   b. Nausea and vomiting
   c. Feelings of abdominal fullness and abdominal cramping
   d. Diarrhea
   e. Palpitations and tachycardia
   f. Perspiration
   g. Weakness and dizziness
   h. Borborygmi (loud gurgling sounds resulting from bowel hypermotility)

3. Client education (Box 48-6)

VIII. Vitamin B₁₂ Deficiency: See Chapter 44 for more information.

IX. Bariatric Surgery
   A. Description
   1. Surgical reduction of gastric capacity or absorptive ability that may be performed on a client with morbid obesity to produce long-term weight loss
   2. Surgery may be performed by laparoscopy; the decision is based on the client’s weight, body build, history of abdominal surgery, and current medical disorders.
   3. Obese clients are at increased postoperative risk for pulmonary and thromboembolic complications and death.
   4. Surgery can prevent the complications of obesity, such as diabetes mellitus, hypertension and other cardiovascular disorders, or sleep apnea.
   5. The client needs to agree to modify her or his lifestyle, lose weight and keep the weight off, and obtain support from available community resources such as the American Obesity Association, American Society of Bariatric Surgery, or Overeaters Anonymous.

B. Types (Fig. 48-3)
C. Postoperative interventions
   1. Care is similar to that for the client undergoing laparoscopic or abdominal surgery.
   2. As prescribed, if the client can tolerate water, clear liquids are introduced slowly in 1-ounce (30 mL) cups for each serving once bowel sounds have returned and the client passes flatus.
   3. As prescribed, clear fluids are followed by puréed foods, juices, thin soups, and milk 24 to 48 hours after clear fluids are tolerated (the diet is usually limited to liquids or puréed foods for 6 weeks); then the diet is progressed to nutrient-dense regular food.

D. Client teaching points about diet (Box 48-7)

X. Gastric Cancer: See Chapter 44 for more information.

XI. Hiatal Hernia

A. Description
   1. A **hiatal hernia** is also known as *esophageal* or *diaphragmatic hernia*.
   2. A portion of the stomach herniates through the diaphragm and into the thorax.
   3. Herniation results from weakening of the muscles of the diaphragm and is aggravated by factors that increase abdominal pressure such as pregnancy, ascites, obesity, tumors, and heavy lifting.
   4. Complications include ulceration, hemorrhage, regurgitation and aspiration of stomach contents, strangulation, and incarceration of the stomach in the chest with possible necrosis, peritonitis, and mediastinitis.

B. Assessment
   1. Heartburn
   2. Regurgitation or vomiting
   3. Dysphagia
   4. Feeling of fullness

C. Interventions
   1. Medical and surgical management are similar to those for gastroesophageal reflux disease.
   2. Provide small frequent meals and limit the amount of liquids taken with meals.
   3. Advise the client not to recline for 1 hour after eating.
   4. Avoid anticholinergics, which delay stomach emptying.

XII. Cholecystitis

A. Description
   1. Inflammation of the gallbladder that may occur as an
acute or chronic process
2. Acute inflammation is associated with gallstones (cholelithiasis).
3. Chronic **cholecystitis** results when inefficient bile emptying and gallbladder muscle wall disease cause a fibrotic and contracted gallbladder.
4. Acalculous cholecystitis occurs in the absence of gallstones and is caused by bacterial invasion via the lymphatic or vascular system.

B. Assessment
1. Nausea and vomiting
2. Indigestion
3. Belching
4. Flatulence
5. Epigastric pain that radiates to the right shoulder or scapula
6. Pain localized in the right upper quadrant and triggered by a high-fat or high-volume meal
7. Guarding, rigidity, and rebound tenderness
8. Mass palpated in the right upper quadrant
9. **Murphy’s sign** (cannot take a deep breath when the examiner’s fingers are passed below the hepatic margin because of pain)
10. Elevated temperature
11. Tachycardia
12. Signs of dehydration

C. Biliary obstruction (choledolithiasis)
1. Jaundice
2. Dark orange and foamy urine
3. Steatorrhea and clay-colored feces
4. Pruritus

D. Interventions
1. Maintain NPO status during nausea and vomiting episodes.
2. Maintain NG decompression as prescribed for severe vomiting.
3. Administer antiemetics as prescribed for nausea and vomiting.
4. Administer analgesics as prescribed to relieve pain and reduce spasm.
5. Administer antispasmodics (anticholinergics) as prescribed to relax smooth muscle.
6. Instruct the client with chronic cholecystitis to eat
small, low-fat meals.
7. Instruct the client to avoid gas-forming foods.
8. Prepare the client for nonsurgical and surgical procedures as prescribed.

E. Surgical interventions
1. **Cholecystectomy** is the removal of the gallbladder.
2. **Choledocholithotomy** requires incision into the common bile duct to remove the stone.
3. Surgical procedures may be performed by laparoscopy.

F. Postoperative interventions
1. Monitor for respiratory complications caused by pain at the incisional site.
2. Encourage coughing and deep breathing.
3. Encourage early ambulation.
4. Instruct the client about splinting the abdomen to prevent discomfort during coughing.
5. Administer antiemetics as prescribed for nausea and vomiting.
6. Administer analgesics as prescribed for pain relief.
7. Maintain NPO status and NG tube suction as prescribed.
8. Advance diet from clear liquids to solids when prescribed and as tolerated by the client.
9. Maintain and monitor drainage from the T-tube, if present (Box 48-8).

XIII. Cirrhosis
A. Description
1. A chronic, progressive disease of the liver characterized by diffuse degeneration and destruction of hepatocytes.
2. Repeated destruction of hepatic cells causes the formation of scar tissue.
3. Cirrhosis has many causes and is due to chronic damage and injury to liver cells; the most common are chronic hepatitis C, alcoholism, **nonalcoholic fatty liver disease (NAFLD)**, and **nonalcoholic steatohepatitis (NASH)**.

B. Complications
1. Portal hypertension: A persistent increase in pressure in the portal vein that develops as a result of obstruction to flow.
2. **Ascites**
a. Accumulation of fluid in the peritoneal cavity that results from venous congestion of the hepatic capillaries
b. Capillary congestion leads to plasma leaking directly from the liver surface and portal vein.

3. Bleeding esophageal varices: Fragile, thin-walled, distended esophageal veins that become irritated and rupture

4. Coagulation defects
   a. Decreased synthesis of bile fats in the liver prevents the absorption of fat-soluble vitamins.
   b. Without vitamin K and clotting factors II, VII, IX, and X, the client is prone to bleeding.

5. Jaundice: Occurs because the liver is unable to metabolize bilirubin and because the edema, fibrosis, and scarring of the hepatic bile ducts interfere with normal bile and bilirubin secretion

6. Portal systemic encephalopathy: End-stage hepatic failure characterized by altered level of consciousness, neurological symptoms, impaired thinking, and neuromuscular disturbances; caused by failure of the diseased liver to detoxify neurotoxic agents such as ammonia

7. Hepatorenal syndrome
   a. Progressive renal failure associated with hepatic failure
   b. Characterized by a sudden decrease in urinary output, elevated blood urea nitrogen and creatinine levels, decreased urine sodium excretion, and increased urine osmolarity

C. Assessment (Fig. 48-4)

D. Interventions

1. Elevate the head of the bed to minimize shortness of breath.
2. If ascites and edema are absent and the client does not exhibit signs of impending coma, a high-protein diet supplemented with vitamins is prescribed.
3. Provide supplemental vitamins (B complex; vitamins A, C, and K; folic acid; and thiamine) as prescribed.
4. Restrict sodium intake and fluid intake as prescribed.
5. Initiate enteral feedings or parenteral nutrition as
prescribed.
6. Administer diuretics as prescribed to treat ascites.
7. Monitor intake and output and electrolyte balance.
8. Weigh client and measure abdominal girth daily (Fig. 48-5).
9. Monitor level of consciousness; assess for precoma state (tremors, delirium).
10. Monitor for asterixis, a coarse tremor characterized by rapid, nonrhythmic extensions and flexions in the wrist and fingers (Fig. 48-6).
11. Monitor for fetor hepaticus, the fruity, musty breath odor of severe chronic liver disease.
12. Maintain gastric intubation to assess bleeding or esophagogastric balloon tamponade to control bleeding varices if prescribed.
13. Administer blood products as prescribed.
14. Monitor coagulation laboratory results; administer vitamin K if prescribed.
15. Administer antacids as prescribed.
16. Administer lactulose as prescribed, which decreases the pH of the bowel, decreases production of ammonia by bacteria in the bowel, and facilitates the excretion of ammonia.
17. Administer antibiotics as prescribed to inhibit protein synthesis in bacteria and decrease the production of ammonia.
18. Avoid medications such as opioids, sedatives, and barbiturates and any hepatotoxic medications or substances.
19. Instruct the client about the importance of abstinence of alcohol intake.
20. Prepare the client for paracentesis to remove abdominal fluid.
21. Prepare the client for surgical shunting procedures if prescribed to divert fluid from ascites into the venous system.

XIV. Esophageal Varices
A. Description
1. Dilated and tortuous veins in the submucosa of the esophagus
2. Caused by portal hypertension, often associated with liver cirrhosis; are at high risk for rupture if portal circulation pressure rises
3. Bleeding varices are an emergency.
4. The goal of treatment is to control bleeding, prevent complications, and prevent the recurrence of bleeding.

B. Assessment
1. Hematemesis
2. Melena
3. Ascites
4. Jaundice
5. Hepatomegaly and splenomegaly
6. Dilated abdominal veins
7. Signs of shock

*Rupture and resultant hemorrhage of esophageal varices is the primary concern, because it is a life-threatening situation.*

C. Interventions

1. Monitor vital signs.
2. Elevate the head of the bed.
3. Monitor for orthostatic hypotension.
4. Monitor lung sounds and for the presence of respiratory distress.
5. Administer oxygen as prescribed to prevent tissue hypoxia.
6. Monitor level of consciousness.
7. Maintain NPO status.
8. Administer fluids intravenously as prescribed to restore fluid volume and electrolyte imbalances; monitor intake and output.
9. Monitor hemoglobin and hematocrit values and coagulation factors.
10. Administer blood transfusions or clotting factors as prescribed.
11. Assist in inserting an NG tube or a balloon tamponade as prescribed; balloon tamponade is not used frequently because it is very uncomfortable for the client and its use is associated with complications.
12. Prepare to assist with administering medications to induce vasoconstriction and reduce bleeding.
13. Instruct the client to avoid activities that will initiate vasovagal responses.
14. Prepare the client for endoscopic procedures or surgical procedures as prescribed.

D. Endoscopic injection (sclerotherapy)

1. The procedure involves the injection of a sclerosing agent into and around bleeding varices.
2. Complications include chest pain, pleural effusion, aspiration pneumonia, esophageal stricture, and perforation of the esophagus.

E. Endoscopic variceal ligation

1. The procedure involves ligation of the varices with an
elastic rubber band.

2. Sloughing, followed by superficial ulceration, occurs in the area of ligation within 3 to 7 days.

F. Shunting procedures

1. Description: Shunt blood away from the esophageal varices

2. Portacaval shunting involves anastomosis of the portal vein to the inferior vena cava, diverting blood from the portal system to the systemic circulation (Fig. 48-7).

3. Distal splenorenal shunt (see Fig. 48-7)

   a. The shunt involves anastomosis of the splenic vein to the left renal vein.
   b. The spleen conducts blood from the high-pressure varices to the low-pressure renal vein.

4. Mesocaval shunting involves a side anastomosis of the superior mesenteric vein to the proximal end of the inferior vena cava.

5. Transjugular intrahepatic portosystemic shunt (TIPS)

   a. This procedure uses the normal vascular anatomy of the liver to create a shunt with the use of a metallic stent.
   b. The shunt is between the portal and systemic venous system in the liver and is aimed at relieving portal hypertension.

XV. Hepatitis

A. Description

1. Inflammation of the liver caused by a virus, bacteria, or exposure to medications or hepatotoxins

2. The goals of treatment include resting the inflamed liver to reduce metabolic demands and increasing the blood supply, thus promoting cellular regeneration and preventing complications.

B. Types of hepatitis include hepatitis A virus (HAV), hepatitis B virus (HBV), hepatitis C virus (HCV), hepatitis D virus (HDV), and hepatitis E virus (HEV).

C. Assessment and stages of viral hepatitis (Box 48-9)

XVI. Hepatitis A

A. Description: Formerly known as infectious hepatitis

B. Individuals at increased risk

1. Crowded conditions (e.g., day care, nursing home)

2. Exposure to poor sanitation

C. Transmission
1. Fecal-oral route
2. Person-to-person contact
3. Parenteral
4. Contaminated fruits or vegetables, or uncooked shellfish
5. Contaminated water or milk
6. Poorly washed utensils

D. Incubation and infectious period
   1. Incubation period is 2 to 6 weeks.
   2. Infectious period is 2 to 3 weeks before and 1 week after development of jaundice.

E. Testing
   1. Infection is established by the presence of HAV antibodies (anti-HAV) in the blood.
   2. Immunoglobulin M (IgM) and immunoglobulin G (IgG) are normally present in the blood, and increased levels indicate infection and inflammation.
   3. Ongoing inflammation of the liver is evidenced by the presence of elevated levels of IgM antibodies, which persist in the blood for 4 to 6 weeks.
   4. Previous infection is indicated by the presence of elevated levels of IgG antibodies.

F. Complication: Fulminant (severe acute and often fatal) hepatitis

G. Prevention
   1. Strict hand washing
   2. Stool and needle precautions
   3. Treatment of municipal water supplies
   4. Serological screening of food handlers
   5. Hepatitis A vaccine: Two doses are needed at least 6 months apart for lasting protection. For additional information, refer to http://www.cdc.gov/vaccines/hcp/vis/vis-statements/hep-a.html
   6. Immune globulin: For individuals exposed to HAV who have never received the hepatitis A vaccine; administer immune globulin during the period of incubation and within 2 weeks of exposure.
   7. Immune globulin and hepatitis A vaccine are recommended for household members and sexual contacts of individuals with hepatitis A.
   8. Preexposure prophylaxis with immune globulin is recommended to individuals traveling to countries with poor or uncertain sanitation conditions.

⚠️ Strict and frequent hand washing is key to preventing the
spread of all types of hepatitis.

XVII. Hepatitis B

A. Description
1. Hepatitis B is nonseasonal.
2. All age groups can be affected.

B. Individuals at increased risk
1. IV drug users
2. Clients undergoing long-term hemodialysis
3. Health care personnel

C. Transmission
1. Blood or body fluid contact
2. Infected blood products
3. Infected saliva or semen
4. Contaminated needles
5. Sexual contact
6. Parenteral
7. Perinatal period
8. Blood or body fluid contact at birth

D. Incubation period: 6 to 24 weeks

E. Testing
1. Infection is established by the presence of hepatitis B antigen–antibody systems in the blood.
2. The presence of hepatitis B surface antigen (HBsAg) is the serological marker establishing the diagnosis of hepatitis B.
3. The client is considered infectious if these antigens are present in the blood.
4. If the serological marker (HBsAg) is present after 6 months, it indicates a carrier state or chronic hepatitis.
5. Normally, the serological marker (HBsAg) level declines and disappears after the acute hepatitis B episode.
6. The presence of antibodies to HBsAg (anti-HBs) indicates recovery and immunity to hepatitis B.
7. Hepatitis B early antigen (HBeAg) is detected in the blood about 1 week after the appearance of HBsAg, and its presence determines the infective state of the client.

F. Complications
1. Fulminant hepatitis
2. Chronic liver disease
3. Cirrhosis
4. Primary hepatocellular carcinoma

G. Prevention
1. Strict hand washing
2. Screening blood donors
3. Testing of all pregnant women
4. Needle precautions
5. Avoiding intimate sexual contact and contact with body fluids if test for HBsAg is positive.
6. Hepatitis B vaccine: Adult and pediatric forms; there is also an adult vaccine that protects against hepatitis A and B.
7. Hepatitis B immune globulin is for individuals exposed to HBV through sexual contact or through the percutaneous or transmucosal routes who have never had hepatitis B and have never received hepatitis B vaccine.

XVIII. Hepatitis C
A. Description
1. HCV infection occurs year-round.
2. Infection can occur in any age group.
3. Infection with HCV is common among IV drug users and is the major cause of posttransfusion hepatitis.
4. Risk factors are similar to those for HBV, because hepatitis C is also transmitted parenterally.
B. Individuals at increased risk
1. Parenteral drug users
2. Clients receiving frequent transfusions
3. Health care personnel
C. Transmission: Same as for HBV, primarily through blood
D. Incubation period: 5 to 10 weeks
E. Testing: Anti-HCV is the antibody to HCV and is measured to detect chronic states of hepatitis C.
F. Complications
1. Chronic liver disease
2. Cirrhosis
3. Primary hepatocellular carcinoma
G. Prevention
1. Strict hand washing
2. Needle precautions
3. Screening of blood donors

XIX. Hepatitis D
A. Description
1. Hepatitis D is common in the Mediterranean and Middle Eastern areas.
2. Hepatitis D occurs with hepatitis B and causes infection only in the presence of active HBV infection.
3. Coinfection with the delta agent (HDV) intensifies the acute symptoms of hepatitis B.
4. Transmission and risk of infection are the same as for HBV, via contact with blood and blood products.

5. Prevention of HBV infection with vaccine also prevents HDV infection, because HDV depends on HBV for replication.

B. High-risk individuals
   1. Drug users
   2. Clients receiving hemodialysis
   3. Clients receiving frequent blood transfusions

C. Transmission: Same as for HBV
D. Incubation period: 7 to 8 weeks
E. Testing: Serological HDV determination is made by detection of the hepatitis D antigen (HDAg) early in the course of the infection and by detection of anti-HDV antibody in the later disease stages.

F. Complications
   1. Chronic liver disease
   2. Fulminant hepatitis

G. Prevention: Because hepatitis D must coexist with hepatitis B, the precautions that help prevent hepatitis B are also useful in preventing delta hepatitis.

XX. Hepatitis E
A. Description
   1. Hepatitis E is a waterborne virus.
   2. Hepatitis E is prevalent in areas where sewage disposal is inadequate or where communal bathing in contaminated rivers is practiced.
   3. Risk of infection is the same as for HAV.
   4. Infection with HEV presents as a mild disease except in infected women in the third trimester of pregnancy, who have a high mortality rate.

B. Individuals with increased risk
   1. Travelers to countries that have a high incidence of hepatitis E, such as India, Burma (Myanmar), Afghanistan, Algeria, and Mexico
   2. Eating or drinking of food or water contaminated with the virus

C. Transmission: Same as for HAV
D. Incubation period: 2 to 9 weeks
E. Testing: Specific serological tests for HEV include detection of IgM and IgG antibodies to hepatitis E (anti-HEV).
F. Complications
1. High mortality rate in pregnant women
2. Fetal demise

G. Prevention

1. Strict hand washing
2. Treatment of water supplies and sanitation measures

XXI. Client and Family Home Care Instructions for Hepatitis: See Box 48-10

XXII. Pancreatitis

A. Description

1. Acute or chronic inflammation of the pancreas, with associated escape of pancreatic enzymes into surrounding tissue
2. Acute pancreatitis occurs suddenly as 1 attack or can be recurrent, with resolutions.
3. Chronic pancreatitis is a continual inflammation and destruction of the pancreas, with scar tissue replacing pancreatic tissue.
4. Precipitating factors include trauma, the use of alcohol, biliary tract disease, viral or bacterial disease, hyperlipidemia, hypercalcemia, cholelithiasis, hyperparathyroidism, ischemic vascular disease, and peptic ulcer disease.

B. Acute pancreatitis

1. Assessment

   a. Abdominal pain, including a sudden onset at a midepigastric or left upper quadrant location with radiation to the back
   b. Pain aggravated by a fatty meal, alcohol, or lying in a recumbent position
   c. Abdominal tenderness and guarding
   d. Nausea and vomiting
   e. Weight loss
   f. Absent or decreased bowel sounds
   g. Elevated white blood cell count and elevated glucose, bilirubin, alkaline phosphatase, and urinary amylase levels
   h. Elevated serum lipase and amylase levels
   i. Cullen’s sign
   j. Turner’s sign
Cullen’s sign is the discoloration of the abdomen and periumbilical area. Turner’s sign is the bluish discoloration of the flanks. Both signs are indicative of pancreatitis.

2. Interventions
   a. Withhold food and fluid during the acute period and maintain hydration with IV fluids as prescribed.
   b. Administer parenteral nutrition for severe nutritional depletion.
   c. Administer supplemental preparations and vitamins and minerals to increase caloric intake if prescribed.
   d. An NG tube may be inserted if the client is vomiting or has biliary obstruction or paralytic ileus.
   e. Administer opiates as prescribed for pain.
   f. Administer H$_2$-receptor antagonists or proton pump inhibitors as prescribed to decrease hydrochloric acid production and prevent activation of pancreatic enzymes.
   g. Instruct the client in the importance of avoiding alcohol.
   h. Instruct the client in the importance of follow-up visits with the PHCP.
   i. Instruct the client to notify the PHCP if acute abdominal pain, jaundice, clay-colored stools, or dark-colored urine develops.

C. Chronic pancreatitis
   1. Assessment
      a. Abdominal pain and tenderness
      b. Left upper quadrant mass
      c. Steatorrhea and foul-smelling stools that may increase in volume as pancreatic insufficiency increases
      d. Weight loss
      e. Muscle wasting
      f. Jaundice
      g. Signs and symptoms of diabetes
mellitus

2. Interventions

a. Instruct the client in the prescribed dietary measures (fat and protein intake may be limited).
b. Instruct the client to avoid heavy meals.
c. Instruct the client about the importance of avoiding alcohol.
d. Provide supplemental preparations and vitamins and minerals to increase caloric intake.
e. Administer pancreatic enzymes as prescribed to aid in the digestion and absorption of fat and protein.
f. Administer insulin or oral hypoglycemic medications as prescribed to control diabetes mellitus, if present.
g. Instruct the client in the use of pancreatic enzyme medications.
h. Instruct the client in the treatment plan for glucose management.
i. Instruct the client to notify the PHCP if increased steatorrhea, abdominal distention or cramping, or skin breakdown develops.
j. Instruct the client in the importance of follow-up visits.

XXIII. Pancreatic Tumors, Intestinal Tumors, and Bowel Obstructions: See Chapter 44 for more information.

XXIV. Irritable Bowel Syndrome (IBS)
A. Description

1. Functional disorder characterized by chronic or recurrent diarrhea, constipation, and/or abdominal pain and bloating
2. Cause is unclear but may be influenced by environmental, immunological, genetic, hormonal, and stress factors

B. Interventions

1. Increase dietary fiber.
2. Drink 8 to 10 cups of liquids per day.
3. Medication therapy: Depends on the predominant symptoms of IBS (antidiarrheals versus bulk-forming laxatives; lubiprostone or linaclotide for constipation-predominant IBS and alosetron for diarrhea-predominant IBS)

XXV. Ulcerative Colitis
A. Description
1. An ulcerative and inflammatory disease of the bowel that results in poor absorption of nutrients.
2. Commonly begins in the rectum and spreads upward toward the cecum.
3. The colon becomes edematous and may develop bleeding lesions and ulcers; the ulcers may lead to perforation.
4. Scar tissue develops and causes loss of elasticity and loss of the ability to absorb nutrients.
5. Colitis is characterized by various periods of remissions and exacerbations.
6. Acute ulcerative colitis results in vascular congestion, hemorrhage, edema, and ulceration of the bowel mucosa.
7. Chronic ulcerative colitis causes muscular hypertrophy, fat deposits, and fibrous tissue, with bowel thickening, shortening, and narrowing.

B. Assessment
1. Anorexia
2. Weight loss
3. Malaise
4. Abdominal tenderness and cramping
5. Severe diarrhea that may contain blood and mucus
6. Malnutrition, dehydration, and electrolyte imbalances
7. Anemia
8. Vitamin K deficiency

C. Interventions
1. Acute phase: Maintain NPO status and administer fluids and electrolytes intravenously or via parenteral nutrition as prescribed.
2. Restrict the client’s activity to reduce intestinal activity.
3. Monitor bowel sounds and for abdominal tenderness and cramping.
4. Monitor stools, noting color, consistency, and the presence or absence of blood.
5. Monitor for bowel perforation, peritonitis (see Box 48-3), and hemorrhage.
6. Following the acute phase, the diet progresses from clear liquids to a low-fiber diet as tolerated.
7. Instruct the client about diet. Usually a low-fiber diet
is prescribed during an exacerbation episode; in addition, a high-protein diet with vitamins and iron supplements are prescribed.
8. Instruct the client to avoid gas-forming foods, milk products, and foods such as whole-wheat grains, nuts, raw fruits and vegetables, pepper, alcohol, and caffeine-containing products.
9. Instruct the client to avoid smoking.
10. Administer medications as prescribed, which may include a combination of medications such as salicylate compounds, corticosteroids, immunosuppressants, and antidiarrheals.

D. Surgical interventions
1. Performed in extreme cases if medical management is unsuccessful
2. Minimally invasive procedures are considered as a surgical option if the client is a candidate; clients who are obese, have had previous abdominal surgeries, or have adhesions may not be candidates.
3. Minimally invasive procedures can include laparoscopic procedures, robotic-assisted surgery, and natural orifice transluminal endoscopic surgery (NOTES).
4. Restorative proctocolectomy with ileal pouch–anal anastomosis (RPC-IPAA)
   a. Allows for bowel continence
   b. May be performed through laparoscopic procedure
   c. Involves a 2-stage procedure that includes removal of the colon and most of the rectum; the anus and anal sphincter remain intact.
   d. An internal pouch known as a reservoir (J-pouch, S-pouch, or pelvic pouch) is created using the small intestine and connected to the anus, followed by creation of a temporary ileostomy through the abdominal skin to allow healing of the internal pouch and all anastomosis sites.
   e. In the second surgical procedure (within 1 to 2 months), the ileostomy is closed.
5. Total proctocolectomy with permanent ileostomy
   a. Performed if the client is not a candidate for RPC-IPAA or if the client prefers this type of procedure.
   b. The procedure involves the removal of
the entire colon (colon, rectum, and anus, with anal closure).
c. The end of the terminal ileum forms the stoma or ostomy, which is located in the right lower quadrant.

6. Preoperative interventions
   a. Consult with the enterostomal therapist to help identify optimal placement of the ostomy.
   b. Instruct the client on dietary restrictions; the client may need to follow a low-fiber diet for 1 to 2 days before surgery.
   c. Parenteral antibiotics are administered 1 hour before the surgical opening.
   d. Address body image concerns and allow the client to express concerns; a visit from an ostomate may be helpful to the client.

7. Postoperative interventions
   a. A pouch system with a skin barrier is usually placed on the stoma postoperatively; if a pouch system is not covering the stoma, a petrolatum gauze dressing is placed over the stoma as prescribed to keep it moist, followed by a dry sterile dressing.
   b. Monitor the stoma for size, unusual bleeding, or necrotic tissue.
   c. Monitor for color changes in the stoma.
   d. Note that the normal stoma color is pink to bright red and shiny, indicating high vascularity.
   e. Note that a pale pink stoma indicates low hemoglobin and hematocrit levels and a purple-black stoma indicates compromised circulation, requiring PHCP notification.
   f. Assess the functioning of the ostomy.
   g. Expect that stool is liquid in the immediate postoperative period but
becomes more solid depending on the area of creation—ascending colon, liquid; transverse colon, loose to semifomed; and descending colon, close to normal.

h. Monitor the pouch system for proper fit and signs of leakage; the pouch is emptied when it is one-third full.
i. Fecal matter should not be allowed to remain on the skin; skin assessment and care are a priority.
j. Monitor for dehydration and electrolyte imbalance.
k. Administer analgesics and antibiotics as prescribed.
l. Instruct the client to avoid foods that cause excess gas formation and odor.
m. Instruct the client about stoma care and irrigations if prescribed (Box 48-11).
n. Instruct the client that normal activities may be resumed when approved by the PHCP.

XXVI. Crohn’s Disease
A. Description
1. An inflammatory disease that can occur anywhere in the gastrointestinal tract but most often affects the terminal ileum and leads to thickening and scarring, a narrowed lumen, fistulas, ulcerations, and abscesses
2. Characterized by remissions and exacerbations
B. Assessment
1. Fever
2. Cramp-like and colicky pain after meals
3. Diarrhea (semisolid), which may contain mucus and pus
4. Abdominal distention
5. Anorexia, nausea, and vomiting
6. Weight loss
7. Anemia
8. Dehydration
9. Electrolyte imbalances

10. Malnutrition (may be worse than that seen in ulcerative colitis)

C. Interventions: Care is similar to that for the client with ulcerative colitis; however, surgery may be necessary but is avoided for as long as possible because recurrence of the disease process in the same region is likely to occur.

XXVII. Appendicitis

A. Description
   1. Inflammation of the appendix
   2. When the appendix becomes inflamed or infected, rupture may occur within a matter of hours, leading to peritonitis and sepsis.

B. Assessment
   1. Pain in the periumbilical area that descends to the right lower quadrant
   2. Abdominal pain that is most intense at McBurney’s point
   3. Rebound tenderness and abdominal rigidity
   4. Low-grade fever
   5. Elevated white blood cell count
   6. Anorexia, nausea, and vomiting
   7. Client in side-lying position, with abdominal guarding and legs flexed
   8. Constipation or diarrhea

C. Peritonitis: Inflammation of the peritoneum (see Box 48-3)

D. Appendectomy: Surgical removal of the appendix

   1. Preoperative interventions
      a. Maintain NPO status.
      b. Administer fluids intravenously to prevent dehydration.
      c. Monitor for changes in level of pain.
      d. Monitor for signs of ruptured appendix and peritonitis (see Box 48-3).
      e. Position the client in a right side-lying or low to semi-Fowler’s position to promote comfort.
      f. Monitor bowel sounds.
      g. Apply ice packs to the abdomen for 20 to 30 minutes every hour if prescribed.
      h. Administer antibiotics as prescribed.
i. Avoid laxatives or enemas.

Avoid the application of heat to the abdomen of a client with appendicitis. Heat can cause rupture of the appendix leading to peritonitis, a life-threatening condition.

2. Postoperative interventions
a. Monitor temperature for signs of infection.
b. Assess incision for signs of infection such as redness, swelling, and pain.
c. Maintain NPO status until bowel function has returned.
d. Advance diet gradually as tolerated and as prescribed, when bowel sounds return.
e. If rupture of the appendix occurred, expect a drain to be inserted, or the incision may be left open to heal from the inside out.
f. Expect that drainage from the drain may be profuse for the first 12 hours.
g. Position the client in a right side-lying or low to semi-Fowler’s position, with legs flexed, to facilitate drainage.
h. Change the dressing as prescribed and record the type and amount of drainage.
i. Perform wound irrigations if prescribed.
j. Maintain NG suction and patency of the NG tube if present.
k. Administer antibiotics and analgesics as prescribed.

XXVIII. Diverticulosis and Diverticulitis
A. Description
1. Diverticulosis
a. **Diverticulosis** is an outpouching or herniation of the intestinal mucosa.
b. The disorder can occur in any part of the intestine but is most common in the sigmoid colon.

2. Diverticulitis
a. **Diverticulitis** is the inflammation of 1
or more diverticula that occurs from penetration of fecal matter through the thin-walled diverticula; it can result in local abscess formation and perforation.

b. A perforated diverticulum can progress to intra-abdominal perforation with generalized peritonitis.

B. Assessment

1. Left lower quadrant abdominal pain that increases with coughing, straining, or lifting
2. Elevated temperature
3. Nausea and vomiting
4. Flatulence
5. Cramp-like pain
6. Abdominal distention and tenderness
7. Palpable, tender rectal mass may be present.
8. Blood in the stools

C. Interventions

1. Provide bed rest during the acute phase.
2. Maintain NPO status or provide clear liquids during the acute phase as prescribed.
3. Introduce a fiber-containing diet gradually, when the inflammation has resolved.
4. Administer antibiotics, analgesics, and anticholinergics to reduce bowel spasms as prescribed.
5. Instruct the client to refrain from lifting, straining, coughing, or bending to avoid increased intra-abdominal pressure.
6. Monitor for perforation (see Box 48-3), hemorrhage, fistulas, and abscesses.
7. Instruct the client to increase fluid intake to 2500 to 3000 mL daily, unless contraindicated.
8. Instruct the client to eat soft high-fiber foods, such as whole grains; the client should avoid high-fiber foods when inflammation occurs, because these foods will irritate the mucosa further.
9. Instruct the client to avoid gas-forming foods or foods containing indigestible roughage, seeds, nuts, or popcorn, because these food substances become trapped in diverticula and cause inflammation.
10. Instruct the client to consume a small amount of bran daily and to take bulk-forming laxatives as prescribed.
to increase stool mass.

D. Surgical interventions
1. Colon resection with primary anastomosis may be an option.
2. Temporary or permanent colostomy may be required for increased bowel inflammation.

XXIX. Hemorrhoids
A. Description
1. Dilated varicose veins of the anal canal
2. May be internal, external, or prolapsed
3. Internal hemorrhoids lie above the anal sphincter and cannot be seen on inspection of the perianal area.
4. External hemorrhoids lie below the anal sphincter and can be seen on inspection.
5. Prolapsed hemorrhoids can become thrombosed or inflamed.
6. Hemorrhoids are caused from portal hypertension, straining, irritation, or increased venous or abdominal pressure.

B. Assessment
1. Bright red bleeding with defecation
2. Rectal pain
3. Rectal itching

C. Interventions
1. Apply cold packs to the anal-rectal area followed by sitz baths as prescribed.
2. Apply witch hazel soaks and topical anesthetics as prescribed.
3. Encourage a high-fiber diet and fluids to promote bowel movements without straining.
4. Administer stool softeners as prescribed.

D. Surgical interventions: May include ultrasound, sclerotherapy, circular stapling, band ligation, or simple resection of the hemorrhoids (hemorrhoidectomy)

E. Postoperative interventions following hemorrhoidectomy
1. Assist the client to a prone or side-lying position to prevent bleeding.
2. Maintain ice packs over the dressing as prescribed until the packing is removed by the PHCP.
4. Administer stool softeners as prescribed.
5. Instruct the client to increase fluids and high-fiber foods.
6. Instruct the client to limit sitting to short periods of time.
7. Instruct the client in the use of sitz baths three or four times a day as prescribed.

**Box 48-1**

**Risk Factors Associated with the Gastrointestinal System**

- Allergic reactions to food or medications
- Cardiac, respiratory, and endocrine disorders that may lead to slowed gastrointestinal (GI) movement or constipation
- Chronic alcohol use
- Chronic high stress levels
- Chronic laxative use
- Chronic use of aspirin or nonsteroidal antiinflammatory drugs (NSAIDs)
- Diabetes mellitus, which may predispose to oral candidal infections or other GI disorders
- Family history of GI disorders
- Long-term GI conditions, such as ulcerative colitis, that may predispose to colorectal cancer
- Neurological disorders that can impair movement, particularly with chewing and swallowing
- Previous abdominal surgery or trauma, which may lead to adhesions
- Tobacco use

**Box 48-2**

**Common Gastrointestinal System Diagnostic Studies**

- Capsule endoscopy
- Endoscopic retrograde cholangiopancreatography (ERCP)
- Magnetic resonance cholangiopancreatography (MRCP)
- Endoscopic ultrasound
- Fiberoptic colonoscopy
- Gastric analysis
- Gastrointestinal motility studies
- Hydrogen and urea breath test
- Laparoscopy: Liver and pancreas laboratory studies
- Liver biopsy
- Paracentesis
- Stool specimens
- Upper gastrointestinal endoscopy or esophagogastrroduodenoscopy
- Upper gastrointestinal tract study (barium swallow)
- Videofluoroscopic swallowing study
- Informed consent is obtained for a diagnostic study that is invasive.

**Box 48-3**

**Signs of Bowel Perforation and Peritonitis**

- Guarding of the abdomen
- Increased temperature and chills
- Pallor
- Progressive abdominal distention and abdominal pain
- Restlessness
- Tachycardia and tachypnea

**Box 48-4**

**Assessment Findings in Acute and Chronic Gastritis**

**Acute**

- Abdominal discomfort
- Anorexia, nausea, and vomiting
- Headache
- Hiccupping
- Reflux

**Chronic**

- Anorexia, nausea, and vomiting
- Belching
- Heartburn after eating
- Sour taste in the mouth
- Vitamin B₁₂ deficiency
Box 48-5

Assessment: Gastric and Duodenal Ulcers

Gastric

- Gnawing, sharp pain in or to the left of the midepigastric region occurs 30 to 60 minutes after a meal (food ingestion accentuates the pain).
- Hematemesis is more common than melena.

Duodenal

- Burning pain occurs in the midepigastric area 1.5 to 3 hours after a meal and during the night (often awakens the client).
- Melena is more common than hematemesis.
- Pain is often relieved by the ingestion of food.
FIG. 48-1 The Billroth I procedure (gastroduodenostomy). The distal portion of the stomach is removed, and the remainder is anastomosed to the duodenum.
FIG. 48-2 The Billroth II procedure (gastrojejunostomy). The lower portion of the stomach is removed, and the remainder is anastomosed to the jejunum.

Box 48-6

Client Education: Preventing Dumping Syndrome

- Avoid sugar, salt, and milk.
- Eat a high-protein, high-fat, low-carbohydrate diet.
- Eat small meals and avoid consuming fluids with meals.
- Lie down after meals.
- Take antispasmodic medications as prescribed to delay gastric emptying.
FIG. 48-3 Bariatric surgical procedures.

Box 48-7
Dietary Measures for the Client Following Bariatric Surgery

- Avoid alcohol, high-protein foods, and foods high in sugar and fat.
- Eat slowly and chew food well.
- Progress food types and amounts as prescribed.
- Take nutritional supplements as prescribed, which may include calcium, iron, multivitamins, and vitamin B₁₂.
- Monitor and report signs and symptoms of complications, such as dehydration and gastric leak (persistent abdominal pain, nausea, vomiting).

Box 48-8
Care of a T-Tube

Purpose and Description
A T-tube is placed after surgical exploration of the common bile duct. The tube preserves the patency of the duct and ensures drainage of bile until edema resolves and bile is effectively draining into the duodenum. A gravity drainage bag is attached to the T-tube to collect the drainage.

**Interventions**

- Place the client in semi-Fowler’s position to facilitate drainage.
- Monitor the output amount and the color, consistency, and odor of the drainage.
- Report sudden increases in bile output to the primary health care provider (PHCP).
- Monitor for inflammation and protect the skin from irritation.
- Keep the drainage system below the level of the gallbladder.
- Monitor for foul odor and purulent drainage and report its presence to the PHCP.
- Avoid irrigation, aspiration, or clamping of the T-tube without a PHCP’s prescription.
- As prescribed, clamp the tube before a meal and observe for abdominal discomfort and distention, nausea, chills, or fever; unclamp the tube if nausea or vomiting occurs.

**FIG. 48-4** Clinical picture of a client with liver dysfunction. Manifestations vary according to the progression of the disease. Some dermatological manifestations are noted in color (and marked with asterisks).
FIG. 48-5 How to measure abdominal girth. With the client supine, bring the tape measure around the client and take a measurement at the level of the umbilicus. Before removing the tape, mark the client’s abdomen along the sides of tape on the client’s flanks (sides) and midline to ensure that later measurements are taken at the same place.
**FIG. 48-6** Eliciting asterixis (flapping tremor). Have the client extend the arm, dorsiflex the wrist, and extend the fingers. Observe for rapid, nonrhythmic extensions and flexions.

**FIG. 48-7** Surgical shunting diverts portal venous blood flow from the liver to decrease portal and esophageal pressure.

---

**Box 48-9**

**Stages and Assessment of Viral Hepatitis**

**Preicteric Stage**

The first stage of hepatitis, preceding the appearance of jaundice; includes flu-like symptoms—malaise, fatigue; anorexia, nausea, vomiting, diarrhea; pain—headache, muscle aches, polyarthritis; and elevated serum bilirubin and enzyme levels.
Icteric Stage
The second stage of hepatitis; includes the appearance of jaundice and associated symptoms such as elevated bilirubin levels, dark or tea-colored urine, and clay-colored stools; pruritus; and a decrease in preicteric-phase symptoms.

Posticteric Stage
The convalescent stage of hepatitis, in which the jaundice decreases and the color of the urine and stool returns to normal; energy increases, pain subsides, there is minimal to absent gastrointestinal symptoms, and bilirubin and enzyme levels return to normal.

Box 48-10
Home Care Instructions for the Client with Hepatitis

- Hand washing must be strict and frequent.
- Do not share bathrooms unless the client strictly adheres to personal hygiene measures.
- Individual washcloths, towels, drinking and eating utensils, and toothbrushes and razors must be labeled and used only by the client.
- The client must not prepare food for other family members.
- The client should avoid alcohol and over-the-counter medications, particularly acetaminophen and sedatives, because these medications are hepatotoxic.
- The client should increase activity gradually to prevent fatigue.
- The client should consume small, frequent meals consisting of high-carbohydrate, low-fat foods.
- The client is not to donate blood.
- The client may maintain normal contact with persons as long as proper personal hygiene is maintained.
- Close personal contact such as kissing and sexual activity should be discouraged with hepatitis B until surface antigen test results are negative.
- The client needs to carry a MedicAlert card noting the date of hepatitis onset.
- The client needs to inform other health professionals, such as medical or dental personnel, of the onset of hepatitis.
- The client needs to keep follow-up appointments with the primary health care provider.

Box 48-11
Colostomy Irrigation

Purpose
An enema is given through the stoma to stimulate bowel emptying.

**Description**

Irrigation is performed by instilling 500 to 1000 mL of lukewarm tap water through the stoma and allowing the water and stool to drain into a collection bag.

**Procedure**

- If ambulatory, position the client sitting on the toilet.
- If on bed rest, position the client on her or his side.
- Hang the irrigation bag so that the bottom of the bag is at the level of the client’s shoulder or slightly higher.
- Insert the irrigation tube carefully without force.
- Begin the flow of irrigation.
- Clamp the tubing if cramping occurs; release the tubing as cramping subsides.
- Avoid frequent irrigations, which can lead to loss of fluids and electrolytes.
- Perform irrigation at about the same time each day.
- Perform irrigation preferably 1 hour after a meal.
- To enhance effectiveness of the irrigation, massage the abdomen gently.

**Practice Questions**

529. The nurse is monitoring a client admitted to the hospital with a diagnosis of appendicitis who is scheduled for surgery in 2 hours. The client begins to complain of increased abdominal pain and begins to vomit. On assessment, the nurse notes that the abdomen is distended and bowel sounds are diminished. Which is the most appropriate nursing intervention?

1. Administer the prescribed pain medication.
2. Notify the primary health care provider (PHCP).
3. Call and ask the operating room team to perform surgery as soon as possible.
4. Reposition the client and apply a heating pad on the warm setting to the client’s abdomen.

530. A client admitted to the hospital with a suspected diagnosis of acute pancreatitis is being assessed by the nurse. Which assessment findings would be consistent with acute pancreatitis? Select all that apply.

- [ ] 1. Diarrhea
- [ ] 2. Black, tarry stools
- [ ] 3. Hyperactive bowel sounds
- [ ] 4. Gray-blue color at the flank
- [ ] 5. Abdominal guarding and tenderness
- [ ] 6. Left upper quadrant pain with radiation to the back
531. The nurse is assessing a client who is experiencing an acute episode of cholecystitis. Which of these clinical manifestations support this diagnosis? Select all that apply.

1. Fever
2. Positive Cullen’s sign
3. Complaints of indigestion
4. Palpable mass in the left upper quadrant
5. Pain in the upper right quadrant after a fatty meal
6. Vague lower right quadrant abdominal discomfort

532. A client is diagnosed with viral hepatitis, complaining of “no appetite” and “losing my taste for food.” What instruction should the nurse give the client to provide adequate nutrition?

1. Select foods high in fat.
2. Increase intake of fluids, including juices.
3. Eat a good supper when anorexia is not as severe.
4. Eat less often, preferably only 3 large meals daily.

533. A client has developed hepatitis A after eating contaminated oysters. The nurse assesses the client for which expected assessment finding?

1. Malaise
2. Dark stools
3. Weight gain
4. Left upper quadrant discomfort

534. A client has just had a hemorrhoidectomy. Which nursing interventions are appropriate for this client? Select all that apply.

1. Administer stool softeners as prescribed.
2. Instruct the client to limit fluid intake to avoid urinary retention.
3. Encourage a high-fiber diet to promote bowel movements without straining.
4. Apply cold packs to the anal-rectal area over the dressing until the packing is removed.
5. Help the client to a Fowler’s position to place pressure on the rectal area and decrease bleeding.

535. The nurse is planning to teach a client with gastroesophageal reflux disease (GERD) about substances to avoid. Which items should the nurse include on this list? Select all that apply.

1. Coffee
2. Chocolate
3. Peppermint
4. Nonfat milk
☐ 5. Fried chicken
☐ 6. Scrambled eggs

536. A client has undergone esophagogastroduodenoscopy. The nurse should place **highest priority** on which item as part of the client’s care plan?
1. Monitoring the temperature
2. Monitoring complaints of heartburn
3. Giving warm gargles for a sore throat
4. Assessing for the return of the gag reflex

537. The nurse has taught the client about an upcoming endoscopic retrograde cholangiopancreatography (ERCP) procedure. The nurse determines that the client **needs further information** if the client makes which statement?
1. “I know I must sign the consent form.”
2. “I hope the throat spray keeps me from gagging.”
3. “I’m glad I don’t have to lie still for this procedure.”
4. “I’m glad some intravenous medication will be given to relax me.”

538. The primary health care provider has determined that a client has contracted hepatitis A based on flu-like symptoms and jaundice. Which statement made by the client supports this medical diagnosis?
1. “I have had unprotected sex with multiple partners.”
2. “I ate shellfish about 2 weeks ago at a local restaurant.”
3. “I was an intravenous drug abuser in the past and shared needles.”
4. “I had a blood transfusion 30 years ago after major abdominal surgery.”

539. The nurse is assessing a client 24 hours following a cholecystectomy. The nurse notes that the T-tube has drained 750 mL of green-brown drainage since the surgery. Which nursing intervention is **most appropriate**?
1. Clamp the T-tube.
2. Irrigate the T-tube.
3. Document the findings.
4. Notify the primary health care provider.

540. The nurse is monitoring a client with a diagnosis of peptic ulcer. Which assessment finding would **most likely** indicate perforation of the ulcer?
1. Bradycardia
2. Numbness in the legs
3. Nausea and vomiting
4. A rigid, board-like abdomen

541. The nurse is caring for a client following a gastrojejunostomy (Billroth II procedure). Which postoperative prescription should the nurse question and verify?
1. Leg exercises
2. Early ambulation
3. Irrigating the nasogastric tube
4. Coughing and deep-breathing exercises

542. The nurse is providing discharge instructions to a client following
gastrectomy and should instruct the client to take which measure to assist in preventing dumping syndrome?
1. Ambulate following a meal.
2. Eat high-carbohydrate foods.
3. Limit the fluids taken with meals.
4. Sit in a high-Fowler’s position during meals.

543. The nurse is reviewing the prescription for a client admitted to the hospital with a diagnosis of acute pancreatitis. Which interventions would the nurse expect to be prescribed for the client? **Select all that apply.**

- [ ] 1. Maintain NPO (nothing by mouth) status.
- [ ] 2. Encourage coughing and deep breathing.
- [ ] 3. Give small, frequent high-calorie feedings.
- [ ] 4. Maintain the client in a supine and flat position.
- [ ] 5. Give hydromorphone intravenously as prescribed for pain.
- [ ] 6. Maintain intravenous fluids at 10 mL/hr to keep the vein open.

544. The nurse is providing discharge teaching for a client with newly diagnosed Crohn’s disease about dietary measures to implement during exacerbation episodes. Which statement made by the client indicates a need for further instruction?

1. “I should increase the fiber in my diet.”
2. “I will need to avoid caffeinated beverages.”
3. “I’m going to learn some stress reduction techniques.”
4. “I can have exacerbations and remissions with Crohn’s disease.”

545. The nurse is reviewing the record of a client with a diagnosis of cirrhosis and notes that there is documentation of the presence of asterixis. How should the nurse assess for its presence?

1. Dorsiflex the client’s foot.
2. Measure the abdominal girth.
3. Ask the client to extend the arms.
4. Instruct the client to lean forward.

546. The nurse is reviewing the laboratory results for a client with cirrhosis and notes that the ammonia level is 85 mcg/dL (51 mcmol/L). Which dietary selection does the nurse suggest to the client?

1. Roast pork
2. Cheese omelet
3. Pasta with sauce
4. Tuna fish sandwich

547. The nurse is doing an admission assessment on a client with a history of duodenal ulcer. To determine whether the problem is currently active, the nurse should assess the client for which manifestation of duodenal ulcer?
1. Weight loss
2. Nausea and vomiting
3. Pain relieved by food intake
4. Pain radiating down the right arm

548. A client with hiatal hernia chronically experiences heartburn following meals. The nurse should plan to teach the client to avoid which action because it is contraindicated with a hiatal hernia?
   1. Lying recumbent following meals
   2. Consuming small, frequent, bland meals
   3. Taking H₂-receptor antagonist medication
   4. Raising the head of the bed on 6-inch (15 cm) blocks

549. The nurse is providing care for a client with a recent transverse colostomy. Which observation requires immediate notification of the primary health care provider?
   1. Stoma is beefy red and shiny
   2. Purple discoloration of the stoma
   3. Skin excoriation around the stoma
   4. Semiformed stool noted in the ostomy pouch

550. A client had a new colostomy created 2 days earlier and is beginning to pass malodorous flatus from the stoma. What is the correct interpretation by the nurse?
   1. This is a normal, expected event.
   2. The client is experiencing early signs of ischemic bowel.
   3. The client should not have the nasogastric tube removed.
   4. This indicates inadequate preoperative bowel preparation.

551. A client has just had surgery to create an ileostomy. The nurse assesses the client in the immediate postoperative period for which most frequent complication of this type of surgery?
   1. Folate deficiency
   2. Malabsorption of fat
   3. Intestinal obstruction
   4. Fluid and electrolyte imbalance

552. The nurse provides instructions to a client about measures to treat inflammatory bowel syndrome (IBS). Which statement by the client indicates a need for further teaching?
   1. “I need to limit my intake of dietary fiber.”
   2. “I need to drink plenty, at least 8 to 10 cups daily.”
   3. “I need to eat regular meals and chew my food well.”
   4. “I will take the prescribed medications because they will regulate my bowel patterns.”

553. The nurse is monitoring a client for the early signs and symptoms of dumping syndrome. Which findings indicate this occurrence?
   1. Sweating and pallor
   2. Bradycardia and indigestion
   3. Double vision and chest pain
   4. Abdominal cramping and pain

Answers

529. Answer: 2
**Rationale:** On the basis of the signs and symptoms presented in the question, the nurse should suspect peritonitis and notify the PHCP. Administering pain medication is not an appropriate intervention. Heat should never be applied to the abdomen of a client with suspected appendicitis because of the risk of rupture. Scheduling surgical time is not within the scope of nursing practice, although the PHCP probably would perform the surgery earlier than the prescheduled time.

**Test-Taking Strategy:** Note the strategic words, most appropriate. Determine if an abnormality exists, focus on the signs and symptoms in the question, and consider the complications that can occur with appendicitis. Noting that the signs presented in the question indicate a complication will assist in directing you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Adult Health: Gastrointestinal

**Health Problem:** Adult Health: Gastrointestinal: GI Accessory Organs

**Priority Concepts:** Clinical Judgment; Inflammation

530. **Answer:** 4, 5, 6

**Rationale:** Grayish-blue discoloration at the flank is known as Grey-Turner’s sign and occurs as a result of pancreatic enzyme leakage to cutaneous tissue from the peritoneal cavity. The client may demonstrate abdominal guarding and may complain of tenderness with palpation. The pain associated with acute pancreatitis is often sudden in onset and is located in the epigastric region or left upper quadrant with radiation to the back. The other options are incorrect.

**Test-Taking Strategy:** Noting that options 1 and 3 are comparable or alike will assist you in eliminating these options first. Then recall that black, tarry stools occur when there is gastrointestinal bleeding, so this can also be eliminated. From the remaining options, recall the anatomical location of the pancreas, the pain characteristics, and the effect of enzymes leaking into the tissues to direct you to the correct options.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Gastrointestinal

**Health Problem:** Adult Health: Gastrointestinal: GI Accessory Organs

**Priority Concepts:** Inflammation; Pain

531. **Answer:** 1, 3, 5

**Rationale:** During an acute episode of cholecystitis, the client may complain of severe right upper quadrant pain that radiates to the right scapula or shoulder or experience epigastric pain after a fatty or high-volume meal. Fever and signs of dehydration would also be expected, as well as complaints of indigestion, belching,
flatulence, nausea, and vomiting. Options 4 and 6 are incorrect because they are inconsistent with the anatomical location of the gallbladder. Option 2 (Cullen’s sign) is associated with pancreatitis.

**Test-Taking Strategy:** Focus on the **subject**, the location and characteristics of pain associated with cholecystitis. Recalling the anatomical location of the gallbladder will also direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Gastrointestinal

**Health Problem:** Adult Health: Gastrointestinal: GI Accessory Organs

**Priority Concepts:** Inflammation; Pain

532. **Answer:** 2

**Rationale:** Although no special diet is required to treat viral hepatitis, it is generally recommended that clients consume a low-fat diet, as fat may be tolerated poorly because of decreased bile production. Small, frequent meals are preferable and may even prevent nausea. Frequently, appetite is better in the morning, so it is easier to eat a good breakfast. An adequate fluid intake of 2500 to 3000 mL/day that includes nutritional juices is also important.

**Test-Taking Strategy:** Focus on the **subject**, a diet for viral hepatitis. Think about the pathophysiology associated with hepatitis and focus on the client’s complaints to direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Adult Health: Gastrointestinal

**Health Problem:** Adult Health: Gastrointestinal: GI Accessory Organs

**Priority Concepts:** Client Education; Infection

533. **Answer:** 1

**Rationale:** Hepatitis causes gastrointestinal symptoms such as anorexia, nausea, right upper quadrant discomfort, and weight loss. Fatigue and malaise are common. Stools will be light- or clay-colored if conjugated bilirubin is unable to flow out of the liver because of inflammation or obstruction of the bile ducts.

**Test-Taking Strategy:** Focus on the **subject**, expected assessment findings. Recalling the function of the liver will direct you to the correct option. Remember that fatigue and malaise are common.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Gastrointestinal

**Health Problem:** Adult Health: Gastrointestinal: GI Accessory Organs
Priority Concepts: Clinical Judgment; Infection

534. Answer: 1, 3, 4

Rationale: Nursing interventions after a hemorrhoidectomy are aimed at management of pain and avoidance of bleeding and incision rupture. Stool softeners and a high-fiber diet will help the client avoid straining, thereby reducing the chances of rupturing the incision. An ice pack will increase comfort and decrease bleeding. Options 2 and 5 are incorrect interventions.

Test-Taking Strategy: Focus on the subject, postoperative hemorrhoidectomy care. Recall that decreasing fluid intake will cause difficulty with defecation because of hard stool. Recognize that Fowler’s position will increase pressure in the rectal area, causing increased bleeding and increased pain.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: Lower GI Disorders
Priority Concepts: Elimination; Pain

535. Answer: 1, 2, 3, 5

Rationale: Foods that decrease lower esophageal sphincter (LES) pressure and irritate the esophagus will increase reflux and exacerbate the symptoms of GERD and therefore should be avoided. Aggravating substances include coffee, chocolate, peppermint, fried or fatty foods, carbonated beverages, and alcohol. Options 4 and 6 do not promote this effect.

Test-Taking Strategy: Focus on the subject, food items to avoid. Use knowledge of the effect of various foods on LES pressure and GERD. However, if you are unsure, note that options 4 and 6 are the most healthful food items.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: Upper GI Disorders
Priority Concepts: Client Education; Inflammation

536. Answer: 4

Rationale: The nurse places highest priority on assessing for return of the gag reflex. This assessment addresses the client’s airway. The nurse also monitors the client’s vital signs and for a sudden increase in temperature, which could indicate perforation of the gastrointestinal tract. This complication would be accompanied by other signs as well, such as pain. Monitoring for sore throat and heartburn are also
important; however, the client’s airway is the priority.

Test-Taking Strategy: Note the strategic words, highest priority. Use the ABCs—airway, breathing, and circulation. The correct option addresses the airway.

Level of Cognitive Ability: Analyzing
Client Needs: Safe and Effective Care Environment
Integrated Process: Nursing Process—Planning
Content Area: Foundations of Care: Diagnostic Tests
Health Problem: N/A
Priority Concepts: Clinical Judgment; Safety

537. Answer: 3

Rationale: The client does have to lie still for ERCP, which takes about 1 hour to perform. The client also has to sign a consent form. Intravenous sedation is given to relax the client, and an anesthetic spray is used to help keep the client from gagging as the endoscope is passed.

Test-Taking Strategy: Note the strategic words, needs further information. These words indicate a negative event query and ask you to select an option that is incorrect. Invasive procedures require consent, so option 1 can be eliminated. Noting the name of the procedure and considering the anatomical location will assist you in eliminating options 2 and 4.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Foundations of Care: Diagnostic Tests
Health Problem: N/A
Priority Concepts: Client Education; Safety

538. Answer: 2

Rationale: Hepatitis A is transmitted by the fecal-oral route via contaminated water or food (improperly cooked shellfish), or infected food handlers. Hepatitis B, C, and D are transmitted most commonly via infected blood or body fluids, such as in the cases of intravenous drug abuse, history of blood transfusion, or unprotected sex with multiple partners.

Test-Taking Strategy: Focus on the subject, hepatitis A. Recalling the modes of transmission of the various types of hepatitis is required to answer this question. Remember that hepatitis A is transmitted by the fecal-oral route.

Level of Cognitive Ability: Analyzing
Client Needs: Safe and Effective Care Environment
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: GI Accessory Organs
Priority Concepts: Infection; Inflammation
539. **Answer:** 3

**Rationale:** Following cholecystectomy, drainage from the T-tube is initially bloody and then turns a greenish-brown color. The drainage is measured as output. The amount of expected drainage will range from 500 to 1000 mL/day. The nurse would document the output.

**Test-Taking Strategy:** Note the **strategic words, most appropriate.** Options 1 and 2 can be eliminated because a T-tube is not irrigated and would not be clamped with this amount of drainage. From the remaining options, you must know normal expected findings following this surgical procedure.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Adult Health: Gastrointestinal

**Health Problem:** Adult Health: Gastrointestinal: GI Accessory Organs

**Priority Concepts:** Clinical Judgment; Elimination

**Reference:** Lewis et al. (2017), pp. 344, 1009.

540. **Answer:** 4

**Rationale:** Perforation of an ulcer is a surgical emergency and is characterized by sudden, sharp, intolerable severe pain beginning in the midepigastric area and spreading over the abdomen, which becomes rigid and boardlike. Nausea and vomiting may occur. Tachycardia may occur as hypovolemic shock develops. Numbness in the legs is not an associated finding.

**Test-Taking Strategy:** Focus on the **subject,** perforation. Option 2 can be eliminated easily because it is not related to perforation. Eliminate option 1 next because tachycardia rather than bradycardia would develop if perforation occurs. From the remaining options, note the **strategic words, most likely,** to help direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Gastrointestinal

**Health Problem:** Adult Health: Gastrointestinal: Upper GI Disorders

**Priority Concepts:** Clinical Judgment; Safety

541. **Answer:** 3

**Rationale:** In a gastrojejunostomy (Billroth II procedure), the proximal remnant of the stomach is anastomosed to the proximal jejunum. Patency of the nasogastric tube is critical for preventing the retention of gastric secretions. The nurse should never irrigate or reposition the gastric tube after gastric surgery, unless specifically prescribed by the primary health care provider. In this situation, the nurse should clarify the prescription. Options 1, 2, and 4 are appropriate postoperative interventions.
Test-Taking Strategy: Note the words question and verify. Eliminate options 1, 2, and 4 because they are comparable or alike and are general postoperative measures. Also, consider the anatomical location of the surgical procedure to assist in directing you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Analysis
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: Upper GI Disorders
Priority Concepts: Clinical Judgment; Safety

542. Answer: 3

Rationale: Dumping syndrome is a term that refers to a constellation of vasomotor symptoms that occurs after eating, especially following a gastrojejunostomy (Billroth II procedure). Early manifestations usually occur within 30 minutes of eating and include vertigo, tachycardia, syncope, sweating, pallor, palpitations, and the desire to lie down. The nurse should instruct the client to decrease the amount of fluid taken at meals and to avoid high-carbohydrate foods, including fluids such as fruit nectars; to assume a low-Fowler’s position during meals; to lie down for 30 minutes after eating to delay gastric emptying; and to take antispasmodics as prescribed.

Test-Taking Strategy: Eliminate options 1 and 4 first because these measures are comparable or alike and will promote gastric emptying. From the remaining options, select the measure that will delay gastric emptying.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: Upper GI Disorders
Priority Concepts: Client Education; Nutrition
Reference: Lewis et al. (2017), pp. 917-918.

543. Answer: 1, 2, 5

Rationale: The client with acute pancreatitis normally is placed on NPO status to rest the pancreas and suppress gastrointestinal secretions, so adequate intravenous hydration is necessary. Because abdominal pain is a prominent symptom of pancreatitis, pain medications such as morphine or hydromorphone are prescribed. Meperidine is avoided, as it may cause seizures. Some clients experience lessened pain by assuming positions that flex the trunk, with the knees drawn up to the chest. A side-lying position with the head elevated 45 degrees decreases tension on the abdomen and may help ease the pain. The client is susceptible to respiratory infections because the retroperitoneal fluid raises the diaphragm, which causes the client to take shallow, guarded abdominal breaths. Therefore, measures such as turning, coughing, and deep breathing are instituted.

Test-Taking Strategy: Focus on the subject, care for the client with acute
pancreatitis. Think about the pathophysiology associated with pancreatitis and note the word *acute*. This will assist in selecting the correct options.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity

**Health Problem:** Adult Health: Gastrointestinal: GI Accessory Organs  
**Priority Concepts:** Pain; Inflammation  
**Reference:** Lewis et al. (2017), pp. 1001-1002.

544. **Answer:** 1

**Rationale:** Crohn’s disease is an inflammatory disease that can occur anywhere in the gastrointestinal tract but most often affects the terminal ileum and leads to thickening and scarring, a narrowed lumen, fistulas, ulcerations, and abscesses. It is characterized by exacerbations and remissions. If stress increases the symptoms of the disease, the client is taught stress management techniques and may require additional counseling. The client is taught to avoid gastrointestinal stimulants containing caffeine and to follow a high-calorie and high-protein diet. A low-fiber diet may be prescribed, especially during periods of exacerbation.

**Test-Taking Strategy:** Note the strategic words, *need for further instruction*. These words indicate a negative event query and ask you to select an option that is incorrect. Also, focus on the information in the question and that the question addresses exacerbation. Knowing that the client should consume a diet high in protein and calories and low in fiber will direct you to option 1. Options 2, 3, and 4 are correct statements.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Gastrointestinal  
**Health Problem:** Adult Health: Gastrointestinal: Lower GI Disorders  
**Priority Concepts:** Client Education; Elimination  
**Reference:** Lewis et al. (2017), pp. 945-946.

545. **Answer:** 3

**Rationale:** Asterixis is irregular flapping movements of the fingers and wrists when the hands and arms are outstretched, with the palms down, wrists bent up, and fingers spread. Asterixis is the most common and reliable sign that hepatic encephalopathy is developing. Options 1, 2, and 4 are incorrect.

**Test-Taking Strategy:** Focus on the subject, the procedure for assessment of asterixis. Remember that asterixis is irregular flapping movements of the fingers and wrists. This will direct you to the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Health Promotion and Maintenance  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: GI Accessory Organs

546. Answer: 3

Rationale: Cirrhosis is a chronic, progressive disease of the liver characterized by diffuse degeneration and destruction of hepatocytes. The serum ammonia level assesses the ability of the liver to deaminate protein byproducts. Normal reference interval is 10 to 80 mcg/dL (6 to 47 mcmol/L). Most of the ammonia in the body is found in the gastrointestinal tract. Protein provided by the diet is transported to the liver by the portal vein. The liver breaks down protein, which results in the formation of ammonia. Foods high in protein should be avoided since the client’s ammonia level is elevated above the normal range; therefore, pasta with sauce would be the best selection.

Test-Taking Strategy: Focus on the subject, an ammonia level of 85 mcg/dL (51 mcmol/L). Realizing that this result is above the normal range will direct you away from selecting high-protein foods, such as pork, cheese, eggs, and fish.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Planning
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: GI Accessory Organs
Priority Concepts: Inflammation; Nutrition

547. Answer: 3

Rationale: A frequent symptom of duodenal ulcer is pain that is relieved by food intake. These clients generally describe the pain as a burning, heavy, sharp, or “hungry” pain that often localizes in the midepigastric area. The client with duodenal ulcer usually does not experience weight loss or nausea and vomiting. These symptoms are more typical in the client with a gastric ulcer.

Test-Taking Strategy: Eliminate options 1 and 2 because they are comparable or alike; if the client is vomiting, weight loss will occur. Next, think about the symptoms of duodenal and gastric ulcer. Choose the correct option over option 4, knowing that the pain does not radiate down the right arm and that a pattern of pain-food-relief occurs with duodenal ulcer.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: Upper GI Disorders
Priority Concepts: Clinical Judgment; Inflammation

548. Answer: 1
Rationale: Hiatal hernia is caused by a protrusion of a portion of the stomach above the diaphragm where the esophagus usually is positioned. The client usually experiences pain from reflux caused by ingestion of irritating foods, lying flat following meals or at night, and eating large or fatty meals. Relief is obtained with the intake of small, frequent, and bland meals; use of H₂-receptor antagonists and antacids; and elevation of the thorax following meals and during sleep.

Test-Taking Strategy: Focus on the subject, the action contraindicated in hiatal hernia. Thinking about the pathophysiology that occurs in hiatal hernia will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: Upper GI Disorders
Priority Concepts: Client Education; Pain

549. Answer: 2

Rationale: Ischemia of the stoma would be associated with a dusky or bluish or purple color. A beefy red and shiny stoma is normal and expected. Skin excoriation needs to be addressed and treated but does not require as immediate attention as purple discoloration of the stoma. Semiformed stool is a normal finding.

Test-Taking Strategy: Note the strategic word, immediate, and focus on the subject, the observation that requires primary health care provider notification. Note the words purple discoloration in option 2. Recall that purple indicates ischemia.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: Lower GI Disorders
Priority Concepts: Clinical Judgment; Tissue Integrity

550. Answer: 1

Rationale: As peristalsis returns following creation of a colostomy, the client begins to pass malodorous flatus. This indicates returning bowel function and is an expected event. Within 72 hours of surgery, the client should begin passing stool via the colostomy. Options 2, 3, and 4 are incorrect interpretations.

Test-Taking Strategy: Focus on the subject, that the client is passing flatus from the stoma. Think about the normal functioning of the gastrointestinal tract and note the time frame in the question to assist in answering correctly.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: Lower GI Disorders
Priority Concepts: Clinical Judgment; Elimination

551. Answer: 4

Rationale: A frequent complication that occurs following ileostomy is fluid and electrolyte imbalance. The client requires constant monitoring of intake and output to prevent this from occurring. Losses require replacement by intravenous infusion until the client can tolerate a diet orally. Intestinal obstruction is a less frequent complication. Fat malabsorption and folate deficiency are complications that could occur later in the postoperative period.

Test-Taking Strategy: Note the strategic word, most. Also note the subject, an ileostomy. Remember that ileostomy drainage is liquid, placing the client at risk for fluid and electrolyte imbalance.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: Lower GI Disorders
Priority Concepts: Clinical Judgment; Elimination

552. Answer: 1

Rationale: IBS is a functional gastrointestinal disorder that causes chronic or recurrent diarrhea, constipation, and/or abdominal pain and bloating. Dietary fiber and bulk help produce bulky, soft stools and establish regular bowel elimination habits. Therefore, the client should consume a high-fiber diet. Eating regular meals, drinking 8 to 10 cups of liquid a day, and chewing food slowly help promote normal bowel function. Medication therapy depends on the main symptoms of IBS. Bulk-forming laxatives or antidiarrheal agents or other agents may be prescribed.

Test-Taking Strategy: Note the strategic words, need for further teaching. These words indicate a negative event query and the need to select the incorrect client statement. Think about the pathophysiology associated with IBS to answer correctly. Also, note the word limit in option 1. With IBS, dietary fiber and bulk is important to assist in controlling symptoms.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: Lower GI Disorders

Priority Concepts: Elimination; Nutrition
Gastrointestinal Medications

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Inflammation; Tissue Integrity

I. Antacids (Table 49-1; Fig. 49-1)
   A. React with gastric acid to produce neutral salts or salts of low acidity
   B. Inactivate pepsin and enhance mucosal protection but do not coat the ulcer crater
   C. These medications are used for peptic ulcer disease and gastroesophageal reflux disease.
   D. These medications should be taken on a regular schedule; some are prescribed to be taken 1 and 3 hours after each meal and at bedtime.
   E. To provide maximum benefit, treatment should elevate the gastric pH above 5.
   F. Antacid tablets should be chewed thoroughly and followed with a glass of water or milk.
   G. Liquid preparations should be shaken before dispensing.

To prevent interactions with other medications and interference with the action of other medications, allow 1 hour between antacid administration and the administration of other medications.

II. Gastric Protectants
   A. Misoprostol
      1. An antisecretory medication that enhances mucosal defenses
      2. Suppresses secretion of gastric acid and maintains submucosal blood flow by promoting vasodilation
      3. Used to prevent gastric ulcers caused by nonsteroidal antiinflammatory drugs and aspirin
      4. Administered with meals

1544
B. Sucralfate
1. Creates a protective barrier against acid and pepsin
2. Administered orally; should be taken on an empty stomach
3. May cause constipation
4. May impede absorption of warfarin sodium, phenytoin, theophylline, digoxin, and some antibiotics; should be administered at least 2 hours apart from these medications

III. Histamine (H₂)-Receptor Antagonists
A. Description
1. Suppress secretion of gastric acid
2. Alleviate symptoms of heartburn and assist in preventing complications of peptic ulcer disease
3. Prevent stress ulcers and reduce the recurrence of all ulcers
4. Promote healing in gastroesophageal reflux disease
5. Are contraindicated in hypersensitive clients
6. Should be used with caution in clients with impaired renal or hepatic function

B. Cimetidine
1. Can be administered orally, intramuscularly, or intravenously
2. Food reduces the rate of absorption; if taken orally with meals, absorption will be slowed.
3. Intravenous administration can cause hypotension and dysrhythmias.
4. Antacids can decrease the absorption of oral cimetidine.
5. Cimetidine and antacids should be administered at least 1 hour apart from each other.
6. Cimetidine passes the blood–brain barrier, and central nervous system side and adverse effects can occur; it may cause mental confusion, agitation, psychosis,
depression, anxiety, and disorientation.

7. Dosage should be reduced in clients with renal impairment.
8. Cimetidine inhibits hepatic drug-metabolizing enzymes and can cause many medication levels to rise; if administered with warfarin sodium, phenytoin, theophylline, or lidocaine, the dosages of these medications should be reduced.

C. Ranitidine
1. Can be administered orally, intramuscularly, or intravenously
2. Side effects are uncommon, and it does not penetrate the blood–brain barrier as cimetidine does.
3. Ranitidine is not affected by food.

D. Famotidine and nizatidine
1. Famotidine and nizatidine are similar to ranitidine and cimetidine.
2. These medications do not need to be administered with food.

IV. Proton Pump Inhibitors (Box 49-1)
A. Suppress gastric acid secretion
B. Used to treat active ulcer disease, erosive esophagitis, and pathological hypersecretory conditions
C. Contraindicated in hypersensitivity
D. Common side effects include headache, diarrhea, abdominal pain, and nausea.

V. Medication Regimens to Treat *Helicobacter pylori* Infections (Box 49-2)
A. An antibacterial agent alone is not effective for eradicating *H. pylori*, because the bacterium readily becomes resistant to the agent.
B. Triple or quadruple therapy with a variety of medication combinations is used (if triple therapy fails, quadruple therapy is recommended).

VI. Prokinetic Agent
A. Medication: Metoclopramide
B. Stimulates motility of the upper gastrointestinal tract and increases the rate of gastric emptying without stimulating gastric, biliary, or pancreatic secretions
C. Used to treat gastroesophageal reflux and paralytic ileus
D. May cause restlessness, drowsiness, extrapyramidal reactions, dizziness, insomnia, and headache
E. Usually administered 30 minutes before meals and at bedtime
F. Contraindicated in clients with sensitivity and in clients
with mechanical obstruction, perforation, or gastrointestinal hemorrhage

G. Can precipitate hypertensive crisis in clients with pheochromocytoma
H. Safety in pregnancy has not been established
I. Metoclopramide can cause parkinsonian reactions; if this occurs, the medication will be discontinued by the health care provider.
J. Anticholinergics, such as atropine, and opioid analgesics, such as morphine, antagonize the effects of metoclopramide.
K. Alcohol, sedatives, cyclosporine, and tranquilizers produce an additive effect.

VII. Bile Acid Sequestrants (Box 49-3)
A. Act by absorbing and combining with intestinal bile salts, which then are secreted in the feces, preventing intestinal reabsorption
B. Used to treat hypercholesterolemia in adults, biliary obstruction, and pruritus associated with biliary disease
C. With powdered forms, taste and palatability are often reasons for noncompliance and can be improved by the use of flavored products or mixing the medication with various juices.
D. Side and adverse effects include nausea, bloating, constipation, fecal impaction, and intestinal obstruction.
E. Stool softeners and other sources of fiber can be used to abate the gastrointestinal side effects.

Bile acid sequestrants should be used cautiously in clients with suspected bowel obstruction or severe constipation because they can worsen these conditions.

VIII. Treating Hepatic Encephalopathy
A. Medication: Lactulose
B. Used in the prevention and treatment of portal systemic encephalopathy, including hepatic precoma and coma; also used in the treatment of chronic constipation
C. Promotes increased peristalsis and bowel evacuation, expelling ammonia from the colon and thus lowering the ammonia level (normal ammonia reference interval is 10 to 80 mcg/dL [6 to 47 mcmol/L])
D. Improves protein tolerance in clients with advanced hepatic cirrhosis
E. Administered orally in the form of a syrup or rectally

IX. Pancreatic Enzyme Replacements
A. Pancrelipase
B. Used to supplement or replace pancreatic enzymes and thus improve nutritional status and reduce the amount of fatty stools (a
deficiency of pancreatic enzymes can compromise digestion, especially the digestion of fats)

C. Should be taken with all meals and snacks

D. Side and adverse effects include abdominal cramps or pain, nausea, vomiting, and diarrhea.

E. Products that contain calcium carbonate or magnesium hydroxide interfere with the action of these medications.

X. Treatment for Inflammatory Bowel Disease (Box 49-4)

A. Inflammatory bowel disease has 2 forms, Crohn’s disease and ulcerative colitis.

B. Antimicrobials: May be prescribed to prevent or treat secondary infection (see Chapter 63 for information on antimicrobials)

C. 5-Aminosalicylates (5-ASAs): Decrease gastrointestinal inflammation; side and adverse effects include nausea, rash, arthralgia, and hematological disorders.

D. Corticosteroids: Act as an antiinflammatory to decrease gastrointestinal inflammation (see Chapter 47 for information on glucocorticoids and corticosteroids)

E. Immunomodulators: Monoclonal antibodies modulate the immune response to induce and maintain remission (see Box 49-4 for specific immunomodulators).

XI. Treatment for Irritable Bowel Syndrome (IBS)

A. Irritable bowel syndrome is a gastrointestinal disorder that is characterized by crampy abdominal pain accompanied by diarrhea, constipation, or both.

B. Pharmacological treatment depends on the main symptom, constipation or diarrhea.

C. Constipation-predominant IBS (IBS-C) treatment

1. Bulk-forming laxatives, usually taken at mealtimes with a full glass of water.

2. Lubiprostone: Chloride channel activator that increases fluid in the intestines to promote bowel elimination; needs to be taken with food and water.

3. Linaclotide: Stimulates receptors in the intestines to promote bowel transit time; taken daily 30 minutes before breakfast.

4. See Box 49-6 for a list of additional medications to treat constipation.

D. Diarrhea-predominant IBS (IBS-D) treatment

1. Alosetron

   a. A selective serotonin receptor antagonist

   b. Can cause adverse effects such as constipation, impaction, bowel obstruction, perforation of the bowel, and ischemic colitis.

   c. A strict risk management procedure
must be followed, including monitoring for serious adverse effects, reporting them, and immediate discontinuation of the medication if they arise.

2. Antidiarrheal medications: See Box 49-7 for a list of additional medications to treat diarrhea.

XII. Antiemetics (Box 49-5)
   A. Medications used to control vomiting and motion sickness
   B. The choice of the antiemetic is determined by the cause of the nausea and vomiting.
   C. Monitor vital signs and intake and output and for signs of dehydration and fluid and electrolyte imbalances.
   D. Limit odors in the client’s room when the client is nauseated or vomiting.
   E. Limit oral intake to clear liquids when the client is nauseated or vomiting.

![Antiemetics can cause drowsiness; therefore, a priority intervention is to protect the client from injury.]

XIII. Laxatives (see Box 49-6)
   A. Bulk-forming
      1. Description
         a. Absorb water into the feces and increase bulk to produce large and soft stools
         b. Contraindicated in bowel obstruction
         c. Dependency can occur with long-term use.
      2. Side and adverse effects include gastrointestinal disturbances, dehydration, and electrolyte imbalances.
   B. Stimulants: Stimulate motility of large intestine
   C. Emollients
      1. Inhibit absorption of water so fecal mass remains large and soft
      2. Used to avoid straining
   D. Osmotics: Attract water into the large intestine to produce bulk and stimulate peristalsis

![The client receiving a laxative needs to increase fluid intake to prevent dehydration.]

XIV. Medications to Control Diarrhea (see Box 49-7)
A. Identify and treat the underlying cause, treat dehydration, replace fluids and electrolytes, relieve abdominal discomfort and cramping, and reduce the passage of stool.

B. Opioids

1. Opioids are effective antidiarrheal medications that decrease intestinal motility and peristalsis.

2. When poisons, infections, or bacterial toxins are the cause of the diarrhea, opioids worsen the condition by delaying the elimination of toxins.

Table 49-1
Classification of Antacids and Considerations

<table>
<thead>
<tr>
<th>Classification</th>
<th>Considerations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aluminum compounds</td>
<td>Aluminum hydroxide is used to treat hyperphosphatemia; therefore, it can cause hypophosphatemia.</td>
</tr>
<tr>
<td></td>
<td>Aluminum hydroxide can reduce the effects of tetracyclines, warfarin sodium, and digoxin and can reduce phosphate absorption and thereby cause hypophosphatemia.</td>
</tr>
<tr>
<td></td>
<td>Aluminum compounds contain significant amounts of sodium; they should be used with caution in clients with hypertension and heart failure.</td>
</tr>
<tr>
<td></td>
<td>The most common side effect is constipation.</td>
</tr>
<tr>
<td>Magnesium compounds</td>
<td>Magnesium hydroxide is also a saline laxative, and the most prominent side effect is diarrhea; it is usually administered in combination with aluminum hydroxide, an antacid that assists in preventing diarrhea.</td>
</tr>
<tr>
<td></td>
<td>Magnesium compounds are contraindicated in clients with intestinal obstruction, appendicitis, or undiagnosed abdominal pain.</td>
</tr>
<tr>
<td></td>
<td>In clients with renal impairment, magnesium can accumulate to high levels, causing signs of toxicity.</td>
</tr>
<tr>
<td>Calcium compounds</td>
<td>Calcium carbonate can cause acid rebound.</td>
</tr>
<tr>
<td></td>
<td>Calcium compounds are rapid acting and release carbon dioxide in the stomach, causing belching and flatulence.</td>
</tr>
<tr>
<td></td>
<td>A common side effect is constipation. Milk-alkali syndrome (headache, urinary frequency, anorexia, nausea/vomiting, fatigue) can occur (the client should avoid milk products and vitamin D supplements).</td>
</tr>
<tr>
<td>Sodium bicarbonate</td>
<td>Sodium bicarbonate has a rapid onset, liberates carbon dioxide, increases intra-abdominal pressure, and promotes flatulence.</td>
</tr>
<tr>
<td></td>
<td>Sodium bicarbonate should be used with caution in clients with hypertension and heart failure.</td>
</tr>
<tr>
<td></td>
<td>Sodium bicarbonate can cause systemic alkalosis in clients with renal impairment.</td>
</tr>
<tr>
<td></td>
<td>Sodium bicarbonate is useful for treating acidosis and elevating urinary pH to promote excretion of acidic medications following overdose.</td>
</tr>

FIG. 49-1  Pathophysiological components of peptic ulcer. *H. pylori, Helicobacter pylori; NSAIDs, nonsteroidal antinflammatory drugs.*

**Box 49-1**

**Proton Pump Inhibitors**

- Esomeprazole
- Dexlansoprazole
- Lansoprazole
- Omeprazole
- Pantoprazole
- Rabeprazole

**Box 49-2**
Medication Regimens to Treat *Helicobacter pylori* Infections

**Triple Therapy**
- Esomeprazole, amoxicillin, clarithromycin
- Lansoprazole, amoxicillin, clarithromycin
- Esomeprazole, metronidazole, clarithromycin

**Quadruple Therapies**
- Esomeprazole, metronidazole, tetracycline, bismuth subsalicylate

*Note: Additional medications may be prescribed for each level of therapy.*

**Box 49-3**

**Bile Acid Sequestrants**
- Colesevelam
- Colestipol
- Cholestyramine

**Box 49-4**

**Medications to Treat Inflammatory Bowel Disease**

**Antimicrobials**
- Ciprofloxacin
- Metronidazole
- Rifaximin
- Clarithromycin

**5-Aminosalicylates**
- Balsalazide
- Mesalamine
- Olsalazine
- Sulfasalazine
Corticosteroids

- Budesonide
- Prednisone
- Hydrocortisone

Immunosuppressants

- Azathioprine
- Cyclosporine
- Mercaptopurine
- Tacrolimus

Immunomodulators

- Adalimumab
- Certolizumab
- Infliximab
- Natalizumab

Box 49-6

Laxatives

Bulk-Forming

- Methylcellulose
- Polycarbophil
- Psyllium

Stimulants

- Bisacodyl
- Senna

Emollient

- Docusate sodium

Osmotics

- Magnesium hydroxide
- Magnesium citrate
- Sodium phosphates
- Polyethylene glycol and electrolytes
- Lactulose

**Box 49-7**

**Medications to Control Diarrhea**

**Opioids and Related Medications**

- Diphenoxylate with atropine sulfate
- Loperamide

**Other Antidiarrheals**

- Bismuth subsalicylate
- Bulk-forming medications
- Anticholinergic antispasmodics: dicyclomine, glycopyrrolate

**Box 49-5**

**Commonly Administered Antiemetics**

**Serotonin Antagonists**

- Dolasetron
- Granisetron
- Ondansetron

**Glucocorticoids**

- Dexamethasone
- Methylprednisolone

**Substance P/Neurokinin-1 Antagonists**

- Aprepitant
- Fosaprepitant
- Rolapitant

**Benzodiazepine**
• Lorazepam

**Dopamine Antagonists**

**Phenothiazines**

• Chlorpromazine
• Perphenazine
• Prochlorperazine
• Promethazine

**Butyrophenones**

• Haloperidol
• Droperidol

**Others**

• Metoclopramide
• Trimethobenzamide

**Cannabinoids**

• Dronabinol
• Nabilone

**Anticholinergics**

• Scopolamine transdermal

**Antihistamines**

• Cyclizine
• Dimenhydrinate
• Diphenhydramine
• Hydroxyzine
• Meclizine hydrochloride

**Practice Questions**

554. A client with Crohn’s disease is scheduled to receive an infusion of infliximab. What intervention by the nurse will determine the **effectiveness** of treatment?
1. Monitoring the leukocyte count for 2 days after the infusion
2. Checking the frequency and consistency of bowel movements
3. Checking serum liver enzyme levels before and after the infusion
4. Carrying out a Hematest on gastric fluids after the infusion is completed

555. A client has an as needed prescription for loperamide hydrochloride. For which condition should the nurse administer this medication?
   1. Constipation
   2. Abdominal pain
   3. An episode of diarrhea
   4. Hematest-positive nasogastric tube drainage

556. A client has an as-needed prescription for ondansetron. For which condition(s) should the nurse administer this medication?
   1. Paralytic ileus
   2. Incisional pain
   3. Urinary retention
   4. Nausea and vomiting

557. A client has begun medication therapy with pancrelipase. The nurse evaluates that the medication is having the optimal intended benefit if which effect is observed?
   1. Weight loss
   2. Relief of heartburn
   3. Reduction of steatorrhea
   4. Absence of abdominal pain

558. An older client recently has been taking cimetidine. The nurse monitors the client for which most frequent central nervous system side effect of this medication?
   1. Tremors
   2. Dizziness
   3. Confusion
   4. Hallucinations

559. A client with a gastric ulcer has a prescription for sucralfate 1 gram by mouth 4 times daily. The nurse should schedule the medication for which times?
   1. With meals and at bedtime
   2. Every 6 hours around the clock
   3. One hour after meals and at bedtime
   4. One hour before meals and at bedtime

560. A client who uses nonsteroidal antiinflammatory drugs (NSAIDs) has been taking misoprostol. The nurse determines that the misoprostol is having the intended therapeutic effect if which finding is noted?
   1. Resolved diarrhea
   2. Relief of epigastric pain
   3. Decreased platelet count
   4. Decreased white blood cell count

561. A client has been taking omeprazole for 4 weeks. The ambulatory care nurse evaluates that the client is receiving the optimal intended effect of the medication if the client reports the absence of which symptom?
   1. Diarrhea
2. Heartburn
3. Flatulence
4. Constipation

562. A client with a peptic ulcer is diagnosed with a *Helicobacter pylori* infection. The nurse is teaching the client about the medications prescribed, including clarithromycin, esomeprazole, and amoxicillin. Which statement by the client indicates the best understanding of the medication regimen?

1. “My ulcer will heal because these medications will kill the bacteria.”
2. “These medications are only taken when I have pain from my ulcer.”
3. “The medications will kill the bacteria and stop the acid production.”
4. “These medications will coat the ulcer and decrease the acid production in my stomach.”

563. A client has a new prescription for metoclopramide. On review of the chart, the nurse identifies that this medication can be safely administered with which condition?

1. Intestinal obstruction
2. Peptic ulcer with melena
3. Diverticulitis with perforation
4. Vomiting following cancer chemotherapy

564. The nurse determines the client needs further instruction on cimetidine if which statements were made? Select all that apply.

- [ ] 1. “I will take the cimetidine with my meals.”
- [ ] 2. “I’ll know the medication is working if my diarrhea stops.”
- [ ] 3. “My episodes of heartburn will decrease if the medication is effective.”
- [ ] 4. “Taking the cimetidine with an antacid will increase its effectiveness.”
- [ ] 5. “I will notify my primary health care provider if I become depressed or anxious.”
- [ ] 6. “Some of my blood levels will need to be monitored closely since I also take warfarin for atrial fibrillation.”

565. The nurse has given instructions to a client who has just been prescribed cholestyramine. Which statement by the client indicates a need for further instruction?

1. “I will continue taking vitamin supplements.”
2. “This medication will help lower my cholesterol.”
3. “This medication should only be taken with water.”
4. “A high-fiber diet is important while taking this medication.”

**Answers**
Rationale: The principal manifestations of Crohn’s disease are diarrhea and abdominal pain. Infliximab is an immunomodulator that reduces the degree of inflammation in the colon, thereby reducing the diarrhea. Options 1, 3, and 4 are unrelated to this medication.

Test-Taking Strategy: Focus on the subject, treatment for Crohn’s disease, and note the strategic word, effectiveness. Eliminate option 4, because gastric bleeding is not a characteristic of Crohn’s disease. Monitoring the leukocyte count and liver enzyme levels is appropriate when infliximab is given but not to evaluate the effectiveness of treatment, eliminating options 1 and 3.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Pharmacology: Immune Medications: Immunosuppressants
Health Problem: Adult Health: Gastrointestinal: Lower GI disorders
Priority Concepts: Evidence; Immunity

Rationale: Loperamide is an antidiarrheal agent. It is used to manage acute and chronic diarrhea in conditions such as inflammatory bowel disease. Loperamide also can be used to reduce the volume of drainage from an ileostomy. It is not used for the conditions in options 1, 2, and 4.

Test-Taking Strategy: Focus on the subject, the action of loperamide. Recalling that this medication is an antidiarrheal agent will direct you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Pharmacology: Gastrointestinal Medications: Antidiarrheals
Health Problem: Adult Health: Gastrointestinal: Lower GI disorders
Priority Concepts: Clinical Judgment; Elimination

Rationale: Ondansetron is an antiemetic used to treat postoperative nausea and vomiting, as well as nausea and vomiting associated with chemotherapy. The other options are incorrect reasons for administering this medication.

Test-Taking Strategy: Focus on the subject, the action of ondansetron. Recalling that this medication is an antiemetic will direct you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Pharmacology: Gastrointestinal Medications: Antiemetics
Health Problem: Adult Health: Gastrointestinal: Upper GI disorders
**Priority Concepts:** Clinical Judgment; Fluids and Electrolytes

**Reference:** Lewis et al. (2017), p. 895.

**557. Answer:** 3

**Rationale:** Pancrelipase is a pancreatic enzyme used in clients with pancreatitis as a digestive aid. The medication should reduce the amount of fatty stools (steatorrhea). Another intended effect could be improved nutritional status. It is not used to treat abdominal pain or heartburn. Its use could result in weight gain but should not result in weight loss if it is aiding in digestion.

**Test-Taking Strategy:** Focus on the subject, intended benefit of the medication and on the name of the medication. Use knowledge of physiology of the pancreas and the function of pancreatic enzymes to assist in directing you to the correct option.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Evaluation

**Content Area:** Pharmacology: Gastrointestinal Medications: Pancreatic enzymes

**Health Problem:** Adult Health: Gastrointestinal: GI Accessory organs

**Priority Concepts:** Elimination; Inflammation

**558. Answer:** 3

**Rationale:** Cimetidine is a histamine (H₂)-receptor antagonist. Older clients are especially susceptible to central nervous system side effects of cimetidine. The most frequent of these is confusion. Less common central nervous system side effects include headache, dizziness, drowsiness, and hallucinations.

**Test-Taking Strategy:** Note the strategic word, most. Use knowledge of the older client and medication effects to direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Pharmacology: Gastrointestinal Medications: Histamine (H₂)-receptor antagonists

**Health Problem:** Adult Health: Gastrointestinal: Upper GI disorders

**Priority Concepts:** Clinical Judgment; Safety

**Reference:** Lewis et al. (2017), p. 903.

**559. Answer:** 4

**Rationale:** Sucralfate is a gastric protectant. The medication should be scheduled for administration 1 hour before meals and at bedtime. The medication is timed to allow it to form a protective coating over the ulcer before food intake stimulates gastric acid production and mechanical irritation. The other options are incorrect.

**Test-Taking Strategy:** Focus on the subject, times to administer sucralfate. Note the client’s diagnosis and think about the pathophysiology associated with a gastric
ulcer to assist in directing you to the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Pharmacology: Gastrointestinal Medications: Gastric protectants  
**Health Problem:** Adult Health: Gastrointestinal: Upper GI disorders  
**Priority Concepts:** Clinical Judgment; Tissue Integrity  

560. **Answer:** 2

**Rationale:** The client who uses NSAIDs is prone to gastric mucosal injury. Misoprostol is a gastric protectant and is given specifically to prevent this occurrence in clients taking NSAIDs frequently. Diarrhea can be a side effect of the medication but is not an intended effect. Options 3 and 4 are unrelated to the purpose of misoprostol.

**Test-Taking Strategy:** Focus on the **subject**, the intended therapeutic effect of misoprostol for a client who chronically uses NSAIDs. This indicates that the medication is being given to prevent the occurrence of specific symptoms. Recalling that NSAIDs can cause gastric mucosal injury will direct you to the correct option.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Pharmacology: Gastrointestinal Medications: Gastric protectants  
**Health Problem:** Adult Health: Gastrointestinal: Upper GI disorders  
**Priority Concepts:** Evidence; Tissue Integrity  
**Reference:** Lewis et al. (2017), pp. 903, 914.

561. **Answer:** 2

**Rationale:** Omeprazole is a proton pump inhibitor classified as an antiulcer agent. The intended effect of the medication is relief of pain from gastric irritation, often called *heartburn* by clients. Omeprazole is not used to treat the conditions identified in options 1, 3, and 4.

**Test-Taking Strategy:** Focus on the **subject**, the optimal intended effect of omeprazole. Recalling that this medication is a proton pump inhibitor will direct you to the correct option.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Pharmacology: Gastrointestinal Medications: Proton pump inhibitors  
**Health Problem:** Adult Health: Gastrointestinal: Upper GI disorders  
**Priority Concepts:** Evidence; Tissue Integrity  

562. **Answer:** 3
Rationale: Triple therapy for H. pylori infection usually includes 2 antibacterial medications and a proton pump inhibitor. Clarithromycin and amoxicillin are antibacterials. Esomeprazole is a proton pump inhibitor. These medications will kill the bacteria and decrease acid production.

Test-Taking Strategy: Focus on the subject, the medications and their actions, and note the strategic word, best. Eliminate option 1 because the medications do more than kill the bacteria. These medications are taken not only when there is pain but continually until gone, usually for 1 to 2 weeks. This will eliminate option 2. These medications do not coat the ulcer, eliminating option 4.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Pharmacology: Gastrointestinal Medications: Helicobacter pylori infection medications
Health Problem: Adult Health: Gastrointestinal: Upper GI disorders
Priority Concepts: Client Education; Infection

Answer: 4

Rationale: Metoclopramide is a gastrointestinal stimulant and antiemetic. Because it is a gastrointestinal stimulant, it is contraindicated with gastrointestinal obstruction, hemorrhage, or perforation. It is used in the treatment of vomiting after surgery, chemotherapy, or radiation.

Test-Taking Strategy: Focus on the subject, safe use of metoclopramide. Recalling the classification and action of this medication and that it is an antiemetic will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Pharmacology: Gastrointestinal Medications: Antiemetics
Health Problem: Adult Health—Gastrointestinal: Upper GI disorders
Priority Concepts: Clinical Judgment; Safety

Answer: 1, 2, 4

Rationale: Cimetidine, a histamine (H₂)-receptor antagonist, helps alleviate the symptom of heartburn, not diarrhea. Because cimetidine crosses the blood–brain barrier, central nervous system side and adverse effects, such as mental confusion, agitation, depression, and anxiety, can occur. Food reduces the rate of absorption, so if cimetidine is taken with meals, absorption will be slowed. Antacids decrease the absorption of cimetidine and should be taken at least 1 hour apart. If cimetidine is concomitantly administered with warfarin therapy, warfarin doses may need to be reduced, so prothrombin and international normalized ratio results must be followed.

Test-Taking Strategy: Note the strategic words, needs further instruction. These
words indicate a negative event query and ask you to select the options that are incorrect statements. Think about the therapeutic effect, adverse effects, and potential medication interactions to direct you to the correct options.

**Level of Cognitive Ability:** Evaluating
**Client Needs:** Physiological Integrity
**Integrated Process:** Teaching and Learning
**Content Area:** Pharmacology: Gastrointestinal Medications: Histamine (H₂)-receptor antagonists

**Health Problem:** Adult Health: Gastrointestinal: Upper GI disorders
**Priority Concepts:** Client Education; Safety
**Reference:** Hodgson, Kizior (2018), pp. 244-245.

565. **Answer:** 3

**Rationale:** Cholestyramine is a bile acid sequestrant used to lower the cholesterol level, and client compliance is a problem because of its taste and palatability. The use of flavored products or fruit juices can improve the taste. Some side effects of bile acid sequestrants include constipation and decreased vitamin absorption.

**Test-Taking Strategy:** Note the strategic words, need for further instruction. These words indicate a negative event query and ask you to select an option that is an incorrect statement. Note the closed-ended word “only” in the correct option.

**Level of Cognitive Ability:** Evaluating
**Client Needs:** Physiological Integrity
**Integrated Process:** Teaching and Learning
**Content Area:** Pharmacology: Gastrointestinal Medications: Bile acid sequestrants
**Health Problem:** Adult Health: Gastrointestinal: GI Accessory organs
**Priority Concepts:** Client Education; Safety
**Reference:** Lewis et al. (2017), p. 711.
Introduction

Pyramid to Success

The Pyramid to Success focuses on infectious diseases, particularly tuberculosis, and respiratory care in relation to respiratory problems. Pyramid Points focus on the client with pneumonia, respiratory failure, chronic obstructive pulmonary disease, pneumothorax, influenza, and tuberculosis. The Pyramid to Success includes the care of the client with tuberculosis, especially regarding the importance of the medication regimen, providing adequate nutrition and adequate rest to promote the healing process, and prevention of transmission and progression of the disease. Focus on assisting the client to cope with the social isolation issues that exist during the period of illness and on teaching the client and family the critical measures of screening, preventing respiratory disease, and the transmission of infectious airborne disease. Another important area to consider is caring for a client with an acute pulmonary process such as pulmonary embolism.

Client Needs: Learning Objectives

Safe and Effective Care Environment

- Collaborating with the interprofessional team in the management of the respiratory problem
- Discussing consultations and referrals related to the respiratory problem
- Ensuring that informed consent related to invasive procedures has been obtained
- Establishing priorities
- Handling infectious materials such as sputum or body fluids safely
- Maintaining confidentiality related to the respiratory disorder
- Maintaining respiratory precautions, standard precautions, and other precautions

Health Promotion and Maintenance

- Educating the client about adequate fluid and nutritional intake
- Educating the client about breathing exercises and respiratory therapy and care
- Educating the client about medication administration
- Educating the client about the need for follow-up care
- Educating the client about the prevention of transmission of infection
Informing the client about health promotion programs
Performing respiratory assessment techniques
Preventing respiratory problems and infectious diseases
Providing health screening related to risks for respiratory problems

**Psychosocial Integrity**

Considering religious, cultural, and spiritual influences when providing care
Discussing body image changes related to respiratory problems
Discussing end-of-life and grief and loss issues
Discussing situational role changes
Identifying coping strategies
Identifying support systems and community resources

**Physiological Integrity**

Administering medications
Managing respiratory illnesses
Monitoring for acid-base imbalances
Monitoring for alterations in body systems
Monitoring for infectious diseases
Providing nutrition and oral hygiene
Providing personal hygiene and promoting rest and sleep
Providing comfort
CHAPTER 50

Respiratory Problems

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Gas Exchange; Perfusion

I. Anatomy and Physiology
   A. Primary functions of the respiratory system
      1. Provides oxygen for metabolism in the tissues
      2. Removes carbon dioxide, the waste product of metabolism
   B. Secondary functions of the respiratory system
      1. Facilitates sense of smell
      2. Produces speech
      3. Maintains acid–base balance
      4. Maintains body water levels
      5. Maintains heat balance
   C. Upper respiratory airway
      1. Nose: Humidifies, warms, and filters inspired air
      2. Sinuses: Air-filled cavities within the hollow bones that surround the nasal passages and provide resonance during speech
      3. Pharynx
         a. Passageway for the respiratory and digestive tracts located behind the oral and nasal cavities
         b. Divided into the nasopharynx, oropharynx, and laryngopharynx
      4. Larynx
         a. Located just below the pharynx at the root of the tongue; commonly called the voice box
         b. Contains 2 pairs of vocal cords, the false and true cords
         c. The opening between the true vocal cords is the glottis. The glottis plays an important role in coughing, which is the most fundamental defense mechanism of the lungs.
      5. Epiglottis
a. Leaf-shaped elastic flap structure at the top of the larynx
b. Prevents food from entering the tracheobronchial tree by closing over the glottis during swallowing

D. Lower respiratory airway

1. Trachea: Located in front of the esophagus; branches into the right and left mainstem bronchi at the carina

2. Mainstem bronchi
   a. Begin at the carina
   b. The right bronchus is slightly wider, shorter, and more vertical than the left bronchus.
   c. Divide into secondary or lobar bronchi that enter each of the 5 lobes of the lung
   d. The bronchi are lined with cilia, which propel mucus up and away from the lower airway to the trachea, where it can be expectorated or swallowed.

3. Bronchioles
   a. Branch from the secondary bronchi and subdivide into the small terminal and respiratory bronchioles
   b. Contain no cartilage and depend on the elastic recoil of the lung for patency
   c. The terminal bronchioles contain no cilia and do not participate in gas exchange.

4. Alveolar ducts and alveoli
   a. Acinus (plural, acini) is a term used to indicate all structures distal to the terminal bronchiole.
   b. Branch from the respiratory bronchioles
   c. Alveolar sacs, which arise from the ducts, contain clusters of alveoli, which are the basic units of gas exchange.
   d. Type 2 alveolar cells in the walls of the alveoli secrete surfactant, a phospholipid protein that reduces the surface tension in the alveoli; without surfactant, the alveoli would collapse.

5. Lungs
   a. Located in the pleural cavity in the thorax
b. Extend from just above the clavicles to the diaphragm, the major muscle of inspiration.

c. The right lung, which is larger than the left, is divided into 3 lobes: the upper, middle, and lower lobes.

d. The left lung, which is narrower than the right lung to accommodate the heart, is divided into 2 lobes.

e. The respiratory structures are innervated by the phrenic nerve, the vagus nerve, and the thoracic nerves.

f. The parietal pleura lines the inside of the thoracic cavity, including the upper surface of the diaphragm.

g. The visceral pleura covers the pulmonary surfaces.

h. A thin fluid layer, which is produced by the cells lining the pleura, lubricates the visceral pleura and the parietal pleura, allowing them to glide smoothly and painlessly during respiration.

i. Blood flows throughout the lungs via the pulmonary circulation system.

6. Accessory muscles of respiration include the scalene muscles, which elevate the first 2 ribs; the sternocleidomastoid muscles, which raise the sternum; and the trapezius and pectoralis muscles, which fix the shoulders.

7. The respiratory process

a. The diaphragm descends into the abdominal cavity during inspiration, causing negative pressure in the lungs.

b. The negative pressure draws air from the area of greater pressure, the atmosphere, into the area of lesser pressure, the lungs.

c. In the lungs, air passes through the terminal bronchioles into the alveoli and diffuses into surrounding capillaries, then travels to the rest of the body to oxygenate the body tissues.

d. At the end of inspiration, the diaphragm and intercostal muscles relax and the lungs recoil.
e. As the lungs recoil, pressure within the lungs becomes higher than atmospheric pressure, causing the air, which now contains the cellular waste products carbon dioxide and water, to move from the alveoli in the lungs to the atmosphere.

f. Effective gas exchange depends on distribution of gas (ventilation) and blood (perfusion) in all portions of the lungs.

II. Diagnostic Tests

A. Risk factors for respiratory disorders (Box 50-1)

B. Chest x-ray film (radiograph)
   1. Description: Provides information regarding the anatomical location and appearance of the lungs
   2. Preprocedure
      a. Remove all jewelry and other metal objects from the chest area.
      b. Assess the client’s ability to inhale and hold his or her breath.
   3. Postprocedure: Help the client get dressed.

   Question women regarding pregnancy or the possibility of pregnancy before performing radiography studies.

C. Sputum specimen
   1. Description: Specimen obtained by expectoration or tracheal suctioning to assist in the identification of organisms or abnormal cells (see Priority Nursing Actions in Chapter 69)
   2. Preprocedure
      a. Determine the specific purpose of collection and check institutional policy for the appropriate method for collection.
      b. Obtain an early morning sterile specimen by suctioning or expectoration after a respiratory treatment if a treatment is prescribed.
      c. Instruct the client to rinse the mouth with water before collection.
      d. Obtain 15 mL of sputum.
      e. Instruct the client to take several deep breaths and then cough deeply to obtain sputum.
f. Collect the specimen before the client begins antibiotic therapy. If already started on antibiotic therapy, ensure the laboratory can utilize an antimicrobial removal device when analyzing the specimen.

3. Postprocedure
   a. If a culture of sputum is prescribed, transport the specimen to the laboratory immediately.
   b. Assist the client with mouth care.

Ensure that an informed consent was obtained for any invasive procedure. Vital signs are measured before the procedure and monitored postprocedure to detect signs of complications.

D. Laryngoscopy and bronchoscopy
   1. Description: Direct visual examination of the larynx, trachea, and bronchi with a fiberoptic bronchoscope
   2. Preprocedure
      a. Maintain NPO (nothing by mouth) status as prescribed.
      b. Assess the results of coagulation studies.
      c. Remove dentures and eyeglasses.
      d. Establish an intravenous (IV) access as necessary and administer medication for sedation as prescribed.
      e. Have emergency resuscitation supplies readily available.
   3. Postprocedure
      a. Maintain the client in a semi-Fowler’s position.
      b. Assess for the return of the gag reflex.
      c. Maintain NPO status until the gag reflex returns.
      d. Monitor for bloody sputum.
      e. Monitor respiratory status, particularly if sedation has been administered.
      f. Monitor for complications, such as bronchospasm or bronchial perforation, indicated by facial or neck crepitus, dysrhythmias, hemorrhage, hypoxemia, and pneumothorax.
g. Notify the primary health care provider (PHCP) if signs of complications occur.

E. Endobronchial ultrasound (EBUS)
1. Tissue samples are obtained from central lung masses and lymph nodes, using a bronchoscope with the help of ultrasound guidance.
2. Tissue samples are used for diagnosing and staging lung cancer, detecting infections, and identifying inflammatory diseases that affect the lungs, such as sarcoidosis.
3. Postprocedure, the client is monitored for signs of bleeding and respiratory distress.

F. Pulmonary angiography
1. Description
   a. A fluoroscopic procedure in which a catheter is inserted through the antecubital or femoral vein into the pulmonary artery or 1 of its branches
   b. Involves an injection of iodine or radiopaque contrast material
2. Preprocedure
   a. Assess for allergies to iodine, seafood, or other radiopaque dyes.
   b. Maintain NPO status as prescribed.
   c. Assess results of coagulation studies.
   d. Establish an IV access.
   e. Administer sedation as prescribed.
   f. Instruct the client to lie still during the procedure.
   g. Instruct the client that he or she may feel an urge to cough, flushing, nausea, or a salty taste following injection of the dye.
   h. Have emergency resuscitation equipment available.
3. Postprocedure
   a. Avoid taking blood pressures for 24 hours in the extremity used for the injection.
   b. Monitor peripheral neurovascular status of the affected extremity.
   c. Assess insertion site for bleeding.
   d. Monitor for reaction to the dye.

G. Thoracentesis
1. **Description:** Removal of fluid or air from the pleural space via transthoracic aspiration

2. **Preprocedure**
   a. Prepare the client for ultrasound or chest radiograph, if prescribed, before the procedure.
   b. Assess results of coagulation studies.
   c. Note that the client is positioned sitting upright, with the arms and shoulders supported by a table at the bedside during the procedure (Fig. 50-1).
   d. If the client cannot sit up, the client is placed lying in bed toward the unaffected side, with the head of the bed elevated.
   e. Instruct the client not to cough, breathe deeply, or move during the procedure.

3. **Postprocedure**
   a. Monitor respiratory status.
   b. Apply a pressure dressing, and assess the puncture site for bleeding and crepitus.
   c. Monitor for signs of pneumothorax, air embolism, and pulmonary edema.

**H. Pulmonary function tests**

1. **Description:** Tests used to evaluate lung mechanics, gas exchange, and acid–base disturbance through spirometric measurements, lung volumes, and arterial blood gas levels.

2. **Preprocedure**
   a. Determine whether an analgesic that may depress the respiratory function is being administered.
   b. Consult with the PHCP regarding withholding bronchodilators before testing, or alternatively if the testing will be done prior to and after administration of a bronchodilator.
   c. Instruct the client to void before the procedure and to wear loose clothing.
   d. Remove dentures.
   e. Instruct the client to refrain from smoking or eating a heavy meal for 4
to 6 hours before the test.

3. Postprocedure: The client may resume a normal diet and any bronchodilators and respiratory treatments that were withheld before the procedure.

I. Lung biopsy
   1. Description
      a. A transbronchial biopsy and a transbronchial needle aspiration may be performed to obtain tissue for analysis by culture or cytological examination.
      b. An open lung biopsy is performed in the operating room.
   2. Preprocedure
      a. Maintain NPO status as prescribed.
      b. Inform the client that a local anesthetic will be used for a needle biopsy, but a sensation of pressure during needle insertion and aspiration may be felt.
      c. Administer analgesics and sedatives as prescribed.
   3. Postprocedure
      a. Apply a dressing to the biopsy site and monitor for drainage or bleeding.
      b. Monitor for signs of respiratory distress, and notify the PHCP if they occur.
      c. Monitor for signs of pneumothorax and air emboli, and notify the PHCP if they occur.
      d. Prepare the client for chest radiography if prescribed.

J. Spiral (helical) computed tomography (CT) scan
   1. Frequently used test to diagnose pulmonary embolism
   2. IV injection of contrast medium is used; if the client cannot have contrast medium, a ventilation-perfusion (V/Q) scan will be done.
   3. The scanner rotates around the body, allowing for a 3-dimensional picture of all regions of the lungs.

K. V/Q lung scan
   1. Description
      a. The perfusion scan evaluates blood flow to the lungs.
      b. The ventilation scan determines the patency of the pulmonary airways and detects abnormalities in ventilation.
      c. A radionuclide may be injected for the
procedure.

2. Preprocedure
   a. Assess the client for allergies to dye, iodine, or seafood.
   b. Remove jewelry around the chest area.
   c. Review breathing methods that may be required during testing.
   d. Establish an IV access.
   e. Administer sedation if prescribed.
   f. Have emergency resuscitation equipment available.

3. Postprocedure
   a. Monitor the client for reaction to the radionuclide.
   b. Instruct the client that the radionuclide clears from the body in about 8 hours.
   c. Encourage increased fluid intake to clear the dye from the body if there is no fluid restriction.

L. Computed tomography pulmonary angiography
   1. Description
      a. The scan visualizes the pulmonary arteries and blood flow.
      b. Its main use is to diagnose pulmonary embolism and is the preferred method.
      c. A contrast dye is injected.

   2. Preprocedure: Similar to the V/Q lung scan; in addition, renal function should be adequate and dosing of the contrast should be done by a pharmacist.

   3. Postprocedure: Similar to the V/Q lung scan

M. Skin tests: A skin test uses an intradermal injection to help diagnose various infectious diseases (Box 50-2).

N. Arterial blood gases (ABGs)
   1. Description: Measurement of the dissolved oxygen and carbon dioxide in the arterial blood helps indicate the acid–base state and how well oxygen is being carried to the body.

Avoid suctioning the client before drawing an ABG sample, because the suctioning procedure will deplete the client’s oxygen, resulting in inaccurate ABG results.
O. Pulse oximetry: See Chapter 10.

P. D-dimer

1. A blood test that measures clot formation and lysis that results from the degradation of fibrin
2. Helps diagnose (a positive test result) the presence of thrombus in conditions such as deep vein thrombosis, pulmonary embolism, or stroke; it is also used to diagnose disseminated intravascular coagulation (DIC) and to monitor the effectiveness of treatment.
3. The normal D-dimer level is less than 50 ng/mL (less than 3.0 mmol/L); normal fibrinogen is 60 to 100 mg/dL (2.0 to 5.0 g/L).

III. Respiratory Treatments (see Chapter 69)

IV. Chest Injuries

A. Rib fracture

1. Description
   a. Results from direct blunt chest trauma and causes a potential for intrathoracic injury, such as pneumothorax, hemothorax, or pulmonary contusion
   b. Pain with movement, deep breathing, and coughing results in impaired ventilation and inadequate clearance of secretions.

2. Assessment
   a. Pain and tenderness at the injury site that increases with inspiration
   b. Shallow respirations
   c. Client splints chest
   d. Fractures noted on chest x-ray

3. Interventions
   a. Note that the ribs usually reunite spontaneously.
   b. Open reduction and internal fixation of the ribs (rib plating) may be done.
   c. Place the client in a Fowler’s position.
   d. Administer pain medication as prescribed to maintain adequate ventilatory status.
   e. Monitor for increased respiratory distress.
   f. Instruct the client to self-splint
B. Flail chest

1. Description

   a. Occurs from blunt chest trauma associated with accidents, which may result in hemothorax and rib fractures.

   b. The loose segment of the chest wall becomes paradoxical to the expansion and contraction of the rest of the chest wall.

2. Assessment

   a. Paradoxical respirations (inward movement of a segment of the thorax during inspiration with outward movement during expiration)

   b. Severe pain in the chest

   c. Dyspnea

   d. Cyanosis

   e. Tachycardia

   f. Hypotension

   g. Tachypnea, shallow respirations

   h. Diminished breath sounds

3. Interventions

   a. Maintain the client in a Fowler’s position.

   b. Administer oxygen as prescribed.

   c. Monitor for increased respiratory distress.

   d. Encourage coughing and deep breathing.

   e. Administer pain medication as prescribed.

   f. Maintain bed rest and limit activity to reduce oxygen demands.

   g. Open reduction and internal fixation of the ribs (rib plating) may be done.

   h. Prepare for intubation with **mechanical ventilation**, with positive end-expiratory pressure (PEEP) for severe flail chest associated with respiratory failure and shock (see
C. Pulmonary contusion

1. Description
a. Characterized by interstitial hemorrhage associated with intra-alveolar hemorrhage, resulting in decreased pulmonary compliance
b. The major complication is acute respiratory distress syndrome.

2. Assessment
a. Dyspnea
b. Restlessness
c. Increased bronchial secretions
d. Hypoxemia
e. Hemoptysis
f. Decreased breath sounds
g. Crackles and wheezes

3. Interventions
a. Maintain a patent airway and adequate ventilation.
b. Place the client in a Fowler’s position.
c. Administer oxygen as prescribed.
d. Monitor for increased respiratory distress.
e. Maintain bed rest and limit activity to reduce oxygen demands.
f. Prepare for mechanical ventilation with PEEP if required.

D. Pneumothorax (Fig. 50-2)

1. Description
a. Accumulation of atmospheric air in the pleural space, which results in a rise in intrathoracic pressure and reduced vital capacity, or the greatest amount of air expired from the lungs after taking a deep breath.
b. The loss of negative intrapleural pressure results in collapse of the lung.
c. A spontaneous pneumothorax occurs with the rupture of a pulmonary bleb, or small air-containing spaces deep in the lung.
d. An open pneumothorax occurs when an opening through the chest wall allows the entrance of positive atmospheric air pressure into the pleural space.
e. A tension pneumothorax occurs from a blunt chest injury or from mechanical ventilation with PEEP when a buildup of positive pressure occurs in the pleural space.

2. Assessment (Box 50-3)

3. Interventions

a. Diagnosis of pneumothorax is made by chest x-ray.
b. Apply a nonporous dressing over an open chest wound.
c. Administer oxygen as prescribed.
d. Place the client in a Fowler’s position.
e. Prepare for chest tube placement, which will remain in place until the lung has expanded fully.
f. Monitor the chest tube drainage system.
g. Monitor for subcutaneous emphysema.
h. See Chapter 69 for information on caring for a client with chest tubes.

V. Acute Respiratory Failure

A. Description

1. Occurs when insufficient oxygen is transported to the blood or inadequate carbon dioxide is removed from the lungs and the client’s compensatory mechanisms fail.
2. Causes include a mechanical abnormality of the lungs or chest wall, a defect in the respiratory control center in the brain, or an impairment in the function of the respiratory muscles.

3. In oxygenation failure, or hypoxemic respiratory failure, oxygen may reach the alveoli but cannot be absorbed or used properly, resulting in a PaO₂ lower than 60 mm Hg, arterial oxygen saturation (SaO₂) lower than 90%, or partial pressure
of arterial carbon dioxide (PaCO₂) greater than 50 mm Hg occurring with acidemia.

4. Respiratory failure can be hypoxemic, hypercapnic, or both. Inadequate gas exchange is the mechanism behind failure. Arterial oxygen, carbon dioxide, or both are not kept at normal levels, resulting in failure.

5. Many clients experience both hypoxemic and hypercapnic respiratory failure and retained carbon dioxide in the alveoli displaces oxygen, contributing to the hypoxemia.

6. Manifestations of respiratory failure are related to the extent and rapidity of change in PaO₂ and PaCO₂.

B. Assessment

1. Dyspnea
2. Restlessness
3. Confusion
4. Tachycardia
5. Hypertension
6. Dysrhythmias
7. Decreased level of consciousness
8. Alterations in respirations and breath sounds
9. Headache (less common)

C. Interventions

1. Identify and treat the cause of the respiratory failure.
2. Administer oxygen to maintain the PaO₂ level higher than 60 to 70 mm Hg.
3. Place the client in a Fowler’s position.
4. Encourage deep breathing.
5. Administer bronchodilators as prescribed.
6. Prepare the client for mechanical ventilation if supplemental oxygen cannot maintain acceptable PaO₂ and PaCO₂ levels.

VI. Acute Respiratory Distress Syndrome

A. Description

1. A form of acute respiratory failure that occurs as a complication caused by a diffuse lung injury or critical illness and leads to extravascular lung fluid.
2. The major site of injury is the alveolar capillary membrane.
3. The interstitial edema causes compression and obliteration of the terminal airways and leads to reduced lung volume and compliance.

4. The ABG levels identify respiratory acidosis and hypoxemia that do not respond to an increased percentage of oxygen.
5. The chest x-ray shows bilateral interstitial and alveolar infiltrates; interstitial edema may not be noted until there is a 30% increase in fluid content.
6. Causes include sepsis, fluid overload, shock, trauma, neurological injuries, burns, DIC, drug ingestion, aspiration, and inhalation of toxic substances.

B. Assessment
1. Tachypnea
2. Dyspnea
3. Decreased breath sounds
4. Deteriorating ABG levels
5. Hypoxemia despite high concentrations of delivered oxygen
6. Decreased pulmonary compliance
7. Pulmonary infiltrates

C. Interventions
1. Identify and treat the cause of the acute respiratory distress syndrome.
2. Administer oxygen as prescribed.
3. Place the client in a Fowler’s position.
4. Restrict fluid intake as prescribed.
5. Provide respiratory treatments as prescribed.
6. Administer diuretics, anticoagulants, or corticosteroids as prescribed.
7. Prepare the client for intubation and mechanical ventilation using PEEP.

VII. Asthma (Fig. 50-3)

A. Description
1. Chronic inflammatory disorder of the airways that causes varying degrees of obstruction in the airways
2. Marked by airway inflammation and hyper-responsiveness to a variety of stimuli or triggers (Box 50-4).
3. Causes recurrent episodes of wheezing, breathlessness, chest tightness, and coughing associated with airflow obstruction that may resolve spontaneously; it is often reversible with treatment.
4. Severity is classified based on the clinical features before treatment (Box 50-5).
5. Status asthmaticus is a severe life-threatening asthma episode that is refractory to treatment and may result in pneumothorax, acute cor pulmonale, or respiratory arrest.

Silent breath sounds are associated with acute asthma
exacerbation, may indicate impending respiratory failure due to diffuse bronchospasm, and is a life-threatening condition.

6. Refer to Chapter 35 for additional information on asthma.

B. Assessment

1. Restlessness
2. Wheezing or crackles
3. Absent or diminished lung sounds
4. Hyperresonance
5. Use of accessory muscles for breathing
6. Tachypnea with hyperventilation
7. Prolonged exhalation
8. Tachycardia
9. Pulsus paradoxus
10. Diaphoresis
11. Cyanosis
12. Decreased oxygen saturation
13. Pulmonary function test results that demonstrate decreased airflow rates

C. Interventions

1. Monitor vital signs.
2. Monitor pulse oximetry.
3. Monitor peak flow.
4. During an acute asthma episode, provide interventions to assist with breathing (Box 50-6).

D. Client education

1. On the intermittent nature of symptoms and need for long-term management
2. To identify possible triggers and measures to prevent episodes
3. About the management of medication and proper administration
4. About the correct use of a peak flowmeter
5. About developing an asthma action plan with the PHCP and what to do if an asthma episode occurs

VIII. Chronic Obstructive Pulmonary Disease

A. Description

1. Also known as chronic obstructive lung disease and chronic airflow limitation
2. **Chronic obstructive pulmonary disease** is a disease state characterized by airflow obstruction.
3. Chronic bronchitis and emphysema are progressive lung diseases that fall under the general category of chronic obstructive pulmonary disease.
4. Chronic bronchitis is a condition in which the
bronchial tubes become inflamed and excessive mucus production occurs as a result from irritants or injury.

5. Emphysema is a condition in which the air sacs in the lungs are damaged and enlarged, resulting in hyperinflation and breathlessness.

6. Progressive airflow limitation occurs, associated with an abnormal inflammatory response of the lungs that is not completely reversible.

7. Chronic obstructive pulmonary disease (COPD) leads to pulmonary insufficiency, pulmonary hypertension, and cor pulmonale.

B. Assessment

1. Cough
2. Exertional dyspnea
3. Wheezing and crackles
4. Sputum production
5. Weight loss
6. Barrel chest (emphysema) (Fig. 50-4)
7. Use of accessory muscles for breathing
8. Prolonged expiration
9. Orthopnea
10. Cardiac dysrhythmias
11. Congestion and hyperinflation seen on chest x-ray (Fig. 50-5)
12. ABG levels that indicate respiratory acidosis and hypoxemia
13. Pulmonary function tests that demonstrate decreased vital capacity

C. Interventions

1. Monitor vital signs.
2. Administer a concentration of oxygen based on ABG values and oxygen saturation by pulse oximetry as prescribed.
3. Monitor pulse oximetry.
4. Provide respiratory treatments and CPT.
5. Instruct the client in diaphragmatic or abdominal breathing techniques, tripod positioning, and pursed-lip breathing techniques, which increase airway pressure and keep air passages open, promoting maximal carbon dioxide expiration.
6. Record the color, amount, and consistency of sputum.
7. Suction the client’s lungs, if necessary, to clear the airway and prevent infection.
8. Monitor weight.
9. Encourage small, frequent meals to maintain nutrition and prevent dyspnea.
10. Provide a high-calorie, high-protein diet with supplements.
11. Encourage fluid intake up to 3000 mL/day to keep secretions thin, unless contraindicated.
12. Place the client in a Fowler’s position and leaning forward to aid in breathing (Fig. 50-6).
13. Allow activity as tolerated.
14. Administer bronchodilators as prescribed, and instruct the client in the use of oral and inhalant medications.
15. Administer corticosteroids as prescribed for exacerbations.
16. Administer mucolytics as prescribed to thin secretions.
17. Administer antibiotics for infection if prescribed.

D. Client education (Box 50-7)

IX. Pneumonia
A. Description
1. Infection of the pulmonary tissue, including the interstitial spaces, the alveoli, and the bronchioles
2. The edema associated with inflammation stiffens the lung, decreases lung compliance and vital capacity, and causes hypoxemia.
3. Pneumonia can be community-acquired or hospital-acquired.
4. The chest x-ray film shows lobar or segmental consolidation, pulmonary infiltrates, or pleural effusions.
5. A sputum culture identifies the organism.
6. The white blood cell count and the erythrocyte sedimentation rate are elevated.

B. Assessment
1. Chills
2. Elevated temperature
3. Pleuritic pain
4. Tachypnea
5. Rhonchi and wheezes
6. Use of accessory muscles for breathing
7. Mental status changes
8. Sputum production
C. Interventions

1. Administer oxygen as prescribed.
3. Monitor for labored respirations, cyanosis, and cold and clammy skin.
4. Encourage coughing and deep breathing and use of the incentive spirometer.
5. Place the client in a semi-Fowler’s position to facilitate breathing and lung expansion.
6. Change the client’s position frequently and ambulate as tolerated to mobilize secretions.
7. Provide CPT (see Chapter 69).
8. Perform nasotracheal suctioning if the client is unable to clear secretions.
10. Monitor and record color, consistency, and amount of sputum.
11. Provide a high-calorie, high-protein diet with small frequent meals.
12. Encourage fluids, up to 3 L/day, to thin secretions unless contraindicated.
13. Provide a balance of rest and activity, increasing activity gradually.
15. Administer antipyretics, bronchodilators, cough suppressants, mucolytic agents, and expectorants as prescribed.
16. Prevent the spread of infection by hand washing and the proper disposal of secretions.

D. Client education

1. About the importance of rest, proper nutrition, and adequate fluid intake
2. To avoid chilling and exposure to individuals with respiratory infections or viruses
3. Regarding medications and the use of inhalants as prescribed
4. To notify the PHCP if chills, fever, dyspnea, hemoptysis, or increased fatigue occurs
5. To receive a pneumococcal vaccine as recommended by the PHCP; refer to the following Web site for information about this vaccine:

Teach clients that using proper hand-washing techniques, disposing of respiratory secretions properly, and receiving vaccines will assist in preventing the spread of infection.

X. Influenza

A. Description

1. Also known as the flu; highly contagious acute viral respiratory infection
2. May be caused by several viruses, usually known as types A, B, and C
3. Yearly vaccination is recommended to prevent the disease, especially for those older than 50 years of age, individuals with chronic illness or who are immunocompromised, those living in institutions, and health care personnel providing direct care to clients (the vaccination is contraindicated in the individual with egg allergies).
4. Additional prevention measures include avoiding those who have developed influenza, frequent and proper hand washing, and cleaning and disinfecting surfaces that have become contaminated with secretions.
5. Avian influenza A (H5N1)
   a. Affects birds; does not usually affect humans; however, human cases have been reported in some countries.
   b. An H5N1 vaccine has been developed for use if a pandemic virus were to emerge.
   c. Reported symptoms are similar to those associated with influenza types A, B, and C.
   d. Prevention measures include thorough cooking of poultry products, avoiding contact with wild animals, frequent and proper hand washing, and cleaning and disinfecting surfaces that have become contaminated with secretions.
6. Swine (H1N1) influenza
   a. A strain of flu that consists of genetic materials from swine, avian, and human influenza viruses
b. Signs and symptoms are similar to those that present with seasonal flu; in addition, vomiting and diarrhea commonly occur.
c. Prevention measures and treatment are the same as for the seasonal flu.

B. Refer to Chapter 18 for information on vaccines.
C. Assessment
   1. Acute onset of fever and muscle aches
   2. Headache
   3. Fatigue, weakness, anorexia
   4. Sore throat, cough, and rhinorrhea

D. Interventions
   1. Encourage rest.
   2. Encourage fluids to prevent pulmonary complications (unless contraindicated).
   4. Provide supportive therapy such as antipyretics or antitussives as indicated.
   5. Administer antiviral medications as prescribed for the current strain of influenza (see Chapter 51).

XI. Legionnaire’s Disease
A. Description
   1. Acute bacterial infection caused by Legionella pneumophila
   2. Sources of the organism include contaminated cooling tower water and warm stagnant water supplies, including water vaporizers, water sonicators, whirlpool spas, and showers.
   3. Person-to-person contact does not occur; the risk for infection is increased by the presence of other conditions.

B. Assessment: Influenza-like symptoms with a high fever, chills, muscle aches, and headache that may progress to dry cough, pleurisy, and sometimes diarrhea
C. Interventions: Treatment is supportive and antibiotics may be prescribed.

XII. Pleural Effusion
A. Description
   1. Pleural effusion is the collection of fluid in the pleural space.
   2. Any condition that interferes with secretion or drainage of this fluid will lead to pleural effusion.

B. Assessment
   1. Pleuritic pain that is sharp and increases with
inspiration
2. Progressive dyspnea with decreased movement of the chest wall on the affected side
3. Dry, nonproductive cough caused by bronchial irritation or mediastinal shift
4. Tachycardia
5. Elevated temperature
6. Decreased breath sounds over affected area
7. Chest x-ray film that shows pleural effusion and a mediastinal shift away from the fluid if the effusion is more than 250 mL

C. Interventions
1. Identify and treat the underlying cause.
2. Monitor breath sounds.
3. Place the client in a Fowler’s position.
4. Encourage coughing and deep breathing.
5. Prepare the client for thoracentesis.
6. If pleural effusion is recurrent, prepare the client for pleurectomy or pleurodesis as prescribed.

D. Pleurectomy
1. Consists of surgically stripping the parietal pleura away from the visceral pleura
2. This produces an intense inflammatory reaction that promotes adhesion formation between the 2 layers during healing.

E. Pleurodesis
1. Involves the instillation of a sclerosing substance into the pleural space via a thoracotomy tube
2. The substance creates an inflammatory response that scleroses tissue together.

XIII. Empyema
A. Description
1. Collection of pus within the pleural cavity
2. The fluid is thick, opaque, and foul-smelling.
3. The most common cause is pulmonary infection and lung abscess caused by thoracic surgery or chest trauma, in which bacteria are introduced directly into the pleural space.
4. Treatment focuses on treating the infection, emptying the empyema cavity, re-expanding the lung, and controlling the infection.

B. Assessment
1. Recent febrile illness or trauma
2. Chest pain

1587
3. Cough
4. Dyspnea
5. Anorexia and weight loss
6. Malaise
7. Elevated temperature and chills
8. Night sweats
9. Pleural exudate on chest x-ray

C. Interventions
1. Monitor breath sounds.
2. Place the client in a semi-Fowler’s or high-Fowler’s position.
3. Encourage coughing and deep breathing.
4. Administer antibiotics as prescribed.
5. Instruct the client to splint the chest as necessary.
6. Assist with thoracentesis or chest tube insertion to promote drainage and lung expansion.
7. If marked pleural thickening occurs, prepare the client for decortication, if prescribed; this surgical procedure involves removal of the restrictive mass of fibrin and inflammatory cells.

XIV. Pleurisy
A. Description
1. Inflammation of the visceral and parietal membranes; may be caused by pulmonary infarction or pneumonia.
2. The visceral and parietal membranes rub together during respiration and cause pain.
3. Pleurisy usually occurs on 1 side of the chest, usually in the lower lateral portions in the chest wall.

B. Assessment
1. Knife-like pain aggravated on deep breathing and coughing
2. Dyspnea
3. Pleural friction rub heard on auscultation

C. Interventions
1. Identify and treat the cause.
3. Administer analgesics as prescribed.
4. Apply hot or cold applications as prescribed.
5. Encourage coughing and deep breathing.
6. Instruct the client to lie on the affected side to splint the chest.
XV. Pulmonary Embolism

A. Description
1. Occurs when a thrombus forms (most commonly in a deep vein), detaches, travels to the right side of the heart, and then lodges in a branch of the pulmonary artery.
2. Clients prone to pulmonary embolism are those at risk for deep vein thrombosis, including those with prolonged immobilization, surgery, obesity, pregnancy, heart failure, advanced age, or a history of thromboembolism.
3. Fat emboli can occur as a complication following fracture of a long bone and can cause pulmonary emboli.
4. Treatment is aimed at prevention through risk factor recognition and elimination.

B. Assessment (Box 50-8)
C. Interventions (see Priority Nursing Actions)

Priority Nursing Actions

Suspected Pulmonary Embolism
1. Notify the Rapid Response Team and primary health care provider (PHCP).
2. Reassure the client and elevate the head of the bed.
3. Prepare to administer the oxygen.
4. Obtain vital signs and check lung sounds.
5. Prepare to obtain an arterial blood gas.
6. Prepare for the administration of heparin therapy or other therapies.

Reference

XVI. Lung Cancer and Laryngeal Cancer: See Chapter 44 for more information
XVII. Carbon Monoxide Poisoning: See Chapter 42 for more information
XVIII. Histoplasmosis

A. Description
1. Pulmonary fungal infection caused by spores of Histoplasma capsulatum
2. Transmission occurs by the inhalation of spores, which commonly are found in contaminated soil.
3. Spores also are usually found in bird droppings.

B. Assessment
1. Similar to pneumonia
2. Positive skin test for histoplasmosis
3. Positive agglutination test
4. Splenomegaly, hepatomegaly

C. Interventions
1. Administer oxygen as prescribed.
2. Monitor breath sounds.
3. Administer antiemetics, antihistamines, antipyretics, and corticosteroids as prescribed.
4. Administer fungicidal medications as prescribed.
5. Encourage coughing and deep breathing.
6. Place the client in a semi-Fowler’s position.
7. Monitor vital signs.
8. Monitor for nephrotoxicity from fungicidal medications.
9. Instruct the client to wear a mask and spray the floor with water before sweeping barn and chicken coops.

XIX. Sarcoidosis
A. Description
1. Presence of epithelioid cell tubercles in the lung
2. The cause is unknown, but a high titer of Epstein-Barr virus may be noted.
3. Viral incidence is highest in African Americans and young adults.

B. Assessment
1. Night sweats
2. Fever
3. Weight loss
4. Cough and dyspnea
5. Skin nodules
6. Polyarthritis
7. Kveim test: Sarcoid node antigen is injected intradermally and causes a local nodular lesion in about 1 month.

C. Interventions
1. Administer corticosteroids to control symptoms.
3. Increase fluid intake.
4. Provide frequent periods of rest.
5. Encourage small, frequent, nutritious meals.

XX. Occupational Lung Disease
A. Description
1. Caused by exposure to environmental or occupational fumes, dust, vapors, gases, bacterial or fungal
antigens, and allergens; can result in acute reversible effects or chronic lung disease.

2. Common disease classifications include occupational asthma pneumoconiosis (silicosis or coal miner’s [black lung] disease), diffuse interstitial fibrosis (asbestosis, talcosis, berylliosis), or extrinsic allergic alveolitis (farmer’s lung, bird fancier’s lung, or machine operator’s lung).

B. Assessment: Manifestations depend on the type of disease and respiratory symptoms.

C. Interventions

1. Prevention through the use of respiratory protective devices
2. Treatment is based on the symptoms experienced by the client.

XXI. Tuberculosis

A. Description

1. Highly communicable disease caused by *Mycobacterium tuberculosis*
2. *M. tuberculosis* is a nonmotile, nonsporulating, acid-fast rod that secretes niacin; when the bacillus reaches a susceptible site, it multiplies freely.
3. Because *M. tuberculosis* is an aerobic bacterium, it primarily affects the pulmonary system, especially the upper lobes, where the oxygen content is highest, but it also can affect other areas of the body, such as the brain, intestines, peritoneum, kidney, joints, and liver.
4. An exudative response causes a nonspecific pneumonitis and the development of granulomas in the lung tissue.
5. Tuberculosis has an insidious onset, and many clients are not aware of symptoms until the disease is well advanced.
6. Improper or noncompliant use of treatment programs may cause the development of mutations in the tubercle bacilli, resulting in a multidrug-resistant strain of tuberculosis (MDR-TB).
7. The goal of treatment is to prevent transmission, control symptoms, and prevent progression of the disease.

B. Risk factors (Box 50-9)
C. Transmission

1. Via the airborne route by droplet infection
2. When an infected individual coughs, laughs, sneezes, or sings, droplet nuclei containing tuberculosis bacteria enter the air and may be inhaled by others.
3. Identification of those in close contact with the infected individual is important so that they can be tested and treated as necessary.
4. When contacts have been identified, these persons are assessed with a tuberculin skin test and chest x-rays to determine infection with tuberculosis.
5. After the infected individual has received tuberculosis medication for 2 to 3 weeks, the risk of transmission is reduced greatly.

D. Disease progression

1. Droplets enter the lungs, and the bacteria form a tubercle lesion.
2. The defense systems of the body encapsulate the tubercle, leaving a scar.
3. If encapsulation does not occur, bacteria may enter the lymph system, travel to the lymph nodes, and cause an inflammatory response termed granulomatous inflammation.
4. Primary lesions form; the primary lesions may become dormant but can be reactivated and become a secondary infection when re-exposed to the bacterium.
5. In an active phase, tuberculosis can cause necrosis and cavitation in the lesions, leading to rupture, the spread of necrotic tissue, and damage to various parts of the body.

E. Client history

1. Past exposure to tuberculosis
2. Client’s country of origin and travel to foreign countries in which the incidence of tuberculosis is high
3. Recent history of influenza, pneumonia, febrile illness, cough, or foul-smelling sputum production
4. Previous tests for tuberculosis; results of the testing
5. Recent bacillus Calmette-Guérin (BCG) vaccine (a vaccine containing attenuated tubercle bacilli that may be given to persons in foreign countries or to persons traveling to foreign countries to produce increased resistance to tuberculosis)
An individual who has received a BCG vaccine will have a positive tuberculin skin test result and should be evaluated for tuberculosis with a chest x-ray.

F. Clinical manifestations
   1. May be asymptomatic in primary infection
   2. Fatigue
   3. Lethargy
   4. Anorexia
   5. Weight loss
   6. Low-grade fever
   7. Chills
   8. Night sweats
   9. Persistent cough and the production of mucoid and mucopurulent sputum, which is occasionally streaked with blood
   10. Chest tightness and a dull, aching chest pain may accompany the cough.

G. Chest assessment
   1. A physical examination of the chest does not provide conclusive evidence of tuberculosis.
   2. A chest x-ray is not definitive, but the presence of multinodular infiltrates with calcification in the upper lobes suggests tuberculosis.
   3. If the disease is active, caseation and inflammation may be seen on the chest x-ray.
   4. Advanced disease
      a. Dullness with percussion over involved parenchymal areas, bronchial breath sounds, rhonchi, and crackles indicate advanced disease.
      b. Partial obstruction of a bronchus caused by endobronchial disease or compression by lymph nodes may produce localized wheezing and dyspnea.

H. QuantiFERON-TB Gold test
   1. A blood analysis test by an enzyme-linked immunosorbent assay
   2. A sensitive and rapid test (results can be available in 24 hours) that assists in diagnosing the client

I. Sputum cultures
   1. Sputum specimens are obtained for an acid-fast smear.
   2. A sputum culture identifying *M. tuberculosis* confirms
the diagnosis.
3. After medications are started, sputum samples are obtained again to determine the effectiveness of therapy.
4. Most clients have negative cultures after 3 months of treatment.

J. Tuberculin skin test (TST) (Table 50-1)

1. A positive reaction does not mean that active disease is present but indicates previous exposure to tuberculosis or the presence of inactive (dormant) disease.
2. Once the test result is positive, it will be positive in any future tests.
3. Skin test interpretation depends on 2 factors: measurement in millimeters of the induration and the person’s risk of being infected with tuberculosis and progression to disease if infected.
4. Once an individual’s skin test is positive, a chest x-ray is necessary to rule out active tuberculosis or to detect old healed lesions.

K. The hospitalized client

1. The client with active tuberculosis is placed under airborne isolation precautions in a negative-pressure room; to maintain negative pressure, the door of the room must be tightly closed.
2. The room should have at least 6 exchanges of fresh air per hour and should be ventilated to the outside environment, if possible.
3. The nurse wears a particulate respirator (a special individually fitted mask) when caring for the client and a gown when the possibility of clothing contamination exists.
4. Thorough hand washing is required before and after caring for the client.
5. If the client needs to leave the room for a test or procedure, the client is required to wear a surgical mask.
6. Respiratory isolation is discontinued when the client is no longer considered infectious.
7. After the infected individual has received tuberculosis medication for 2 to 3 weeks, the risk of transmission is reduced greatly.

L. Client education (Box 50-10)
Box 50-1

Risk Factors for Respiratory Disorders

- Environmental allergies
- Chest injury
- Crowded living conditions
- Exposure to chemicals and environmental pollutants
- Family history of infectious disease
- Frequent respiratory illnesses
- Geographical residence and travel to foreign countries
- Smoking
- Surgery
- Use of chewing tobacco
- Viral syndromes

FIG. 50-1 Positions for thoracentesis.

Box 50-2

Skin Test Procedure

1. Determine hypersensitivity or previous reactions to skin tests.
2. Use a skin site that is free of excessive body hair, dermatitis, and blemishes.
3. Apply the injection at the upper third of the inner surface of the left arm.
4. Circle and mark the injection test site.
5. Document the date, time, and test site.
6. Advise the client not to scratch the test site to prevent infection and possible abscess formation.
7. Instruct the client to avoid washing the test site.
8. Assess the reaction at the injection site 24 to 72 hours after administration of the test antigen.
9. Assess the test site for the amount of induration (hard swelling) in millimeters and for the presence of erythema and vesiculation (small blister-like elevations).

**Box 50-3**  
**Assessment Findings: Pneumothorax**

- Absent or markedly decreased breath sounds on affected side
- Cyanosis
- Decreased chest expansion unilaterally
- Dyspnea

**FIG. 50-2** Pneumothorax. Air in the pleural space causes the lungs to collapse around the hilus and may push the mediastinal contents (heart and great vessels) toward the other lung.
• Hypotension
• Sharp chest pain
• Subcutaneous emphysema as evidenced by crepitus on palpation
• Sucking sound with open chest wound
• Tachycardia
• Tachypnea
• Tracheal deviation to the unaffected side with tension pneumothorax
Triggers*
- Allergens
- Exercise
- Infection
- Irritants

IgE-mast cell mediated response

Release of mediators from mast cells, eosinophils, macrophages, lymphocytes

Early-phase response
- Bronchial smooth muscle constriction*
- Mucosal edema
- Mucus secretion
- Vascular leakage

Peaks in 30 to 60 minutes

Late-phase response
- Bronchial hyperreactivity
- Infiltration with eosinophils and neutrophils
- Inflammation*

Within 1 to 2 days

Infiltration with monocytes and lymphocytes

- Air trapping
- Hypoxemia
- Obstruction of large and small airways
- Respiratory acidosis
**Box 50-4**  
**Asthma Triggers**

### Environmental Factors
- Animal dander
- Cockroaches
- Dust
- Exhaust fumes
- Fireplaces
- Molds
- Perfumes or other products with aerosol sprays
- Pollen
- Smoke, including cigarette or cigar smoke
- Sudden weather changes

### Physiological Factors
- Gastroesophageal reflux disease (GERD)
- Hormonal changes
- Sinusitis
- Stress
- Viral upper respiratory infection

### Medications
- Acetylsalicylic acid (aspirin)
- β-Adrenergic blockers
- Nonsteroidal antiinflammatory drugs

### Occupational Exposure Factors
- Metal salts
- Wood and vegetable dusts
- Industrial chemicals and plastics
Food Additives

- Sulfites (bisulfites and metabisulfites)
- Beer, wine, dried fruit, shrimp, processed potatoes
- Monosodium glutamate

Box 50-5

Classification of Asthma Severity

Severe Persistent

- Symptoms are continuous.
- Physical activity requires limitations.
- Frequent exacerbations occur.
- Nocturnal symptoms occur frequently.

Moderate Persistent

- Daily symptoms occur.
- Daily use of inhaled short-acting β-agonist is needed.
- Exacerbations affect activity.
- Exacerbations occur at least twice weekly and may last for days.
- Nocturnal symptoms occur more frequently than once weekly.

Mild Persistent

- Symptoms occur more frequently than twice weekly but less often than once daily.
- Exacerbations may affect activity.
- Nocturnal symptoms occur more frequently than twice a month.

Mild Intermittent

- Symptoms occur twice weekly or less.
- Client is asymptomatic between exacerbations.
- Exacerbations are brief (hours to days).
- Intensity of exacerbations varies.
- Nocturnal symptoms occur twice a month or less.
**Box 50-6**

**Nursing Interventions During an Acute Asthma Episode**

- Position the client in a high-Fowler’s position or sitting to aid in breathing.
- Administer oxygen as prescribed.
- Stay with the client to decrease anxiety.
- Administer bronchodilators as prescribed.
- Record the color, amount, and consistency of sputum, if any.
- Administer corticosteroids as prescribed.
- Administer magnesium sulfate as prescribed.
- Auscultate lung sounds before, during, and after treatments.
FIG. 50-4  Typical barrel chest in a client with chronic obstructive pulmonary disease.
FIG. 50-5  Diaphragm shape and lung inflation in the normal client and in the client with chronic obstructive pulmonary disease.

FIG. 50-6  Orthopnea positions that clients with chronic obstructive pulmonary disease can assume to ease the work of breathing.

**Box 50-7**

**Client Education: Chronic Obstructive Pulmonary Disease**

- Adhere to activity limitations, alternating rest periods with activity.
- Avoid eating gas-producing foods, spicy foods, and extremely hot or cold foods.
- Avoid exposure to individuals with infections and avoid crowds.
- Avoid extremes in temperature.
• Avoid fireplaces, pets, feather pillows, and other environmental allergens.
• Avoid powerful odors.
• Meet nutritional requirements.
• Receive immunizations as recommended.
• Recognize the signs and symptoms of respiratory infection and hypoxia.
• Stop smoking.
• Use medications and inhalers as prescribed.
• Use oxygen therapy as prescribed.
• Use pursed-lip and diaphragmatic or abdominal breathing.
• When dusting, use a wet cloth.

**Box 50-8**

**Assessment Findings: Pulmonary Embolism**

• Apprehension and restlessness
• Blood-tinged sputum
• Chest pain
• Cough
• Crackles and wheezes on auscultation
• Cyanosis
• Distended neck veins
• Dyspnea accompanied by anginal and pleuritic pain, exacerbated by inspiration
• Feeling of impending doom
• Hypotension
• Petechiae over the chest and axilla
• Shallow respirations
• Tachypnea and tachycardia

**Box 50-9**

**Risk Factors for Tuberculosis**

• Child younger than 5 years of age
• Drinking unpasteurized milk if the cow is infected with bovine tuberculosis
• Homeless individuals or those from a lower socioeconomic group, minority group, or refugee group
• Individuals in constant, frequent contact with an untreated or undiagnosed individual
• Individuals living in crowded areas, such as long-term care facilities, prisons,
and mental health facilities

▪ Older client
▪ Individuals with malnutrition, infection, immune dysfunction, or human immunodeficiency virus infection; or immunosuppressed as a result of medication therapy
▪ Individuals who abuse alcohol or are intravenous drug users

HIV, Human immunodeficiency virus; TB, tuberculosis.

Box 50-10

Client Education: Tuberculosis

▪ Provide the client and family with information about tuberculosis and allay concerns about the contagious aspect of the infection.
▪ Instruct the client to follow the medication regimen exactly as prescribed and always to have a supply of the medication on hand.
▪ Advise the client that the medication regimen is continued up to 12 months depending on the situation.
▪ Advise the client of the side and adverse effects of the medication and ways of minimizing them to ensure compliance.
▪ Reassure the client that after 2 to 3 weeks of medication therapy, it is unlikely that the client will infect anyone.
▪ Advise the client to resume activities gradually.
▪ Instruct the client about the need for adequate nutrition and a well-balanced diet (foods rich in iron, protein, and vitamin C) to promote healing and to prevent recurrence of the infection.
- Inform the client and family that respiratory isolation is not necessary because family members already have been exposed.
- Instruct the client to cover the mouth and nose when coughing or sneezing and to put used tissues into plastic bags.
- Instruct the client and family about thorough hand washing.
- Inform the client that a sputum culture is needed every 2 to 4 weeks once medication therapy is initiated.
- Inform the client that when the results of 3 sputum cultures are negative, the client is no longer considered infectious and usually can return to former employment.
- Advise the client to avoid excessive exposure to silicone or dust because these substances can cause further lung damage.
- Instruct the client regarding the importance of compliance with treatment, follow-up care, and sputum cultures, as prescribed.

**Practice Questions**

566. The emergency department nurse is assessing a client who has sustained a blunt injury to the chest wall. Which finding indicates the presence of a pneumothorax in this client?

1. A low respiratory rate
2. Diminished breath sounds
3. The presence of a barrel chest
4. A sucking sound at the site of injury

567. The nurse is caring for a client hospitalized with acute exacerbation of chronic obstructive pulmonary disease. Which findings would the nurse expect to note on assessment of this client? **Select all that apply.**

1. A low arterial PCO₂ level
2. A hyperinflated chest noted on the chest x-ray
3. Decreased oxygen saturation with mild exercise
4. A widened diaphragm noted on the chest x-ray
5. Pulmonary function tests that demonstrate increased vital capacity

568. The nurse is preparing a list of home care instructions for a client who has been hospitalized and treated for tuberculosis. Which instructions should the nurse include on the list? **Select all that apply.**

1. Activities should be resumed gradually.
2. Avoid contact with other individuals, except family members, for at least 6 months.
3. A sputum culture is needed every 2 to 4 weeks once medication therapy is initiated.
4. Respiratory isolation is not necessary, because family members already have been exposed.

5. Cover the mouth and nose when coughing or sneezing and put used tissues in plastic bags.

6. When 1 sputum culture is negative, the client is no longer considered infectious and usually can return to former employment.

569. The nurse is caring for a client after a bronchoscopy and biopsy. Which finding, if noted in the client, should be reported immediately to the primary health care provider?
   1. Dry cough
   2. Hematuria
   3. Bronchospasm
   4. Blood-streaked sputum

570. The nurse is assessing the respiratory status of a client who has suffered a fractured rib. The nurse should expect to note which finding?
   1. Slow, deep respirations
   2. Rapid, deep respirations
   3. Paradoxic respirations
   4. Pain, especially with inspiration

571. A client with a chest injury has suffered flail chest. The nurse assesses the client for which most distinctive sign of flail chest?
   1. Cyanosis
   2. Hypotension
   3. Paradoxic chest movement
   4. Dyspnea, especially on exhalation

572. The nurse is assessing a client with multiple trauma who is at risk for developing acute respiratory distress syndrome. The nurse should assess for which earliest sign of acute respiratory distress syndrome?
   1. Bilateral wheezing
   2. Inspiratory crackles
   3. Intercostal retractions
   4. Increased respiratory rate

573. The nurse has conducted discharge teaching with a client diagnosed with tuberculosis who has been receiving medication for 2 weeks. The nurse determines that the client has understood the information if the client makes which statement?
   1. “I need to continue medication therapy for 1 month.”
   2. “I can’t shop at the mall for the next 6 months.”
   3. “I can return to work if a sputum culture comes back negative.”
   4. “I should not be contagious after 2 to 3 weeks of medication therapy.”

574. The nurse is preparing to give a bed bath to an immobilized client with tuberculosis. The nurse should wear which items when performing this care?
   1. Surgical mask and gloves
   2. Particulate respirator, gown, and gloves
3. Particulate respirator and protective eyewear
4. Surgical mask, gown, and protective eyewear

575. A client has experienced pulmonary embolism. The nurse should assess for which symptom, which is most commonly reported?
   1. Hot, flushed feeling
   2. Sudden chills and fever
   3. Chest pain that occurs suddenly
   4. Dyspnea when deep breaths are taken

576. A client who is human immunodeficiency virus (HIV)–positive has had a tuberculin skin test (TST). The nurse notes a 7-mm area of induration at the site of the skin test and interprets the result as which finding?
   1. Positive
   2. Negative
   3. Inconclusive
   4. Need for repeat testing

577. A client with acquired immunodeficiency syndrome (AIDS) has histoplasmosis. The nurse should assess the client for which expected finding?
   1. Dyspnea
   2. Headache
   3. Weight gain
   4. Hypothermia

578. The nurse provides discharge instructions to a client with pulmonary sarcoidosis. The nurse concludes that the client understands the information if the client indicates to report which early sign of exacerbation?
   1. Fever
   2. Fatigue
   3. Weight loss
   4. Shortness of breath

579. The nurse is taking the history of a client with occupational lung disease (silicosis). The nurse should assess whether the client wears which item during periods of exposure to silica particles?
   1. Mask
   2. Gown
   3. Gloves
   4. Eye protection

580. The nurse is instructing a hospitalized client with a diagnosis of emphysema about measures that will enhance the effectiveness of breathing during dyspneic periods. Which position should the nurse instruct the client to assume?
   1. Sitting up in bed
   2. Side-lying in bed
   3. Sitting in a recliner chair
   4. Sitting up and leaning on an overbed table

581. The community health nurse is conducting an educational session with community members regarding the signs and symptoms associated with tuberculosis. The nurse informs the participants that tuberculosis is considered as a diagnosis if which signs and symptoms are present? Select
all that apply.

☐ 1. Dyspnea
☐ 2. Headache
☐ 3. Night sweats
☐ 4. A bloody, productive cough
☐ 5. A cough with the expectoration of mucoid sputum

582. The nurse performs an admission assessment on a client with a diagnosis of tuberculosis. The nurse should check the results of which diagnostic test that will confirm this diagnosis?

1. Chest x-ray
2. Bronchoscopy
3. Sputum culture
4. Tuberculin skin test

Answers

566. Answer: 2

Rationale: This client has sustained a blunt or closed-chest injury. Basic symptoms of a closed pneumothorax are shortness of breath and chest pain. A larger pneumothorax may cause tachypnea, cyanosis, diminished breath sounds, and subcutaneous emphysema. Hyper-resonance also may occur on the affected side. A sucking sound at the site of injury would be noted with an open chest injury.

Test-Taking Strategy: Focus on the subject, a blunt chest injury. Noting the word blunt will assist in eliminating option 4, which describes a sucking chest wound injury. Knowing that in a respiratory injury increased respirations will occur will assist you in eliminating option 1. Option 3 can be eliminated because a barrel chest is a characteristic finding in a client with chronic obstructive pulmonary disease.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Respiratory
Health Problem: Adult Health: Respiratory: Chest Injuries
Priority Concepts: Gas Exchange; Perfusion
Reference: Lewis et al. (2017), pp. 519-520.

567. Answer: 2, 3

Rationale: Clinical manifestations of chronic obstructive pulmonary disease (COPD) include hypoxemia, hypercapnia, dyspnea on exertion and at rest, oxygen desaturation with exercise, and the use of accessory muscles of respiration. Chest x-rays reveal a hyperinflated chest and a flattened diaphragm if the disease is advanced. Pulmonary function tests will demonstrate decreased vital capacity.
**Test-Taking Strategy:** Focus on the **subject**, manifestations of COPD. Think about the pathophysiology associated with this disorder. Remember that hypercapnia, a hyperinflated chest, a flat diaphragm, oxygen desaturation on exercise, and decreased vital capacity are manifestations.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Respiratory

**Health Problem:** Adult Health: Respiratory: Obstructive Pulmonary Disease

**Priority Concepts:** Gas Exchange; Perfusion

568. **Answer:** 1, 3, 4, 5

**Rationale:** The nurse should provide the client and family with information about tuberculosis and allay concerns about the contagious aspect of the infection. The client needs to follow the medication regimen exactly as prescribed and always have a supply of the medication on hand. Side and adverse effects of the medication and ways of minimizing them to ensure compliance should be explained. After 2 to 3 weeks of medication therapy, it is unlikely that the client will infect anyone. Activities should be resumed gradually and a well-balanced diet that is rich in iron, protein, and vitamin C to promote healing and prevent recurrence of infection should be consumed. Respiratory isolation is not necessary, because family members already have been exposed. Instruct the client about thorough hand washing, to cover the mouth and nose when coughing or sneezing, and to put used tissues into plastic bags. A sputum culture is needed every 2 to 4 weeks once medication therapy is initiated. When the results of 3 sputum cultures are negative, the client is no longer considered infectious and can usually return to former employment.

**Test-Taking Strategy:** Focus on the **subject**, home care instructions for tuberculosis. Knowledge regarding the pathophysiology, transmission, and treatment of tuberculosis is needed to answer this question. Read each option carefully to answer correctly.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Teaching and Learning

**Content Area:** Adult Health: Respiratory

**Health Problem:** Adult Health: Respiratory: Tuberculosis

**Priority Concepts:** Client Education; Infection

569. **Answer:** 3

**Rationale:** If a biopsy was performed during a bronchoscopy, blood-streaked sputum is expected for several hours. Frank blood indicates hemorrhage. A dry cough may be expected. The client should be assessed for signs of complications, which would include cyanosis, dyspnea, stridor, bronchospasm, hemoptysis, hypotension, tachycardia, and dysrhythmias. Hematuria is unrelated to this
procedure.

**Test-Taking Strategy:** Note the **strategic word**, *immediately*. Eliminate option 2 first because it is unrelated to the procedure. Next, eliminate option 1, because a dry cough may be expected. Noting that a biopsy has been performed will assist in eliminating option 4, because blood-streaked sputum would be expected. Note that the correct option relates to the airway.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Complex Care: Emergency Situations/Management

**Health Problem:** N/A

**Priority Concepts:** Clinical Judgment; Gas Exchange

570. **Answer:** 4

**Rationale:** Rib fractures result from a blunt injury or a fall. Typical signs and symptoms include pain and tenderness localized at the fracture site that is exacerbated by inspiration and palpation, shallow respirations, splinting or guarding the chest protectively to minimize chest movement, and possible bruising at the fracture site. Paradoxical respirations are seen with flail chest.

**Test-Taking Strategy:** Focus on the **subject**, findings associated with a rib fracture. Focusing on the anatomical location of the injury will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Respiratory

**Health Problem:** Adult Health: Respiratory: Chest Injuries

**Priority Concepts:** Gas Exchange; Pain

**Reference:** Lewis et al. (2017), p. 521.

571. **Answer:** 3

**Rationale:** Flail chest results from multiple rib fractures. This results in a “floating” section of ribs. Because this section is unattached to the rest of the bony rib cage, this segment results in paradoxical chest movement. This means that the force of inspiration pulls the fractured segment inward, while the rest of the chest expands. Similarly, during exhalation, the segment balloons outward while the rest of the chest moves inward. This is a characteristic sign of flail chest.

**Test-Taking Strategy:** Note the **strategic word**, *most*. Cyanosis and hypotension occur with many different disorders, so eliminate options 1 and 2 first. From the remaining options, choose paradoxical chest movement over dyspnea on exhalation by remembering that a flail chest has broken rib segments that move independently of the rest of the rib cage.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity
**Integrated Process:** Nursing Process—Assessment
**Content Area:** Adult Health: Respiratory
**Health Problem:** Adult Health: Respiratory: Chest Injuries
**Priority Concepts:** Gas Exchange; Pain
**Reference:** Lewis et al. (2017), pp. 521-522.

572. **Answer:** 4

**Rationale:** The earliest detectable sign of acute respiratory distress syndrome is an increased respiratory rate, which can begin from 1 to 96 hours after the initial insult to the body. This is followed by increasing dyspnea, air hunger, retraction of accessory muscles, and cyanosis. Breath sounds may be clear or consist of fine inspiratory crackles or diffuse coarse crackles.

**Test-Taking Strategy:** Note the **strategic word**, *earliest*. Eliminate option 3 first, because intercostal retraction is a later sign of respiratory distress. Of the remaining options, recall that adventitious breath sounds (options 1 and 2) would occur later than an increased respiratory rate.

**Level of Cognitive Ability:** Analyzing
**Client Needs:** Physiological Integrity
**Integrated Process:** Nursing Process—Assessment
**Content Area:** Adult Health: Respiratory
**Health Problem:** Adult Health: Respiratory: Acute Respiratory Distress Syndrome/Failure
**Priority Concepts:** Gas Exchange; Perfusion
**Reference:** Lewis et al. (2017), pp. 1622-1623.

573. **Answer:** 4

**Rationale:** The client is continued on medication therapy for up to 12 months, depending on the situation. The client generally is considered noncontagious after 2 to 3 weeks of medication therapy. The client is instructed to wear a mask if there will be exposure to crowds until the medication is effective in preventing transmission. The client is allowed to return to work when the results of 3 sputum cultures are negative.

**Test-Taking Strategy:** Focus on the **subject**, client understanding of medication therapy. Knowing that the medication therapy lasts for up to 12 months helps you eliminate option 1 first. Knowing that 3 sputum cultures must be negative helps you eliminate option 3 next. From the remaining options, recalling that the client is not contagious after 2 to 3 weeks of therapy will direct you to the correct option.

**Level of Cognitive Ability:** Evaluating
**Client Needs:** Physiological Integrity
**Integrated Process:** Nursing Process—Evaluation
**Content Area:** Adult Health: Respiratory
**Health Problem:** Adult Health: Respiratory: Tuberculosis
**Priority Concepts:** Client Education; Infection
574. **Answer:** 2

**Rationale:** The nurse who is in contact with a client with tuberculosis should wear an individually fitted particulate respirator. The nurse also would wear gloves as per standard precautions. The nurse wears a gown when the possibility exists that the clothing could become contaminated, such as when giving a bed bath.

**Test-Taking Strategy:** Focus on the **subject**, precautions when caring for the client with tuberculosis. Think about the nurse’s task, a bed bath. Knowing that the nurse should wear a particulate respirator eliminates options 1 and 4. Knowledge of basic standard precautions directs you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Foundations of Care: Infection Control

**Health Problem:** Adult Health: Respiratory: Tuberculosis

**Priority Concepts:** Infection; Safety

575. **Answer:** 3

**Rationale:** The most common initial symptom in pulmonary embolism is chest pain that is sudden in onset. The next most commonly reported symptom is dyspnea, which is accompanied by an increased respiratory rate. Other typical symptoms of pulmonary embolism include apprehension and restlessness, tachycardia, cough, and cyanosis.

**Test-Taking Strategy:** Note the **strategic word**, most. Because pulmonary embolism does not result from an infectious process or an allergic reaction, eliminate options 1 and 2 first. To select between the correct option and option 4, look at them closely. Option 4 states dyspnea when deep breaths are taken. Although dyspnea commonly occurs with pulmonary embolism, dyspnea is not associated only with deep breathing. Therefore, eliminate option 4.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Respiratory

**Health Problem:** Adult Health: Respiratory: Pulmonary Embolism

**Priority Concepts:** Gas Exchange; Perfusion

576. **Answer:** 1

**Rationale:** The client with HIV infection is considered to have positive results on tuberculin skin testing with an area of induration larger than 5 mm. The client without HIV is positive with an induration larger than 10 mm. The client with HIV is immunosuppressed, making a smaller area of induration positive for this type of client. It is possible for the client infected with HIV to have false-negative readings because of the immunosuppression factor. Options 2, 3, and 4 are incorrect.
interpretations.

**Test-Taking Strategy:** Eliminate options 3 and 4 first because they are **comparable or alike.** From the remaining options, recalling that the client with HIV infection is immunosuppressed will assist in determining the interpretation of the area of induration.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Analysis

**Content Area:** Adult Health: Respiratory

**Health Problem:** Adult Health: Respiratory: Tuberculosis

**Priority Concepts:** Evidence; Infection

577. **Answer:** 1

**Rationale:** Histoplasmosis is an opportunistic fungal infection that can occur in the client with AIDS. The infection begins as a respiratory infection and can progress to disseminated infection. Typical signs and symptoms include fever, dyspnea, cough, and weight loss. Enlargement of the client’s lymph nodes, liver, and spleen may occur as well.

**Test-Taking Strategy:** Focus on the **subject,** manifestations of histoplasmosis. Recalling that histoplasmosis is an infectious process will help you eliminate option 4. Because the client has AIDS and another infection, weight gain is an unlikely symptom and can be eliminated next. Knowing that histoplasmosis begins as a respiratory infection helps you choose dyspnea over headache as the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Respiratory

**Health Problem:** Adult Health: Respiratory: Viral, bacterial, fungal infections

**Priority Concepts:** Clinical Judgment; Infection

578. **Answer:** 4

**Rationale:** Dry cough and dyspnea are typical early manifestations of pulmonary sarcoidosis. Later manifestations include night sweats, fever, weight loss, and skin nodules.

**Test-Taking Strategy:** Note the **strategic word,** early. Because sarcoidosis is a pulmonary problem, eliminate options 1 and 3 first. Select the correct option over option 2 because the shortness of breath (and impaired ventilation) appears first and would cause the fatigue as a secondary symptom.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Evaluation

**Content Area:** Adult Health: Respiratory

**Health Problem:** Adult Health: Respiratory: Environmental

1614
**Priority Concepts:** Client Education; Gas Exchange  
**Reference:** Lewis et al. (2017), pp. 528-529.

579. **Answer:** 1

**Rationale:** Silicosis results from chronic, excessive inhalation of particles of free crystalline silica dust. The client should wear a mask to limit inhalation of this substance, which can cause restrictive lung disease after years of exposure. Options 2, 3, and 4 are not necessary.  
**Test-Taking Strategy:** Focus on the **subject**, prevention of silicosis. Recalling that exposure to silica dust causes the illness and that the dust is inhaled into the respiratory tract will direct you to the correct option.  
**Level of Cognitive Ability:** Applying  
**Client Needs:** Safe and Effective Care Environment

**Content Area:** Adult Health: Respiratory  
**Health Problem:** Adult Health: Respiratory: Environmental  
**Priority Concepts:** Infection; Safety  
**Reference:** Lewis et al. (2017), p. 513.

580. **Answer:** 4

**Rationale:** Positions that will assist the client with emphysema with breathing include sitting up and leaning on an overbed table, sitting up and resting the elbows on the knees, and standing and leaning against the wall.  
**Test-Taking Strategy:** Eliminate options 1 and 3 first because they are comparable or alike. Next, eliminate option 2 because this position will not enhance breathing.  
**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Respiratory  
**Health Problem:** Adult Health: Respiratory: Obstructive Pulmonary Disease  
**Priority Concepts:** Client Education; Gas Exchange  

581. **Answer:** 1, 3, 4, 5

**Rationale:** Tuberculosis should be considered for any clients with a persistent cough, weight loss, anorexia, night sweats, hemoptysis, shortness of breath, fever, or chills. The client’s previous exposure to tuberculosis should also be assessed and correlated with the clinical manifestations.  
**Test-Taking Strategy:** Note the **subject**, clinical manifestations of tuberculosis. Note that headache is not specifically associated with tuberculosis, is not respiratory in nature, and is not associated with an infection to assist in eliminating this option.  
**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning
Rationale: Tuberculosis is definitively diagnosed through culture and isolation of Mycobacterium tuberculosis. A presumptive diagnosis is made based on a tuberculin skin test, a sputum smear that is positive for acid-fast bacteria, a chest x-ray, and histological evidence of granulomatous disease on biopsy.

Test-Taking Strategy: Focus on the subject, confirming the diagnosis of tuberculosis. Confirmation is made by identifying the bacteria, M. tuberculosis.

CHAPTER 51

Respiratory Medications

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Gas Exchange; Infection

I. Medication Inhalation Devices
   A. Metered-dose inhaler (MDI): Uses a chemical propellant to push the medication out of the inhaler (Fig. 51-1)
   B. Dry powder inhaler (DPI): Delivers medication without using chemical propellants, but it requires strong and fast inhalation.
   C. Nebulizer: Delivers fine liquid mists of medication through a tube or a mask that fits over the nose and mouth, or with a mouthpiece, using air or oxygen under pressure.
   D. If 2 different inhaled medications are prescribed and 1 of the medications contains a glucocorticoid (corticosteroid), administer the bronchodilator first and the corticosteroid second.

   If 2 different inhaled medications are prescribed, instruct the client to wait 5 minutes following administration of the first before inhaling the second. If a second dose of the same medication is needed, instruct the client to wait 1 to 2 minutes before taking the second dose.

II. Bronchodilators (Box 51-1)
   A. Description
      1. Sympathomimetic bronchodilators relax the smooth muscle of the bronchi and dilate the airways of the respiratory tree, making air exchange and respiration easier for the client. Examples include β₂-adrenergic agonists, such as albuterol.
      2. Methylxanthine bronchodilators stimulate the central nervous system (CNS) and respiration, dilate coronary and pulmonary vessels, cause diuresis, and relax smooth muscle. An example is theophylline.
      3. Used to treat acute bronchospasm, acute and chronic asthma, bronchitis, restrictive airway diseases, and reactive airway diseases
4. Contraindicated in individuals with hypersensitivity, peptic ulcer disease, severe cardiac disease and cardiac dysrhythmias, hyperthyroidism, or uncontrolled seizure disorders

5. Used with caution in clients with hypertension, diabetes mellitus, or narrow-angle glaucoma

6. Theophylline increases the risk of digoxin toxicity and decreases the effects of lithium and phenytoin. Theophylline should be a last-line medication.

7. If theophylline and a β₂-adrenergic agonist are administered together, cardiac dysrhythmias may result.

8. Beta blockers, cimetidine, and erythromycin increase the effects of theophylline.

9. Barbiturates and carbamazepine decrease the effects of theophylline.

B. Side and adverse effects

1. Palpitations and tachycardia

2. Dysrhythmias

3. Restlessness, nervousness, tremors

4. Anorexia, nausea, and vomiting

5. Headaches and dizziness

6. Hyperglycemia

7. Mouth dryness and throat irritation with inhalers

8. Tolerance and paradoxical bronchoconstriction with inhalers

C. Interventions

1. Assess lung sounds.

2. Monitor for cardiac dysrhythmias.

3. Assess for cough, wheezing, decreased breath sounds, and sputum production.

4. Monitor for restlessness and confusion.

5. Provide adequate hydration.

6. Administer the medication at regular intervals around the clock to maintain a sustained therapeutic level.

7. Administer oral medications with or after meals to decrease gastrointestinal irritation.

8. Monitor for a therapeutic serum theophylline level of 10 to 20 mcg/mL (55.5 to 111 mcmol/L).

9. Intravenously administered theophylline preparations should be administered slowly and always via an
10. **Client education**

   a. Not to crush enteric-coated or sustained-release tablets or capsules
   b. To avoid caffeine-containing products such as coffee, tea, cola, and chocolate, and over-the-counter medications
   c. About the side and adverse effects of bronchodilators
   d. How to monitor the pulse and to report any abnormalities to the primary health care provider (PHCP)
   e. How to use an inhaler, spacer (see Fig. 51-1), or nebulizer and how to monitor the amount of medication remaining in an inhaler canister
   f. The importance of smoking cessation and information regarding support resources
   g. To monitor blood glucose levels if diabetes mellitus is a coexisting condition
   h. To wear a MedicAlert bracelet, particularly if the client has asthma

**Theophylline toxicity is likely to occur when**
the serum level is higher than 20 mcg/mL (111 mcmol/L). Early signs of toxicity include restlessness, nervousness, tremors, palpitations, and tachycardia.

### III. Anticholinergics (see Box 51-1)

A. Inhaled medications that improve lung function by blocking muscarinic receptors in the bronchi, which prevents bronchoconstriction

B. Effective for treating chronic obstructive pulmonary disease, allergy-induced asthma, and exercise-induced bronchospasm

C. Side effects include dry mouth and irritation of the pharynx; sucking on sugarless candy will help relieve symptoms.

D. Systemic anticholinergic effects rarely occur but can include increased intraocular pressure, blurred vision, tachycardia, cardiovascular events, urinary retention, and constipation.

**The client with a peanut allergy should not take certain ipratropium products because they contain soy lecithin, which is in the same plant family as peanuts.**
IV. Glucocorticoids (Corticosteroids) (see Box 51-1)
   A. Glucocorticoids act as antiinflammatory agents and reduce edema of the airways; they are used to treat asthma and other inflammatory respiratory conditions.
   B. See Chapter 47 for information on glucocorticoids.

V. Leukotriene Modifiers (see Box 51-1)
   A. Description
      1. Used in the prophylaxis and treatment of chronic bronchial asthma (not used for acute asthma episodes)
      2. Inhibit bronchoconstriction caused by specific antigens and reduce airway edema and smooth muscle constriction
      3. Contraindicated in clients with hypersensitivity and in breast-feeding mothers
      4. Should be used with caution in clients with impaired hepatic function
      5. Coadministration of inhaled glucocorticoids increases the risk of upper respiratory infection.
   B. Side and adverse effects
      1. Headache
      2. Nausea and vomiting
      3. Dyspepsia
      4. Diarrhea
      5. Generalized pain, myalgia
      6. Fever
      7. Dizziness
   C. Interventions
      1. Assess frequency of exacerbations.
      2. Assess changes in lung function.
      3. Assess liver function laboratory values.
   D. Client education
      1. To take medication 1 hour before or 2 hours after meals
      2. To increase fluid intake
      3. Not to discontinue the medication and to take it as prescribed, even during symptom-free periods

VI. Inhaled Nonsteroidal Antiallergy Agent (see Box 51-1)
   A. Description
      1. Antiasthmatic, antiallergic, and mast cell stabilizers inhibit mast cell release after exposure to antigens.
      2. Used to treat allergic rhinitis, bronchial asthma, and exercise-induced bronchospasm
      3. Contraindicated in clients with known hypersensitivity
      4. Orally administered cromolyn sodium is used with caution in clients with impaired hepatic or renal
function.

B. Side and adverse effects

1. Cough, sneezing, nasal sting, or bronchospasm following inhalation
2. Unpleasant taste in the mouth

C. Interventions: Monitor respirations and assess lung sounds for rhonchi or wheezing.

D. Client education

1. To administer oral capsules at least 30 minutes before meals
2. Not to discontinue the medication abruptly, because a rebound asthmatic attack can occur

Instruct the client taking inhaled medications to drink a few sips of water before and after inhalation to prevent a cough and an unpleasant taste in the mouth.

VII. Monoclonal Antibody (see Box 51-1)

A. Description

1. Omalizumab is a recombinant DNA-derived humanized immunoglobulin G (IgG) murine monoclonal antibody that selectively binds to immunoglobulin E (IgE) to limit the release of mediators in the allergic response.
2. Used to treat allergy-related asthma; administered subcutaneously every 2 to 4 weeks
3. Dose is titrated on the basis of the serum IgE level and body weight.
4. Contraindicated in those with hypersensitivity to the medication

B. Side and adverse effects

1. Injection site reactions
2. Viral infections
3. Upper respiratory infections
4. Sinusitis
5. Headache
6. Pharyngitis
7. Anaphylaxis
8. Malignancies

C. Interventions

1. Assess respiratory rate, rhythm, and depth, and auscultate lung sounds.
2. Assess for allergies and/or allergic reaction symptoms such as rash or urticaria.
3. Have medications for the treatment of severe hypersensitivity reactions available during initial administration in case anaphylaxis occurs.

D. Client education

1. That respiratory improvement will not be immediate
2. Not to stop taking or decrease the currently prescribed asthma medications unless instructed
3. To avoid receiving live virus vaccines for the duration of treatment

VIII. Antihistamines (Box 51-2)

A. Description

1. Called histamine antagonists or H₁ blockers; these medications compete with histamine for receptor sites, thus preventing a histamine response.
2. When the H₁ receptor is stimulated, the extravascular smooth muscles, including those lining the nasal cavity, are constricted.
3. Decrease nasopharyngeal, gastrointestinal, and bronchial secretions by blocking the H₁ receptor
4. Used for the common cold, rhinitis, nausea and vomiting, motion sickness, urticaria, and as a sleep aid
5. Can cause CNS depression if taken with alcohol, opioids, hypnotics, or barbiturates, particularly with first-generation antihistamines
6. Should be used with caution in clients with chronic obstructive pulmonary disease because of their drying effect
7. Diphenhydramine has an anticholinergic effect and should be avoided in clients with narrow-angle glaucoma.

B. Side and adverse effects

1. Drowsiness and fatigue
2. Dizziness
3. Urinary retention
4. Blurred vision
5. Wheezing
6. Constipation
7. Dry mouth
8. Gastrointestinal irritation
9. Hypotension

1622
10. Hearing disturbances
11. Photosensitivity
12. Nervousness and irritability
13. Confusion
14. Nightmares

C. Interventions
1. Monitor for signs of urinary dysfunction.
2. Administer with food or milk.
3. Avoid subcutaneous injection, and administer by intramuscular injection in a large muscle if the intramuscular route is prescribed.

D. Client education
1. To avoid hazardous activities, alcohol, and other CNS depressants
2. If the medication is being taken for motion sickness, take it 30 minutes before the event and then before meals and at bedtime during the event as prescribed.
3. To suck on hard candy or ice chips for dry mouth

IX. Nasal Decongestants (Box 51-3)
A. Description
1. Nervousness
2. Restlessness, insomnia
3. Hypertension
4. Hyperglycemia

B. Side and adverse effects
1. Include adrenergic, anticholinergic, and corticosteroid medications
2. Shrink nasal mucosal membranes and reduce fluid secretion
3. Used for allergic rhinitis, hay fever, and acute coryza (profuse nasal discharge)
4. Contraindicated or used with extreme caution in clients with hypertension, cardiac disease, hyperthyroidism, or diabetes mellitus

C. Interventions
1. Monitor for cardiac dysrhythmias.
2. Monitor blood glucose levels.

D. Client education

Nasal decongestants can cause tolerance and rebound nasal congestion (vasodilation) caused by irritation of the nasal mucosa. Therefore, the client needs to be
informed that these medications should not be used for longer than 48 hours.
1. To avoid consuming caffeine in large amounts because it can increase restlessness and palpitations
2. About the importance of limiting the use of nasal sprays and drops to prevent rebound nasal congestion; consider weaning off one nare at a time to prevent this.

X. Expectorants and Mucolytic Agents (Box 51-4)
A. Description
1. Expectorants loosen bronchial secretions so that they can be eliminated with coughing; they are used for a dry unproductive cough and to stimulate bronchial secretions.
2. Mucolytic agents thin mucous secretions to help make the cough more productive.
3. Mucolytic agents with dextromethorphan should not be used by clients with chronic obstructive pulmonary disease because they suppress the cough.
4. Acetylcysteine can increase airway resistance and should not be used in clients with asthma. This medication can also be used to prevent liver damage in acetaminophen overdose, as well as to protect the kidneys in the event that diagnostic testing requiring contrast dye is done.

B. Side and adverse effects
1. Gastrointestinal irritation
2. Rash
3. Oropharyngeal irritation

C. Interventions
1. Acetylcysteine, administered by nebulization, should not be mixed with another medication.
2. If acetylcysteine is administered with a bronchodilator, the bronchodilator should be administered 5 minutes before the acetylcysteine.
3. Monitor for side effects of acetylcysteine such as nausea and vomiting, stomatitis, and runny nose.

D. Client education
1. To take the medication with a full glass of water to loosen mucus
2. To maintain adequate fluid intake
3. To cough and deep breathe

XI. Antitussives (Box 51-5)
A. Description: Act on the cough control center in the medulla to suppress the cough reflex; used for a cough that is nonproductive and irritating
B. Side and adverse effects
1. Dizziness, drowsiness, sedation
2. Gastrointestinal irritation, nausea
3. Dry mouth
4. Constipation
5. Respiratory depression

C. Interventions
1. Encourage the client to take adequate fluids with the medication.
2. Encourage the client to sleep with the head of the bed elevated.
3. Note that medication dependency can occur.
4. Avoid administration to the client with a head injury or a postoperative cranial surgery client.
5. Avoid administration to the client using opioids, sedative-hypnotics, barbiturates, or select antidepressants, because CNS depression can occur.

D. Client education
1. If the cough lasts longer than 1 week and a fever or rash occurs, to notify the PHCP
2. To avoid hazardous activities
3. To avoid the use of alcohol

XII. Opioid Antagonists (Box 51-6)

A. Description
1. Reverses respiratory depression in opioid overdose
2. Avoid its use for nonopioid respiratory depression.
3. Reoccurrence of respiratory depression can occur if duration of opiate exceeds duration of opioid antagonist.
4. This medication may be prescribed for clients at risk for opioid overdose.
5. https://www.nsc.org/home-safety/safety-topics/opioids/prescription-nation?gclid=EAIaIQobChMIiJXd446a2wIViYizCh0-adoeayasaaaegfc_d_bwE

B. Side and adverse effects
1. Nausea, vomiting
2. Tremors
3. Sweating
4. Increased blood pressure
5. Tachycardia

C. Interventions
1. Assess vital signs, especially respirations.
2. For intravenous administration, the dose is titrated every 2 to 5 minutes as prescribed.
3. Have oxygen and resuscitative equipment available during administration.

XIII. **Tuberculosis** Medications *(Box 51-7)*

A. Description

1. Offer the most effective method for treating the disease and preventing transmission.
2. Treatment of identified lesions depends on whether the individual has active disease or has only been exposed to the disease.
3. Treatment is difficult because the bacterium has a waxy substance on the capsule that makes penetration and destruction difficult.
4. The use of a multidrug regimen destroys organisms as quickly as possible and minimizes the emergence of drug-resistant organisms.
5. Active tuberculosis is treated with a combination of medications to which the organism is susceptible.
6. Individuals with active tuberculosis are treated for 6 to 9 months; however, clients with immunosuppression (e.g., HIV) are treated for a longer period of time.
7. After the infected individual has received medication for 2 to 3 weeks, the risk of transmission is greatly reduced.
8. Most clients have negative sputum cultures after 3 months of compliance with medication therapy.
9. Individuals who have been exposed to active tuberculosis are treated with preventive isoniazid for 9 to 12 months.

B. First-line or second-line medications

1. First-line medications provide the most effective antituberculosis activity.
2. Second-line medications are used in combination with first-line medications but are more toxic.
3. Current infecting organisms are proving resistant to standard first-line medications; the resistant organisms develop because individuals with the disease fail to complete the course of treatment, so surviving bacteria adapt to the medication and become resistant.
4. Multidrug therapies are instituted because of the resistant organisms.

C. **Multidrug-resistant strain of tuberculosis (MDR-TB)**

1. Resistance occurs when a client receiving 2 medications (first-line and second-line medications) discontinues 1 of the medications.
2. The client briefly experiences some response from the single medication, but then large numbers of resistant organisms begin to grow.
3. The client, infectious again, transmits the drug-resistant organism to other individuals.
4. As this event is repeated, an organism develops that is resistant to many of the first-line tuberculosis medications.

D. General client education points for tuberculosis medications

1. Not to skip doses and to take medication for the full length of the prescribed therapy
2. Not to take any other medication without consulting with the PHCP
3. About the importance of follow-up PHCP visits and laboratory tests
4. To avoid alcohol
5. To take medication on an empty stomach with 8 oz of water 1 hour before or 2 hours after meals and to avoid taking antacids with the medication
6. About the adverse effects that require PHCP notification
7. Inform the client about direct observed therapy (DOT) to ensure adherence to the medication regimen.

XIV. First-Line Medications for Tuberculosis (see Box 51-7)

A. Isoniazid

1. Description
   a. Bactericidal
   b. Inhibits the synthesis of mycolic acids and acts to kill actively growing organisms in the extracellular environment
   c. Inhibits the growth of dormant organisms in the macrophages and caseating granulomas
   d. Is active only during cell division and is used in combination with other antitubercular medications

2. **Contraindications and cautions**
   a. Contraindicated in clients with
hypersensitivity or with acute liver disease
b. Use with caution in clients with chronic liver disease, alcoholism, or renal impairment.
c. Use with caution in clients taking nicotinic acid.
d. Use with caution in clients taking hepatotoxic medications because the risk for hepatotoxicity increases.
e. Alcohol increases the risk of hepatotoxicity.
f. May increase the risk of toxicity of carbamazepine and phenytoin
g. May decrease ketoconazole concentrations

3. Side and adverse effects
a. Hypersensitivity reactions
b. Peripheral neuritis
c. Neurotoxicity
d. Hepatotoxicity and hepatitis; increased liver function test levels
e. Pyridoxine deficiency
f. Irritation at injection site with intramuscular administration
g. Nausea and vomiting
h. Dry mouth
i. Dizziness
j. Hyperglycemia
k. Vision changes

4. Interventions
a. Assess for hypersensitivity.
b. Assess for hepatic dysfunction.
c. Assess for sensitivity to nicotinic acid.
d. Monitor liver function test results.
e. Monitor for signs of hepatitis, such as anorexia, nausea, vomiting, weakness, fatigue, dark urine, or jaundice; if these symptoms occur, withhold the medication and notify the PHCP.
f. Monitor for tingling, numbness, or burning of the extremities.
g. Assess mental status.
h. Monitor for visual changes, and notify the PHCP if they occur.
i. Assess for dizziness and initiate safety precautions.
j. Monitor complete blood count (CBC) and blood glucose levels.
k. Administer isoniazid 1 hour before or 2 hours after a meal, because food may delay absorption.
l. Administer isoniazid at least 1 hour before antacids.
m. Administer pyridoxine as prescribed to reduce the risk of neurotoxicity.

Many tuberculosis medications can cause toxic effects such as hepatotoxicity, nephrotoxicity, neurotoxicity, optic neuritis, or ototoxicity. Teach the client about the signs of toxicity and inform the client that the PHCP needs to be notified if any signs arise.

5. Client education

a. To avoid tyramine-containing foods because they may cause a reaction such as red and itching skin, a pounding heartbeat, lightheadedness, a hot or clammy feeling, or a headache; if this occurs, the client should notify the PHCP.
b. To recognize the signs of neurotoxicity, hepatitis, and hepatotoxicity
c. To notify the PHCP if signs of neurotoxicity, hepatitis and hepatotoxicity, or visual changes occur.

B. Rifampin

1. Description

a. Inhibits bacterial RNA synthesis
b. Binds to DNA-dependent RNA polymerase and blocks RNA transcription
c. Used with at least 1 other antitubercular medication
2. Contraindications and cautions
   a. Contraindicated in clients with hypersensitivity
   b. Used with caution in clients with hepatic dysfunction or alcoholism
   c. Use of alcohol or hepatotoxic medications may increase the risk of hepatotoxicity.
   d. Decreases the effects of several medications, including oral anticoagulants, oral hypoglycemics, chloramphenicol, digoxin, disopyramide phosphate, mexiletine, quinidine polygalacturonate, fluconazole, methadone hydrochloride, phenytoin, and verapamil hydrochloride

3. Side and adverse effects
   a. Hypersensitivity reaction, including fever, chills, shivering, headache, muscle and bone pain, and dyspnea
   b. Heartburn, nausea, vomiting, diarrhea
   c. Red-orange–colored body secretions
   d. Vision changes
   e. Hepatotoxicity and hepatitis
   f. Increased uric acid levels
   g. Blood dyscrasias
   h. Colitis

4. Interventions
   a. Assess for hypersensitivity.
   b. Evaluate CBC, uric acid, and liver function test results.
   c. Assess for signs of hepatitis; if they occur, withhold the medication and notify the PHCP.
   d. Monitor for signs of colitis.
   e. Assess for visual changes.

5. Client education
   a. That urine, feces, sweat, and tears will be red-orange and that soft contact lens
can become permanently discolored
b. To notify the PHCP if jaundice (yellow eyes or skin) develops or if weakness, fatigue, nausea, vomiting, sore throat, fever, or unusual bleeding occurs

C. Ethambutol

1. Description
   a. Bacteriostatic
   b. Interferes with cell metabolism and multiplication by inhibiting 1 or more metabolites in susceptible organisms
   c. Inhibits bacterial RNA synthesis and is active only during cell division
   d. Slow-acting and must be used with other bactericidal agents

2. Contraindications and cautions
   a. Contraindicated in clients with hypersensitivity or optic neuritis and in children younger than 13 years
   b. Used with caution in clients with renal dysfunction, gout, ocular defects, diabetic retinopathy, cataracts, or ocular inflammatory conditions
   c. Used with caution in clients taking neurotoxic medications because the risk for neurotoxicity increases

3. Side and adverse effects
   a. Hypersensitivity reactions
   b. Anorexia, nausea, vomiting
   c. Dizziness
   d. Malaise
   e. Mental confusion
   f. Joint pain
   g. Dermatitis
   h. Optic neuritis
   i. Peripheral neuritis
   j. Thrombocytopenia
   k. Increased uric acid levels
   l. Anaphylactoid reaction

4. Interventions
   a. Assess the client for hypersensitivity.
   b. Evaluate results of CBC, uric acid, and renal and liver function tests.
c. Monitor for visual changes such as altered color perception and decreased visual acuity; if changes occur, withhold the medication and notify the PHCP.
d. Administer once every 24 hours and administer with food to decrease gastrointestinal upset.
e. Monitor uric acid concentration and assess for painful or swollen joints or signs of gout.
f. Monitor intake and output and for adequate renal function.
g. Assess mental status.
h. Monitor for dizziness and initiate safety precautions.
i. Assess for peripheral neuritis (numbness, tingling, or burning of the extremities); if it occurs, notify the PHCP.

5. Client education

a. That nausea, related to the medication, can be prevented by taking the daily dose at bedtime or by taking the prescribed antinausea medications
b. To notify the PHCP immediately if any visual problems occur or if a rash; swelling and pain in the joints; or numbness, tingling, or burning in the hands or feet occurs

D. Pyrazinamide

1. Description

a. The exact mechanism of action is unknown.
b. May be bacteriostatic or bactericidal, depending on its concentration at the infection site and on the susceptibility of the infecting organism
c. Used with at least 1 other antitubercular medication if ineffectiveness of the primary medication(s) occurs
2. **Contraindications and cautions**
   a. Contraindicated in clients with hypersensitivity
   b. Used with caution in clients with diabetes mellitus, renal impairment, or gout and in children
   c. May decrease the effects of allopurinol, colchicine, and probenecid
   d. Cross-sensitivity is possible with isoniazid, ethionamide, or nicotinic acid.

3. **Side and adverse effects**
   a. Increases liver function tests and uric acid levels
   b. Arthralgia, myalgia
   c. Photosensitivity
   d. Hepatotoxicity
   e. Thrombocytopenia

4. **Interventions**
   a. Assess for hypersensitivity.
   b. Evaluate CBC, liver function test results, and uric acid levels.
   c. Observe for hepatotoxic effects; if they occur, withhold the medication and notify the PHCP.
   d. Assess for painful or swollen joints.
   e. Evaluate blood glucose level, because diabetes mellitus may be difficult to control while client is taking the medication.

5. **Client education**
   a. To take the medication with food to reduce gastrointestinal distress
   b. To avoid sunlight or ultraviolet light until photosensitivity is determined

---

*Some tuberculosis medications can cause red-orange–colored body secretions. Inform the client that this is not a harmful effect but that the secretions can stain and permanently discolor items.*
XV. Second-Line Medications for Tuberculosis (see Box 51-7)

A. Rifabutin

1. Description
   a. Inhibits mycobacterial DNA-dependent RNA polymerase and suppresses protein synthesis
   b. Used to prevent disseminated *Mycobacterium avium* complex (MAC) disease in clients with advanced HIV infection
   c. Used to treat active MAC disease and tuberculosis in clients with HIV infection

2. Cautions
   a. Can affect blood levels of some medications, including oral contraceptives and some medications used to treat HIV infection
   b. A nonhormonal method of birth control should be used instead of an oral contraceptive.

3. Side and adverse effects
   a. Rash
   b. Gastrointestinal disturbances
   c. Neutropenia
   d. Red-orange–colored body secretions
   e. Uveitis
   f. Myositis
   g. Arthralgia
   h. Hepatitis
   i. Chest pain with dyspnea
   j. Flu-like syndrome

4. Interventions
   a. Observe for hepatotoxic effects; if they occur, withhold the medication and notify the PHCP.
   b. Assess for painful or swollen joints.
   c. Assess for ocular pain or blurred vision.

5. Client education: That the medication can be taken without regard to food

B. Rifapentine
1. Description: Used only for pulmonary tuberculosis
2. Cautions: Can affect blood levels of some medications, including oral contraceptives and warfarin, and some medications used to treat HIV infection

3. Side and adverse effects
   a. Red-orange–colored body secretions
   b. Hepatotoxicity

4. Interventions
   a. Obtain baseline liver function studies and assess throughout therapy.
   b. Observe for hepatotoxic effects; if they occur, withhold the medication and notify the PHCP.

5. Client education
   a. That the medication can be taken without regard to food
   b. To avoid sunlight or ultraviolet light until photosensitivity is determined
   c. That red-orange–colored body secretions may occur

C. Capreomycin sulfate
1. Description
   a. Mechanism of action is unknown.
   b. Used to treat MDR-TB when significant resistance to other medications is expected
   c. Administered intramuscularly

2. Contraindications and cautions
   a. The risk of nephrotoxicity, ototoxicity, and neuromuscular blockade is increased with the use of aminoglycosides or loop diuretics.
   b. Used with caution in clients with renal insufficiency, acoustic nerve impairment, hepatic disorder, myasthenia gravis, or parkinsonism
   c. Not administered to clients receiving streptomycin

3. Side and adverse effects
   a. Nephrotoxicity
   b. Ototoxicity
   c. Neuromuscular blockade

4. Interventions
a. Perform baseline audiometric testing.
b. Assess renal, hepatic, and electrolyte levels before administration.
c. Monitor intake and output.
d. Reconstituted medication may be stored for 48 hours at room temperature.
e. Administer intramuscularly, deep into a large muscle mass.
f. Rotate injection sites.
g. Observe injection site for redness, excessive bleeding, and inflammation.

5. Client education
   a. Not to perform tasks that require mental alertness
   b. To report any hearing loss, balance disturbances, respiratory difficulty, weakness, or signs of hypersensitivity reactions

D. Antibiotics
   1. Description
      a. Aminoglycoside antibiotics or fluoroquinolones are given with at least 1 other antitubercular medication.
      b. Bactericidal because of receptor-binding action interfering with protein synthesis in susceptible microorganisms
      c. Gastrointestinal disturbances are the most common side effect.
      d. Fluoroquinolones are not recommended for use in children.

   2. Contraindications and cautions
      a. Contraindicated in clients with hypersensitivity, neuromuscular disorders, or eighth cranial nerve damage
      b. Used with caution in the older client, in neonates because of renal insufficiency and immaturity, and in young infants because it may cause CNS depression
      c. The risk of toxicity increases if taken with other aminoglycosides or
nephrotoxicity- or ototoxicity-producing medications.

3. Side and adverse effects
   a. Hypersensitivity
   b. Pain and irritation at the injection site
   c. Nephrotoxicity is indicated by increased blood urea nitrogen and serum creatinine levels.
   d. Ototoxicity is indicated by tinnitus, dizziness, ringing or roaring in the ears, and reduced hearing.
   e. Neurotoxicity is indicated by headache, dizziness, lethargy, tremors, and visual disturbances.
   f. Superinfections

4. Interventions
   a. Assess for hypersensitivity.
   b. Monitor for ototoxic, neurotoxic, and nephrotoxic reactions.
   c. Monitor liver and renal function test results.
   d. Obtain baseline audiometric test and repeat every 1 to 2 months, because the medication impairs the eighth cranial nerve.
   e. Assess acuteness of hearing.
   f. Monitor for visual changes.
   g. Assess hydration status and maintain adequate hydration during therapy.
   h. Monitor intake and output.
   i. Assess urinalysis.
   j. Monitor for superinfection.

5. Client education: To notify the PHCP if hearing loss, changes in vision, or urinary problems occur

E. Ethionamide
1. Description
   a. Mechanism of action is unknown.
   b. Used to treat MDR-TB when significant resistance to other medications is expected.
2. Contraindications and cautions
   a. Contraindicated in clients with hypersensitivity
   b. Used with caution in clients with diabetes mellitus or renal dysfunction

3. Side and adverse effects
   a. Anorexia, nausea, vomiting
   b. Metallic taste in the mouth
   c. Orthostatic hypotension
   d. Jaundice
   e. Mental changes
   f. Peripheral neuritis
   g. Rash

4. Interventions
   a. Assess liver and renal function test results.
   b. Monitor glucose levels in the client with diabetes mellitus.
   c. Administer pyridoxine as prescribed to reduce the risk of neurotoxicity.

5. Client education
   a. To take medication with food or meals to minimize gastrointestinal irritation
   b. To change positions slowly
   c. To report signs of a rash, which can progress to exfoliative dermatitis if the medication is not discontinued

F. Aminosalicylic acid
1. Description
   a. Inhibits folic acid metabolism in mycobacteria
   b. Used to treat MDR-TB when significant resistance to other medications is expected

2. Contraindications and cautions
   a. Contraindicated with hypersensitivity to aminosalicylates,
salicylates, or compounds containing the *para*-aminophenol group.
b. Aminobenzoates block the absorption of aminosalicylate sodium.

3. Side and adverse effects
   a. Hypersensitivity
   b. Bitter taste in the mouth
   c. Gastrointestinal tract irritation
   d. Exfoliative dermatitis
   e. Blood dyscrasias
   f. Crystalluria
   g. Changes in thyroid function

4. Interventions
   a. Assess for hypersensitivity.
   b. Offer water to rinse the mouth and chewing gum or hard candy to alleviate the bitter taste.
   c. Encourage fluid intake to prevent crystalluria.
   d. Monitor intake and output.

5. Client education
   a. To discard the medication and obtain a new supply if a purplish-brown discoloration occurs
   b. To take the medication with food
   c. That urine may turn red on contact with hypochlorite bleach if bleach was used to clean a toilet
   d. Not to take aspirin or over-the-counter medications without the PHCP’s approval
   e. To report signs of a blood dyscrasia, such as sore throat or mouth, malaise, fatigue, bruising, or bleeding

G. Cycloserine
   1. Description
      a. Interferes with cell wall biosynthesis
      b. Used to treat MDR-TB when significant resistance to other medications is expected

   2. Contraindications and cautions
      a. Use of alcohol or ethionamide increases the risk of seizures
      b. Used with caution in clients with a
seizure disorder, depression, severe anxiety, psychosis, or renal insufficiency or in clients who use alcohol.

3. Side and adverse effects
   a. Hypersensitivity
   b. CNS reactions
   c. Neurotoxicity
   d. Seizures
   e. Heart failure
   f. Headache
   g. Vertigo
   h. Altered level of consciousness
   i. Irritability, nervousness, anxiety
   j. Confusion
   k. Mood changes, depression, thoughts of suicide

4. Interventions
   a. Monitor level of consciousness.
   b. Monitor for changes in mental status and thought processes.
   c. Monitor renal and hepatic function tests.
   d. Monitor serum medication level to avoid the risk of neurotoxicity; the peak concentration, measured 2 hours after dosing, should be 25 to 35 mcg/mL (140 to 195 mcmol/L).

5. Client education
   a. To take the medication after meals to prevent gastrointestinal upset
   b. To report signs of a rash or signs of CNS toxicity
   c. To avoid driving or performing tasks that require alertness until the reaction to the medication has been determined
   d. About the need for monitoring serum medication levels weekly, as prescribed

H. Streptomycin
1. Description
   a. An aminoglycoside antibiotic used with at least 1 other antitubercular medication
   b. Bactericidal because of receptor-binding
action that interferes with protein synthesis in susceptible organisms

2. Contraindications and cautions
   a. Contraindicated in clients with hypersensitivity, myasthenia gravis, parkinsonism, or eighth cranial nerve damage
   b. Used with caution in the older client, in neonates because of renal insufficiency and organ immaturity, and in young infants because the medication may cause CNS depression
   c. The risk of toxicity increases when taken with other aminoglycosides or nephrotoxicity- or ototoxicity-producing medications.

3. Side and adverse effects (Box 51-8)

4. Interventions
   a. Assess for hypersensitivity.
   b. Monitor liver and renal function test results.
   c. Monitor for ototoxic, neurotoxic, and nephrotoxic reactions.
   d. Perform baseline audiometric testing and repeat every 1 to 2 months, because the medication impairs the eighth cranial nerve.
   e. Monitor for visual changes.
   f. Assess hydration status and maintain adequate hydration during therapy.
   g. Monitor intake and output.
   h. Assess urinalysis results.
   i. Monitor for signs of peripheral neuritis.

5. Client education: To notify the PHCP if hearing loss, changes in vision, or urinary problems occur

XVI. Influenza Medications
   A. Vaccines
      1. Description
      2. Because the strain of influenza virus is different every year, annual vaccination is recommended (usually sometime during September to April); each time a flu vaccine is administered, the nurse should inform the client of any updated information regarding the vaccine.
The trivalent influenza vaccine includes vaccination against H1N1 and H3N2 strains (influenza A strains) and an influenza B strain. Because the strain of influenza virus is different every year, vaccine components may change. The vaccine is recommended for all individuals unless a contraindication to receiving it exists.

a. The nasal spray (live) vaccine, if available, is approved only for healthy people ages 2 through 49.
b. The nasal spray vaccine is not approved for pregnant women.
c. The flu shots (inactivated vaccine), depending on the manufacturer, are approved for children as young as 6 months of age and are safe for pregnant women.
d. The nasal spray contains a live flu virus that has been weakened to the point that it cannot cause the flu; its advantage is that it may elicit a stronger immune response than the flu shot in children who have never had the flu or a flu vaccine before.
e. The disadvantage of the nasal spray is that it may not be quite as protective as the flu shot for older people who have had the flu or flu vaccines before.
f. All individuals should receive an influenza vaccine. High-priority individuals include pregnant women; household contacts and caregivers of children younger than 6 months of age; people ages 6 months to 24 years; health care workers and emergency medical personnel; and adults ages 25 to 64 with a chronic medical condition, such as asthma, or a weakened immune system, which increases the risk of flu complications.

3. Contraindications and cautions

a. Contraindications of the inactivated vaccine include hypersensitivity, active infection, Guillain-Barré syndrome, active febrile illness, and children younger than 6 months.
b. Contraindications of the live attenuated vaccine include age younger than 2
years or adults 50 years or older; pregnant women; children or adolescents on long-term aspirin therapy; and those with severe nasal congestion or long-term conditions such as asthma; diabetes mellitus; anemia or blood disorders; or heart, kidney, or lung disease.

4. Side and adverse effects
   a. Inactivated vaccine: Localized pain and swelling at the injection site, general body aches and pains, malaise, fever
   b. Attenuated vaccine: Runny nose or nasal congestion, cough, headache, sore throat

5. Interventions
   a. The intramuscular route is recommended for the inactivated vaccine; adults and older children should be vaccinated in the deltoid muscle.
   b. Monitor for side and adverse effects of the vaccine.
   c. Monitor for hypersensitivity reactions in clients receiving vaccination for the first time.

6. Client education
   a. About the importance of an annual vaccination
   b. That the inactivated vaccine contains noninfectious, killed viruses and cannot cause influenza
   c. That any respiratory disease unrelated to influenza can occur after the vaccination
   d. That if the attenuated vaccine is received, the virus may be shed in secretions up to 2 days after vaccination
   e. That development of antibodies in adults takes approximately 2 weeks

C. Antiviral medications (Table 51-1)
   1. Description
      a. Use during outbreaks of influenza depends on the current strain of
influenza
b. Diagnosis of influenza should include rapid diagnostic tests, because infection from other pathogens may cause symptoms similar to those of influenza infection.
c. May also be administered as prophylaxis against infection but should not replace vaccination

2. Contraindicated in hypersensitive clients
3. Side and adverse effects (see Table 51-1)
4. Interventions
   a. Administer within 2 days of onset of symptoms and continue for the entire prescription.
b. Monitor for side and adverse effects of specific medications.

5. Client education
   a. That the medication may not prevent the transmission of influenza to others
   b. About the need to adjust activities if dizziness or fatigue occur
   c. About management of side and adverse effects of various medications
   d. To take medication exactly as prescribed and for the duration of prescription

XVII. Pneumococcal Conjugate Vaccine
A. Pneumococcal conjugate vaccine is used for the prevention of invasive pneumococcal disease in infants and children.
B. Pneumococcal polysaccharide vaccine is used for adults and high-risk children older than 2 years.
C. Side and adverse effects may include erythema, swelling, pain, and tenderness at the injection site; fever; irritability; drowsiness; and reduced appetite.
D. See Chapter 40 for additional information about vaccines for pneumonia.
Inhaled medications commonly used in asthma treatment include β-adrenergic bronchodilators, cromolyn sodium, and aerosol glucocorticoids. A, The metered-dose inhaler may be held about 2 fingerwidths (1.5 inches [4 cm]) in front of the mouth. B, Alternatively, an inhaler with a spacer device can be used. Clients should breathe deeply once before activating the inhaler and then continue breathing in for about 5 seconds. Clients then should hold their breath for 10 to 15 seconds before breathing out slowly. If a second dose is needed, clients should wait 1 to 2 minutes before taking the second dose.

**Box 51-1**

**Medications to Treat Restrictive Airway Problems**

**Bronchodilators**

β₂-Adrenergic Agonists

Inhaled

- Albuterol
- Arformoterol
- Formoterol
- Levalbuterol
- Salmeterol

Oral

- Albuterol
- Terbutaline

Methylxanthines

- Theophylline, oral
- Aminophylline

Anticholinergics
Ipratropium, inhaled
Tiotropium, inhaled
Aclidinium, inhaled
Umeclidinium, inhaled

Glucocorticoids (Corticosteroids)

Inhaled

- Beclomethasone dipropionate
- Budesonide
- Ciclesonide
- Flunisolide
- Fluticasone propionate
- Mometasone furoate
- Triamcinolone acetonide

Oral

- Prednisone
- Prednisolone

Leukotriene Modifiers

- Montelukast, oral
- Zafirlukast, oral
- Zileuton, oral

Inhaled Nonsteroidal Antiallergy Agent

- Cromolyn sodium, inhaled

Monoclonal Antibody

- Omalizumab

**Second-Line Agents**
Box 51-8
Side and Adverse Effects of Streptomycin

Nephrotoxicity

• Changes in urine output
• Decreased appetite
• Increased thirst
• Nausea, vomiting

Neurotoxicity

• Muscle numbness
• Seizures
• Tingling
• Twitching

Vestibular Toxicity

• Clumsiness
• Dizziness
• Unsteadiness

Auditory Toxicity (Ototoxicity)

• A full feeling in the ears
• Ringing in the ears
• Loss of hearing

### Practice Questions

583. A client has a prescription to take guaifenesin. The nurse determines that the client understands the proper administration of this medication if the client states that she or he will perform which action?

1. Take an extra dose if fever develops
2. Take the medication with meals only
3. Take the tablet with a full glass of water
4. Decrease the amount of daily fluid intake

584. The nurse is preparing to administer a dose of naloxone intravenously to a client with an opioid overdose. Which supportive medical equipment should the nurse plan to have at the client’s bedside?

1. Nasogastric tube
2. Paracentesis tray
3. Resuscitation equipment
4. Central line insertion tray

585. The nurse teaches a client about the effects of diphenhydramine, which has been prescribed as a cough suppressant. The nurse determines that the client needs further instruction if the client makes which statement?

1. “I will take the medication on an empty stomach.”
2. “I won’t drink alcohol while taking this medication.”
3. “I won’t do activities that require mental alertness while taking this medication.”
4. “I will use sugarless gum, candy, or oral rinses to decrease dryness in my mouth.”

586. A cromolyn sodium inhaler is prescribed for a client with allergic asthma. The nurse provides instructions regarding the adverse effects of this medication and should tell the client that which undesirable effect is associated with this medication?

1. Insomnia
2. Constipation
3. Hypotension
4. Bronchospasm

587. Terbutaline is prescribed for a client with bronchitis. Which disorder in the client’s medical history requires caution by the nurse?
1. Osteoarthritis
2. Hypothyroidism
3. Diabetes mellitus
4. Polycystic disease

588. Zafirlukast is prescribed for a client with bronchial asthma. Which laboratory test does the nurse expect to be prescribed before the administration of this medication?
   1. Platelet count
   2. Neutrophil count
   3. Liver function tests
   4. Complete blood count

589. A client has been taking isoniazid for 2 months. The client complains to the nurse about numbness, paresthesias, and tingling in the extremities. The nurse interprets that the client is experiencing which problem?
   1. Hypercalcemia
   2. Peripheral neuritis
   3. Small blood vessel spasm
   4. Impaired peripheral circulation

590. A client is to begin a 6-month course of therapy with isoniazid. The nurse should plan to teach the client to take which action?
   1. Use alcohol in small amounts only.
   2. Report yellow eyes or skin immediately.
   3. Increase intake of Swiss or aged cheeses.
   4. Avoid vitamin supplements during therapy.

591. A client has been started on long-term therapy with rifampin. The nurse should provide which information to the client about the medication?
   1. Should always be taken with food or antacids
   2. Should be double-dosed if 1 dose is forgotten
   3. Causes orange discoloration of sweat, tears, urine, and feces
   4. May be discontinued independently if symptoms are gone in 3 months

592. The nurse has given a client taking ethambutol information about the medication. The nurse determines that the client understands the instructions if the client states that they will immediately report which finding?
   1. Impaired sense of hearing
   2. Gastrointestinal side effects
   3. Orange-red discoloration of body secretions
   4. Difficulty in discriminating the color red from green

593. A client with tuberculosis is starting antituberculosis therapy with isoniazid. Before giving the client the first dose, the nurse should ensure that which baseline study has been completed?
   1. Electrolyte levels
   2. Coagulation times
   3. Liver enzyme levels
   4. Serum creatinine level

594. The nurse has a prescription to give a client salmeterol, 2 puffs, and beclomethasone dipropionate, 2 puffs, by metered-dose inhaler. The nurse
should administer the medication using which procedure?
1. Beclomethasone first and then the salmeterol
2. Salmeterol first and then the beclomethasone
3. Alternating a single puff of each, beginning with the salmeterol
4. Alternating a single puff of each, beginning with the beclomethasone

595. Rifabutin is prescribed for a client with active *Mycobacterium avium* complex (MAC) disease and tuberculosis. The nurse should monitor for which side and adverse effects of rifabutin? **Select all that apply.**

- [ ] 1. Signs of hepatitis
- [ ] 2. Flu-like syndrome
- [ ] 3. Low neutrophil count
- [ ] 4. Vitamin B<sub>6</sub> deficiency
- [ ] 5. Ocular pain or blurred vision
- [ ] 6. Tingling and numbness of the fingers

596. A client begins therapy with theophylline. The nurse plans to teach the client to limit the intake of which items while taking this medication?
1. Coffee, cola, and chocolate
2. Oysters, lobster, and shrimp
3. Melons, oranges, and pineapple
4. Cottage cheese, cream cheese, and dairy creamers

597. The nurse has just administered the first dose of omalizumab to a client. Which statement by the client alerts the nurse of a life-threatening effect?
1. “I have a severe headache.”
2. “My feet are quite swollen.”
3. “I am nauseated and may vomit.”
4. “My lips and tongue are swollen.”

598. The nurse is teaching a client who is beginning antiviral therapy for influenza. Which statement by the client indicates an understanding of the instructions?
1. “I must take the medication exactly as prescribed.”
2. “Once I start the medication, I will no longer be contagious.”
3. “I will not get any colds or infections while taking this medication.”
4. “This medication has minimal side effects and I can return to normal activities.”

599. The nurse is caring for a client receiving an albuterol/ipratropium nebulized breathing treatment. Which report from the client should the nurse note as an expected side effect of this combination medication?
1. “I feel like my heart is racing.”
2. “I feel more bloated than usual.”
3. “My eyes have been watering lately.”
4. “I haven’t had a bowel movement in 4 days.”
583. **Answer:** 3

**Rationale:** Guaifenesin is an expectorant and should be taken with a full glass of water to decrease the viscosity of secretions. Extra doses should not be taken. The client should contact the primary health care provider if the cough lasts longer than 1 week or is accompanied by fever, rash, sore throat, or persistent headache. Fluids are needed to decrease the viscosity of secretions. The medication does not have to be taken with meals.

**Test-Taking Strategy:** Begin to answer this question by eliminating option 1 first, recalling that extra doses of medication should not be taken. Next, eliminate option 2 because of the closed-ended word “only.” Next, knowing that increased fluid helps liquefy secretions for more effective coughing directs you to the correct option.

**Level of Cognitive Ability:** Evaluating
**Client Needs:** Physiological Integrity
**Integrated Process:** Nursing Process—Evaluation
**Content Area:** Pharmacology: Respiratory Medications: Expectorants and Mucolytic Agents

---

584. **Answer:** 3

**Rationale:** The nurse administering naloxone for suspected opioid overdose should have resuscitation equipment readily available to support naloxone therapy if it is needed. Other adjuncts that may be needed include oxygen, a mechanical ventilator, and vasopressors.

**Test-Taking Strategy:** Focus on the subject, supportive medical equipment. Note the words opioid overdose. Recalling the effects of these types of medications will direct you to the correct option. The correct option is also the umbrella option.

**Level of Cognitive Ability:** Applying
**Client Needs:** Physiological Integrity
**Integrated Process:** Nursing Process—Planning
**Content Area:** Pharmacology: Respiratory Medications: Opioid Antagonists

---

585. **Answer:** 1

**Rationale:** Diphenhydramine has several uses, including as an antihistamine, antitussive, antidyskinetic, and sedative-hypnotic. Instructions for use include taking with food or milk to decrease gastrointestinal upset and using oral rinses, sugarless gum, or hard candy to minimize dry mouth. Because the medication causes
Drowsiness, the client should avoid use of alcohol or central nervous system depressants, operating a car, or engaging in other activities requiring mental awareness during use.

**Test-Taking Strategy:** Note the strategic words, needs further instruction. These words indicate a negative event query and ask you to select an option that is incorrect. Knowing that the medication has a sedative effect helps you eliminate options 2 and 3 first because they are comparable or alike. Recalling that the medication causes a dry mouth helps you choose the correct option as the answer, according to the way the question is stated.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Respiratory Medications: Antitussives

**Health Problem:** N/A

**Priority Concepts:** Client Education; Safety

**Reference:** Lilley et al. (2017), p. 575.

586. **Answer:** 4

**Rationale:** Cromolyn sodium is an inhaled nonsteroidal antiallergy agent and a mast cell stabilizer. Undesirable effects associated with inhalation therapy of cromolyn sodium are bronchospasm, cough, nasal congestion, throat irritation, and wheezing. Clients receiving this medication orally may experience pruritus, nausea, diarrhea, and myalgia.

**Test-Taking Strategy:** Note the words undesirable effect. This should assist in directing you to the correct option. In addition, use the ABCs—airway, breathing, and circulation—to select the correct option. The correct option addresses the airway.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Respiratory Medications: Restrictive Airway Disease Agents

**Health Problem:** Adult Health: Respiratory: Asthma

**Priority Concepts:** Client Education; Gas Exchange

587. **Answer:** 3

**Rationale:** Terbutaline is a bronchodilator and is contraindicated in clients with hypersensitivity to sympathomimetics. It should be used with caution in clients with impaired cardiac function, diabetes mellitus, hypertension, hyperthyroidism, or a history of seizures. The medication may increase blood glucose levels.

**Test-Taking Strategy:** Focus on the subject, cautions for using terbutaline. Specific knowledge regarding the contraindications and cautions associated with the use of this medication is needed to answer this question. Remember that terbutaline is used with caution in the client with diabetes mellitus.
Rationale: Zafirlukast is a leukotriene receptor antagonist used in the prophylaxis and long-term treatment of bronchial asthma. Zafirlukast is used with caution in clients with impaired hepatic function. Liver function laboratory tests should be performed to obtain a baseline, and the levels should be monitored during administration of the medication. It is not necessary to perform the other laboratory tests before administration of the medication.

Test-Taking Strategy: Eliminate options 2 and 4 first because they are comparable or alike, noting that a complete blood count would include a neutrophil count. From the remaining options, you would need to know that this medication affects hepatic function.

Rationale: Isoniazid is an antitubercular medication. A common side effect of isoniazid is peripheral neuritis, manifested by numbness, tingling, and paresthesias in the extremities. This can be minimized with pyridoxine (vitamin B₆) intake. Options 1, 3, and 4 are not associated with the information in the question.

Test-Taking Strategy: Focus on the information in the question, numbness, paresthesias, and tingling in the extremities. Options 3 and 4 would not cause the symptoms presented in the question but instead would cause pallor and coolness. From the remaining options, you should know that peripheral neuritis is an adverse effect of isoniazid, and that these signs and symptoms do not correlate with hypercalcemia.
**Priority Concepts:** Clinical Judgment; Perfusion

590. **Answer:** 2

**Rationale:** Isoniazid is hepatotoxic, and therefore the client is taught to report signs and symptoms of hepatitis immediately, which include yellow skin and sclera. For the same reason, alcohol should be avoided during therapy. The client should avoid intake of Swiss cheese, fish such as tuna, and foods containing tyramine, because they may cause a reaction characterized by redness and itching of the skin, flushing, sweating, tachycardia, headache, or lightheadedness. The client can avoid developing peripheral neuritis by increasing the intake of pyridoxine (vitamin $B_6$) during the course of isoniazid therapy.

**Test-Taking Strategy:** Focus on the subject, client teaching for isoniazid. Because alcohol intake is prohibited with the use of many medications, eliminate option 1 first. Because the client receiving this medication typically is given supplements of vitamin $B_6$, option 4 is incorrect and is eliminated next. Recalling that the medication is hepatotoxic will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Respiratory Medications: Tuberculosis Medications

**Health Problem:** Adult Health: Respiratory: Tuberculosis

**Priority Concepts:** Client Education; Safety

591. **Answer:** 3

**Rationale:** Rifampin causes orange-red discoloration of body secretions and will stain soft contact lenses permanently. Rifampin should be taken exactly as directed. Doses should not be doubled or skipped. The client should not stop therapy until directed to do so by a primary health care provider. It is best to administer the medication on an empty stomach unless it causes gastrointestinal upset, and then it may be taken with food. Antacids, if prescribed, should be taken at least 1 hour before the medication.

**Test-Taking Strategy:** Options 2 and 4 are comparable or alike and are inaccurate, based on general guidelines for medication administration; the client should not double-dose or discontinue medication independently. Eliminate option 1 next because of the closed-ended word “always.”

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Respiratory Medications: Tuberculosis Medications

**Health Problem:** Adult Health: Respiratory: Tuberculosis

**Priority Concepts:** Client Education; Safety

**Reference:** Lewis et al. (2017), p. 509.
Rationale: Ethambutol causes optic neuritis, which decreases visual acuity and the ability to discriminate between the colors red and green. This poses a potential safety hazard when a client is driving a motor vehicle. The client is taught to report this symptom immediately. The client also is taught to take the medication with food if gastrointestinal upset occurs. Impaired hearing results from antitubercular therapy with streptomycin. Orange-red discoloration of secretions occurs with rifampin.

Test-Taking Strategy: Note the strategic word, immediately. Option 2 is the least likely symptom to report; instead, it should be managed by taking the medication with food. To select among the other options, you must know that this medication causes optic neuritis, resulting in difficulty with red-green discrimination.

Health Problem: Adult Health: Respiratory: Tuberculosis
Priority Concepts: Client Education; Safety

593. Answer: 3

Rationale: Isoniazid therapy can cause an elevation of hepatic enzyme levels and hepatitis. Therefore, liver enzyme levels are monitored when therapy is initiated and during the first 3 months of therapy. They may be monitored longer in the client who is older than 50 years or abuses alcohol. The laboratory tests in options 1, 2, and 4 are not necessary.

Test-Taking Strategy: Focus on the subject, the laboratory value to monitor. Recalling that this medication can be toxic to the liver will direct you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Pharmacology: Respiratory Medications: Tuberculosis Medications
Health Problem: Adult Health: Respiratory: Tuberculosis
Priority Concepts: Cellular Regulation; Safety

594. Answer: 2

Rationale: Salmeterol is an adrenergic type of bronchodilator, and beclomethasone dipropionate is a glucocorticoid. Bronchodilators are always administered before glucocorticoids when both are to be given on the same time schedule. This allows for widening of the air passages by the bronchodilator, which then makes the glucocorticoid more effective.

Test-Taking Strategy: Focus on the subject, the procedure for administering inhaled medications. To answer this question correctly, you must know two
different things. First, you must know that a bronchodilator is always given before a
glucocorticoid. This would allow you to eliminate options 3 and 4, because you
would not alternate the medications. To select between the remaining option and the
correct option, you must know that salmeterol is a bronchodilator, whereas
beclomethasone is a glucocorticoid.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Pharmacology: Respiratory Medications: Restrictive Airway Disease Agents

**Health Problem:** N/A

**Priority Concepts:** Gas Exchange; Safety

595. **Answer:** 1, 2, 3, 5

**Rationale:** Rifabutin may be prescribed for a client with active MAC disease and tuberculosis. It inhibits mycobacterial DNA-dependent RNA polymerase and suppresses protein synthesis. Side and adverse effects include rash, gastrointestinal disturbances, neutropenia (low neutrophil count), red-orange–colored body secretions, uveitis (blurred vision and eye pain), myositis, arthralgia, hepatitis, chest pain with dyspnea, and flu-like syndrome. Vitamin $B_6$ deficiency and numbness and tingling in the extremities are associated with the use of isoniazid.

**Test-Taking Strategy:** Focus on the subject, side and adverse effects of rifabutin. Specific knowledge is needed to answer correctly. Remember that hepatitis, flu-like syndrome, neutropenia, and uveitis can occur.

**Priority Concepts:** Clinical Judgment; Safety

596. **Answer:** 1

**Rationale:** Theophylline is a methylxanthine bronchodilator. The nurse teaches the client to limit the intake of xanthine-containing foods while taking this medication. These foods include coffee, cola, and chocolate.

**Test-Taking Strategy:** Focus on the subject, food items that need to be limited. Recall that theophylline is a xanthine bronchodilator and that intake of excessive amounts of foods naturally high in xanthines needs to be limited. Also, recalling that these medications cause cardiac and central nervous system stimulation will direct you to the correct option.

**Priority Concepts:** Client Education; Safety  
**Reference:** Lilley et al. (2017), pp. 585, 590.

597. **Answer:** 4

**Rationale:** Omalizumab is an antiinflammatory and monoclonal antibody used for long-term control of asthma. Anaphylactic reactions can occur with the administration of omalizumab. The nurse administering the medication should monitor for adverse reactions of the medication. Swelling of the lips and tongue are an indication of an anaphylaxis. The client statements in options 1, 2, and 3 are not indicative of an adverse reaction.

**Test-Taking Strategy:** Focus on the subject, a life-threatening effect. Recall that anaphylactic reactions can occur with the administration of omalizumab. Knowing the signs of a reaction will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity

**Content Area:** Pharmacology: Respiratory Medications: Restrictive Airway Disease Agents  
**Health Problem:** Adult Health: Respiratory: Asthma  
**Priority Concepts:** Clinical Judgment; Safety  
**Reference:** Skidmore-Roth (2017), pp. 879-880.

598. **Answer:** 1

**Rationale:** Antiviral medications for influenza must be taken exactly as prescribed. These medications do not prevent the spread of influenza, and clients are usually contagious for up to 2 days after the initiation of antiviral medications. Secondary bacterial infections may occur despite antiviral treatment. Side effects occur with these medications and may necessitate a change in activities, especially when driving or operating machinery if dizziness occurs.

**Test-Taking Strategy:** Focus on the subject, client instructions for antiviral therapy, and note the words indicates an understanding. Using general medication guidelines will direct you to the correct option.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Pharmacology: Immune Medications: Antivirals  
**Health Problem:** Adult Health: Respiratory: Viral, Bacterial, Fungal Infections  
**Priority Concepts:** Client Education; Infection  
**Reference:** Lilley et al. (2017), pp. 658.

599. **Answer:** 1
**Rationale:** Albuterol/ipratropium is a combination agent—one is a $\beta_2$-adrenergic agonist and the other is an anticholinergic medication, and in combination they produce an overall bronchodilation effect. Common side and adverse effects include headache, dizziness, dry mouth, tremors, nervousness, and tachycardia. Therefore, option 1 is correct. Options 2, 3, and 4 are not specifically associated with this medication.

**Test-Taking Strategy:** Begin to answer this question by eliminating options 2 and 4 first, noting they are comparable or alike. Next, eliminate option 3 because this medication causes anticholinergic effects such as dry eyes and dry mouth.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

UNIT XII
Cardiovascular Problems of the Adult Client
Introduction

Pyramid to Success

Pyramid Points focus on assessment data related to cardiovascular risks, health screening and promotion, complications of the various cardiovascular problems, emergency measures, and client education. Focus on the assessment findings and treatment in coronary artery disease, myocardial infarction, heart failure and pulmonary edema, pericarditis, aneurysms, hypertension, and arterial and venous problems. You must be able to identify the most common dysrhythmias and determine the appropriate interventions for these dysrhythmias, including the use of a pacemaker. Focus also on the care of the client following diagnostic treatments and surgical procedures. Note appropriate and therapeutic client positions, particularly with arterial and venous problems of the extremities. Focus on treatments and medications prescribed for the various cardiovascular problems and client teaching related to prescribed treatment plans. Be familiar with the components related to cardiac rehabilitation.

Client Needs: Learning Objectives

Safe and Effective Care Environment

Consulting with the interprofessional health care team
Establishing priorities
Maintaining asepsis
Maintaining standard and other precautions
Recognizing the need for consultations and referrals
Upholding client rights
Verifying that informed consent related to treatments and procedures has been obtained

Health Promotion and Maintenance

Discussing alterations in lifestyle
Mobilizing appropriate community resources
Performing cardiovascular assessment techniques
Preventing cardiovascular disease
Promoting cardiac rehabilitation
Providing health screening and health promotion programs
Teaching related to diet therapy, exercise, and medications

**Psychosocial Integrity**

- Assisting the client to accept lifestyle changes
- Considering religious, spiritual, and cultural influences on health
- Discussing grief and loss and end-of-life issues
- Discussing situational role changes
- Discussing unexpected body image changes
- Identifying coping mechanisms
- Identifying fear, anxiety, and denial
- Identifying support systems

**Physiological Integrity**

- Administering intravenous medications
- Discussing activity limitations and promoting rest and sleep
- Monitoring for complications related to cardiovascular problems
- Monitoring for therapeutic effects of medications
- Monitoring hemodynamics
- Monitoring of cardiac enzyme and troponin levels and other cardiovascular-related laboratory values
- Providing interventions required in emergencies
- Providing nonpharmacological and pharmacological comfort interventions
- Responding to medical emergencies
CHAPTER 52

Cardiovascular Problems

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Health Promotion; Perfusion

I. Anatomy and Physiology
   A. Heart and heart wall layers
      1. The heart is located in the left side of the mediastinum.
      2. The heart consists of 3 layers.
         a. The epicardium is the outermost layer of the heart.
         b. The myocardium is the middle layer and is the actual contracting muscle of the heart.
         c. The endocardium is the innermost layer and lines the inner chambers and heart valves.
   B. Pericardial sac
      1. Encases and protects the heart from trauma and infection
      2. Has 2 layers
         a. The parietal pericardium is the tough, fibrous outer membrane that attaches anteriorly to the lower half of the sternum, posteriorly to the thoracic vertebrae, and inferiorly to the diaphragm.
         b. The visceral pericardium is the thin, inner layer that closely adheres to the heart.
      3. The pericardial space is between the parietal and visceral layers; it holds 5 to 20 mL of pericardial fluid, lubricates the pericardial surfaces, and cushions the heart.
   C. There are 4 heart chambers.
      1. The right atrium receives deoxygenated blood from the body via the superior and inferior vena cava.
      2. The right ventricle receives blood from the right atrium and pumps it to the lungs via the pulmonary
artery.
3. The left atrium receives oxygenated blood from the lungs via 4 pulmonary veins.
4. The left ventricle is the largest and most muscular chamber; it receives oxygenated blood from the lungs via the left atrium and pumps blood into the systemic circulation via the aorta.

D. There are 4 valves in the heart.
1. There are 2 atrioventricular valves, the tricuspid and the mitral, which lie between the atria and ventricles.
   a. The tricuspid valve is located on the right side of the heart.
   b. The bicuspid (mitral) valve is located on the left side of the heart.
   c. The atrioventricular valves close at the beginning of ventricular contraction and prevent blood from flowing back into the atria from the ventricles; these valves open when the ventricles relax.
2. There are 2 semilunar valves, the pulmonic and the aortic.
   a. The pulmonic semilunar valve lies between the right ventricle and the pulmonary artery.
   b. The aortic semilunar valve lies between the left ventricle and the aorta.
   c. The semilunar valves prevent blood from flowing back into the ventricles during relaxation; they open during ventricular contraction and close when the ventricles begin to relax.

E. Sinoatrial (SA) node
1. The main pacemaker that initiates each heartbeat
2. It is located at the junction of the superior vena cava and the right atrium.
3. The SA node generates electrical impulses at 60 to 100 times per minute and is controlled by the sympathetic and parasympathetic nervous systems.

F. Atrioventricular (AV) node
1. Located in the lower aspect of the atrial septum
2. Receives electrical impulses from the SA node
3. If the SA node fails, the AV node can initiate and sustain a heart rate of 40 to 60 beats per minute.

G. The bundle of His
1. A continuation of the AV node; located at the interventricular septum
2. It branches into the right bundle branch, which extends down the right side of the interventricular
septum; and the left bundle branch, which extends into the left ventricle.
3. The right and left bundle branches terminate in the Purkinje fibers.

H. Purkinje fibers
1. Purkinje fibers are a diffuse network of conducting strands located beneath the ventricular endocardium.
2. These fibers spread the wave of depolarization through the ventricles.
3. Purkinje fibers can act as the pacemaker with a rate between 20 and 40 beats per minute when higher pacemakers (such as the SA and AV nodes) fail.

I. Coronary arteries (Fig. 52-1)
1. The right main coronary artery supplies the right atrium and ventricle, the inferior portion of the left ventricle, the posterior septal wall, and the SA and AV nodes.
2. The left main coronary artery consists of 2 major branches, the left anterior descending (LAD) and the circumflex arteries.
3. The LAD artery supplies blood to the anterior wall of the left ventricle, the anterior ventricular septum, and the apex of the left ventricle.
4. The circumflex artery supplies blood to the left atrium and the lateral and posterior surfaces of the left ventricle.

The coronary arteries supply the capillaries of the myocardium with blood. If blockage occurs in these arteries, the client is at risk for myocardial infarction (MI).

J. Heart sounds
1. The first heart sound (S₁) is heard as the atrioventricular valves close and is heard loudest at the apex of the heart.
2. The second heart sound (S₂) is heard when the semilunar valves close and is heard loudest at the base of the heart.
3. A third heart sound (S₃) may be heard if ventricular wall compliance is decreased and structures in the ventricular wall vibrate; this can occur in conditions such as heart failure or valvular regurgitation. However, a third heart sound may be normal in individuals younger than 30 years.
4. A fourth heart sound (S₄) may be heard on atrial systole if resistance to ventricular filling is present;
this is an abnormal finding, and the causes include cardiac hypertrophy, disease, or injury to the ventricular wall.

K. Heart rate

1. The faster the heart rate, the less time the heart has for filling. At very fast rates the cardiac output decreases.
2. The normal sinus heart rate is 60 to 100 beats per minute.
3. Sinus tachycardia is a rate more than 100 beats per minute.
4. Sinus bradycardia is a rate less than 60 beats per minute.

L. Autonomic nervous system

1. Stimulation of sympathetic nerve fibers releases the neurotransmitter norepinephrine, producing an increased heart rate, increased conduction speed through the AV node, increased atrial and ventricular contractility, and peripheral vasoconstriction. Stimulation occurs when a decrease in pressure is detected.
2. Stimulation of the parasympathetic nerve fibers releases the neurotransmitter acetylcholine, which decreases the heart rate and lessens atrial and ventricular contractility and conductivity. Stimulation occurs when an increase in pressure is detected.

M. Blood pressure (BP) control

1. Baroreceptors (specialized nerve endings affected by changes in the arterial BP), also called pressoreceptors, are located in the walls of the aortic arch and carotid sinuses.
2. Increases in arterial pressure stimulate baroreceptors, and the heart rate and arterial pressure decrease.
3. Decreases in arterial pressure reduce stimulation of the baroreceptors and vasoconstriction occurs, as does an increase in heart rate.
4. Stretch receptors, located in the vena cava and the right atrium, respond to pressure changes that affect circulatory blood volume.
5. When the BP decreases as a result of hypovolemia, a sympathetic response occurs, causing an increased heart rate and blood vessel constriction; when the BP increases as a result of hypervolemia, an opposite effect occurs.
6. Antidiuretic hormone (vasopressin) influences BP indirectly by regulating vascular volume.
7. Increases in blood volume result in decreased antidiuretic hormone release, increasing diuresis,
8. Decreases in blood volume result in increased antidiuretic hormone release; this promotes an increase in blood volume and therefore BP.

9. Renin, a potent vasoconstrictor, causes the BP to increase.

10. Renin converts angiotensinogen to angiotensin I; angiotensin I is then converted to angiotensin II in the lungs.

11. Angiotensin II stimulates the release of aldosterone, which promotes water and sodium retention by the kidneys; this action increases blood volume and BP.

N. The vascular system

1. Arteries are vessels through which the blood passes away from the heart to various parts of the body; they convey highly oxygenated blood from the left side of heart to the tissues.

2. Arterioles control the blood flow into the capillaries.

3. Capillaries allow the exchange of fluid and nutrients between the blood and the interstitial spaces.

4. Venules receive blood from the capillary bed and move blood into the veins.

5. Veins transport deoxygenated blood from the tissues back to the right heart and then to the lungs for oxygenation.

6. Valves help return blood to the heart against the force of gravity.

7. The lymphatics drain the tissues and return the tissue fluid to the blood.

II. Diagnostic Tests and Procedures (refer to Chapter 10 for further information on laboratory reference levels)

A. Cardiac markers

1. Troponin

   a. Troponin is composed of 3 proteins—troponin C, cardiac troponin I, and cardiac troponin T.

   b. Troponin I especially has a high affinity for myocardial injury; it rises within 3 hours and persists for up to 7 to 10 days.

   c. Normal values are low, with troponin I being less than 0.35 ng/mL (less than 0.35 mcg/L) and troponin T being less than 0.1 ng/mL (less than 0.1 mcg/L); thus, any rise can indicate myocardial
cell damage.

2. CK-MB (creatine kinase, myocardial muscle)
   a. An elevation in value indicates myocardial damage.
   b. An elevation occurs within hours and peaks at 18 hours following an acute ischemic attack.
   c. Normal value for CK-MB (CK-2) is 2 to 6 ng/mL (2 to 6 mcg/L) for males and 2 to 5 ng/mL (2 to 5 mcg/L) for females.

3. Myoglobin
   a. Myoglobin is an oxygen-binding protein found in cardiac and skeletal muscle.
   b. The level rises within 2 hours after cell death, with a rapid decline in the level after 7 hours; however, it is not cardiac specific.

B. Complete blood count
   1. The red blood cell count decreases in rheumatic heart disease and infective endocarditis and increases in conditions characterized by inadequate tissue oxygenation.
   2. The white blood cell count increases in infectious and inflammatory diseases of the heart and after MI, because large numbers of white blood cells are needed to dispose of the necrotic tissue resulting from the infarction.
   3. An elevated hematocrit level can result from vascular volume depletion.
   4. Decreases in hemoglobin and hematocrit levels can indicate anemia.

C. Blood coagulation factors: An increase in coagulation factors can occur during and after MI, which places the client at greater risk for thrombophlebitis and formation of clots in the coronary arteries.

D. Serum lipids (refer to Chapter 10)
   1. The lipid profile measures serum cholesterol, triglyceride, and lipoprotein levels.
   2. The lipid profile is used to assess the risk of developing coronary artery disease.
   3. Lipoprotein-a or Lp(a), a modified form of low-density lipoprotein (LDL), increases atherosclerotic plaques and increases clots; value should be less than 30 mg/dL (300 mg/L).
E. Homocysteine: Elevated levels may increase the risk of cardiovascular disease; normal value is 4.5 to 11.9 mcmol/L (4.5 to 11.9 mcmol/L), age and gender dependent.

F. Highly sensitive C-reactive protein (hsCRP): Detects an inflammatory process such as that associated with the development of atherothrombosis; a level less than 1 mg/L is considered low risk, and a level greater than 3 mg/L places the client at high risk for heart disease.

G. Microalbuminuria: A small amount of protein in the urine has been a marker for endothelial dysfunction in cardiovascular disease.

H. Electrolytes (refer to Chapters 8 and 10)
   1. Potassium
      a. Hypokalemia causes increased cardiac electrical instability, ventricular dysrhythmias, and increased risk of digoxin toxicity.
      b. In hypokalemia, the electrocardiogram (ECG) shows flattening and inversion of the T wave, the appearance of a U wave, and ST depression.
      c. Hyperkalemia causes asystole and ventricular dysrhythmias.
      d. In hyperkalemia, the ECG may show tall, peaked T waves, widened QRS complexes, prolonged PR intervals, or flat P waves.

   2. Sodium
      a. The serum sodium level decreases with the use of diuretics.
      b. The serum sodium level decreases in heart failure, indicating water excess.

I. Calcium
   1. Hypocalcemia can cause ventricular dysrhythmias, prolonged ST and QT intervals, and cardiac arrest.
   2. Hypercalcemia can cause a shortened ST segment and widened T wave, atrioventricular block, tachycardia or bradycardia, digitalis hypersensitivity, and cardiac arrest.

J. Phosphorus level: Phosphorus levels should be interpreted with calcium levels, because the kidneys retain or excrete one electrolyte in an inverse relationship to the other.

K. Magnesium
   1. A low magnesium level can cause ventricular tachycardia and fibrillation.
   2. Electrocardiographic changes that may be observed with hypomagnesemia include tall T waves and
depressed ST segments.
3. A high magnesium level can cause muscle weakness, hypotension, and bradycardia.
4. Electrocardiographic changes that may be observed with hypermagnesemia include a prolonged PR interval and widened QRS complex.

Electrolyte and mineral imbalances can cause cardiac electrical instability that can result in life-threatening dysrhythmias.

L. Blood urea nitrogen: The blood urea nitrogen level is elevated in heart disorders such as heart failure and cardiogenic shock that reduce renal circulation.
M. Blood glucose: An acute cardiac episode can elevate the blood glucose level.
N. B-type natriuretic peptide (BNP)
   1. BNP is released in response to atrial and ventricular stretch; it serves as a marker for heart failure.
   2. BNP levels should be less than 100 ng/mL (less than 100 mcg/L); the higher the level, the more severe the heart failure.
O. Chest x-ray
   1. Description: Radiography of the chest is done to determine anatomical changes such as the size, silhouette, and position of the heart.
   2. Interventions
      a. Prepare the client, explaining the purpose and procedure.
      b. Remove jewelry.
      c. Ensure that the client is not pregnant.

P. Electrocardiography (Box 52-1)
   1. Description: This common noninvasive diagnostic test records the electrical activity of the heart and is useful for detecting cardiac dysrhythmias, location and extent of MI, and cardiac hypertrophy, and for evaluation of the effectiveness of cardiac medications.
   2. Interventions
      a. Determine the client’s ability to lie still; advise the client to lie still, breathe normally, and refrain from talking during the test.
      b. Reassure the client that an electrical shock will not occur.
      c. Document any cardiac medications the client is taking.
Q. Holter monitoring
   1. Description
      a. A noninvasive test; the client wears a
monitor and an electrocardiographic tracing is recorded continuously over a period of 24 hours or more while the client performs her or his activities of daily living.

b. The monitor identifies dysrhythmias if they occur and evaluates the effectiveness of antidysrhythmics or pacemaker therapy.

2. Interventions

a. Instruct the client to resume normal daily activities and to maintain a diary documenting activities and any symptoms that may develop for correlation with the electrocardiographic tracing.

b. Instruct the client using a wired monitor to avoid tub baths, showers, or swimming, because they will interfere with the electrocardiographic recorder device.

R. Echocardiography

1. Description

a. This noninvasive procedure is based on the principles of ultrasound and evaluates structural and functional changes in the heart.

b. Used to detect valvular abnormalities, congenital heart defects, wall motion, ejection fraction, and cardiac function.

c. Transesophageal echocardiography may be performed, in which the echocardiogram is done through the esophagus to view the posterior structures of the heart; this is an invasive exam and requires preparation and care similar to endoscopy procedures.

2. Interventions: Advise the client to lie still, breathe normally, and refrain from talking during the test.

S. Exercise electrocardiography testing (stress test)

1. Description

a. This noninvasive test studies the heart during activity and detects and evaluates coronary artery disease.

b. Treadmill testing is the most commonly used mode of stress testing.
c. If the client is unable to tolerate exercise, an intravenous (IV) infusion of dipyridamole or dobutamine hydrochloride is given to dilate the coronary arteries and simulate the effect of exercise; the client may need to be NPO (nothing by mouth) for 3 to 6 hours preprocedure.

2. Preprocedure interventions
   a. Ensure that an informed consent is obtained if required.
   b. Encourage adequate rest the night before the procedure.
   c. Instruct the client having a noninvasive test to eat a light meal 1 to 2 hours before the procedure.
   d. Instruct the client to avoid smoking, alcohol, and caffeine before the procedure.
   e. Instruct the client to ask the primary health care provider (PHCP) or cardiologist about taking prescribed medication on the day of the procedure; theophylline products are usually withheld 12 hours before the test, and calcium channel blockers and beta blockers are usually withheld on the day of the test to allow the heart rate to increase during the stress portion of the test.
   f. Instruct the client to wear nonconstrictive, comfortable clothing and supportive rubber-soled shoes for the exercise stress test.
   g. Instruct the client to notify the PHCP if any chest pain, dizziness, or shortness of breath occurs during the procedure.

3. Postprocedure interventions: Instruct the client to avoid taking a hot bath or shower for at least 1 to 2 hours.

T. Myocardial nuclear perfusion imaging (MNPI)
   1. Description
   a. Nuclear cardiology involves the use of radionuclide techniques and scanning for cardiovascular assessment.
   b. The most common tests include technetium pyrophosphate scanning,
thallium imaging, and multigated cardiac blood pool imaging; these tests can evaluate cardiac motion and calculate the ejection fraction.

2. Preprocedure interventions
   a. Ensure that an informed consent is obtained.
   b. Inform the client that a small amount of radioisotope will be injected and that the radiation exposure and risks are minimal.

3. Postprocedure interventions
   a. Assess vital signs.
   b. Assess injection site for bleeding or discomfort.
   c. Inform the client that fatigue is possible.

U. Magnetic resonance imaging (MRI)

1. Description
   a. This is a noninvasive diagnostic test that produces an image of the heart or great vessels through the interaction of magnetic fields, radiowaves, and atomic nuclei.
   b. It provides information on chamber size and thickness, valve and ventricular function, and blood flow through the great vessels and coronary arteries.

2. Preprocedure interventions
   a. Evaluate the client for the presence of a pacemaker or other implanted items that present a contraindication to the test.
   b. Ensure that the client has removed all metallic objects such as a watch, jewelry, clothing with metal fasteners, and metal hair fasteners.
   c. Inform the client that she or he may experience claustrophobia while in the scanner.

V. Electrophysiological studies: An invasive procedure in which a programmed electrical stimulation of the heart is induced to cause dysrhythmias and conduction defects; assists in finding an accurate diagnosis and aids in determining treatment.

W. Electron-beam computed tomography (EBCT) scan: Determines whether calcifications are present in the arteries; a coronary artery calcium (CAC) score is provided (a score higher than 300 indicates high risk of myocardial infarction and requires intensive
preventive treatment).

X. Cardiac catheterization (Fig. 52-2)

1. Description

   a. An invasive test involving insertion of a catheter into the heart and surrounding vessels
   b. Obtains information about the structure and performance of the heart chambers and valves and the coronary circulation

2. Preprocedure interventions

   a. Ensure that informed consent has been obtained.
   b. Assess for allergies to seafood, iodine, or radiopaque dyes; if allergic, the client may be premedicated with antihistamines and corticosteroids to prevent a reaction.
   c. Withhold solid food for 6 to 8 hours and liquids for 4 hours as prescribed to prevent vomiting and aspiration during the procedure.
   d. Document the client’s height and weight, because these data will be needed to determine the amount of dye to be administered.
   e. Document baseline vital signs and note the quality and presence of peripheral pulses for postprocedure comparison.
   f. Inform the client that a local anesthetic will be administered before catheter insertion.
   g. Inform the client that she or he may feel a fluttery feeling as the catheter passes through the heart, a flushed and warm feeling when the dye is injected, a desire to cough, and palpitations caused by heart irritability.
   h. The insertion site is prepared by shaving or clipping the hair and cleaning with an antiseptic solution.
   i. Administer preprocedure medications such as sedatives if prescribed.
   j. Insert an IV line if prescribed.
If a client taking metformin is scheduled to undergo a procedure requiring the administration of iodine dye, the metformin is withheld for 24 hours prior to the procedure because of the risk of lactic acidosis. The medication is not resumed until prescribed by the PHCP (usually 48 hours after the procedure or after renal function studies are done and the results are evaluated).

3. Postprocedure interventions

a. Monitor vital signs and cardiac rhythm for dysrhythmias at least every 30 minutes for 2 hours initially.
b. Assess for chest pain and, if dysrhythmias or chest pain occurs, notify the PHCP.
c. Monitor peripheral pulses and the color, warmth, and sensation of the extremity distal to the insertion site at least every 30 minutes for 2 hours initially.
d. Notify the PHCP if the client reports numbness and tingling; if the extremity becomes cool, pale, or cyanotic; or if loss of the peripheral pulses occurs. This could indicate clot formation and is an emergency.
e. Apply a sandbag or compression device (if prescribed) to the insertion site to provide additional pressure if required.
f. Monitor for bleeding; if bleeding occurs, apply manual pressure immediately and notify the PHCP.
g. Monitor for hematoma; if a hematoma develops, notify the PHCP.
h. Keep the extremity extended for 4 to 6 hours, as prescribed, keeping the leg straight to prevent arterial occlusion.
i. Maintain strict bed rest for 6 to 12 hours, as prescribed; however, the client may turn from side to side. Do not elevate the head of the bed more than 15 degrees.
j. If the antecubital vessel was used, immobilize the arm with an armboard.
k. If the PHCP uses a vascular closure device to seal the arterial puncture site, there is no need for prolonged
compression or bed rest, and clients may be out of bed in 1 to 2 hours.
l. Encourage fluid intake, if not contraindicated, to promote renal excretion of the dye and to replace fluid loss caused by the osmotic diuretic effect of the dye.
m. Monitor for nausea, vomiting, rash, or other signs of hypersensitivity to the dye.

Y. Intravascular ultrasonography (IVUS): A catheter with a transducer is used as an alternative to injecting a dye into the coronary arteries and detects plaque distribution and composition; it also detects arterial dissection and the degree of stenosis of an occluded artery.

III. Therapeutic Management
A. Percutaneous transluminal coronary angioplasty (PTCA)
   1. Description (Fig. 52-3)
      a. An invasive, nonsurgical technique in which 1 or more coronary arteries are dilated with a balloon catheter to open the vessel lumen and improve arterial blood flow
      b. PTCA may be used for clients with an evolving MI, alone or in combination with medications, to achieve reperfusion.
      c. The client can experience reocclusion after the procedure; thus, the procedure may need to be repeated.
      d. Complications can include arterial dissection or rupture, embolization of plaque fragments, spasm, and acute MI.
      e. Firm commitment is needed on the client’s part to stop smoking, adhere to diet restrictions, lose weight, alter the exercise pattern, and stop any behaviors that lead to progressive artery occlusion.

   2. Preprocedure interventions
      a. Similar to preprocedure interventions for cardiac catheterization
      b. The PHCP may prescribe preprocedure medications, including acetylsalicylic
3. Postprocedure interventions

a. Similar to postprocedure intervention following cardiac catheterization
b. Administer anticoagulants and antiplatelets as prescribed to prevent thrombus formation.
c. IV nitroglycerin may be prescribed to prevent coronary artery vasospasm.
d. Encourage fluids, if not contraindicated, to enhance renal excretion of dye.
e. Instruct the client in the administration of prescribed medications; daily acetylsalicylic acid (aspirin) may be prescribed.
f. Assist the client with planning lifestyle modifications.

B. Laser-assisted angioplasty

1. Description

a. A laser probe is advanced through a cannula similar to that used for PTCA.
b. Used for clients with small occlusions in the coronary arteries, also the distal superficial femoral, proximal popliteal, and common iliac arteries.
c. Heat from the laser vaporizes the plaque to open the occluded artery.

2. Preprocedure and postprocedure interventions

a. Care is similar to that for PTCA.
b. Monitor for complications of coronary dissection, acute occlusion, perforation, embolism, and MI.

C. Coronary artery stents

1. Description

a. Coronary artery stents are used with PTCA to provide a supportive scaffold to eliminate the risk of acute coronary vessel closure and to improve long-term patency of the vessel.
b. A balloon catheter bearing the stent is inserted into the coronary artery and
positioned at the site of occlusion; balloon inflation deploys the stent.  
c. When placed in the coronary artery, the stent reopens the blocked artery.

2. Preprocedure and postprocedure interventions  
a. Care is similar to that for PTCA.  
b. Acute thrombosis is a major concern following the procedure; the client is placed on antiplatelet therapy such as clopidogrel and acetylsalicylic acid (aspirin) for several months following the procedure. Length of time of antiplatelet therapy is determined by the type of stent (metal or medication-coated) that has been deployed.  
c. Monitor for complications of the procedure such as stent migration or occlusion, coronary artery dissection, and bleeding resulting from anticoagulation.

D. Atherectomy  
1. Description  
a. Atherectomy removes plaque from a coronary artery by the use of a cutting chamber on the inserted catheter or a rotating blade that pulverizes the plaque.  
b. Atherectomy is also used to improve blood flow to ischemic limbs in individuals with peripheral arterial disease.

2. Preprocedure and postprocedure interventions  
a. Care is similar to that for PTCA.  
b. Monitor for complications of perforation, embolus, and reocclusion.

E. Transmyocardial revascularization  
1. May be used for clients with widespread atherosclerosis involving vessels that are too small and numerous for replacement or balloon catheterization; performed through a small chest incision  
2. Transmyocardial revascularization uses a high-powered laser that creates 20 to 24 channels through the ventricular muscle of the left ventricle; blood enters these small channels, providing the affected region of the heart with oxygenated blood.
3. The opening on the surface of the heart heals; however, the main channels remain and perfuse the myocardium.

F. Coronary artery bypass grafting (Fig. 52-4)

1. Description

a. The occluded coronary arteries are bypassed with the client’s own venous or arterial blood vessels.

b. The saphenous vein, internal mammary artery, or other arteries may be used to bypass lesions in the coronary arteries.

c. Coronary artery bypass grafting is performed when the client does not respond to medical management of coronary artery disease or when vessels are severely occluded.

d. A minimally invasive direct coronary artery bypass (MIDCAB) may be an option for some clients who have a lesion in the LAD artery; a sternal incision is not required (usually a 2-inch [5-cm] left thoracotomy incision is done), and cardiopulmonary bypass is not required in this procedure.

2. Preoperative interventions

a. Familiarize the client and family with the cardiac surgical critical care unit.

b. Inform the client to expect a sternal incision, possible arm or leg incision(s), 1 or 2 chest tubes, a Foley catheter, and several IV fluid catheters.

c. Inform the client that an endotracheal tube will be in place for a short period of time and that she or he will be unable to speak.

d. Advise the client that she or he will be on mechanical ventilation and to breathe with the ventilator and not fight it.

e. Instruct the client that postoperative pain is expected and that pain medication will be available.

f. Instruct the client in how to splint the chest incision, cough and deep breathe, use the incentive spirometer, and perform arm and leg exercises.

g. Encourage the client and family to
3. Cardiac surgical unit postoperative interventions
   a. Mechanical ventilation is maintained for 6 to 24 hours as prescribed.
   b. The heart rate and rhythm, pulmonary artery and arterial pressures, urinary output, and neurological status are monitored closely.
   c. Mediastinal and pleural chest tubes to the water seal drainage system with prescribed suction are present; drainage exceeding 100 to 150 mL/hr is reported to the PHCP.
   d. Epicardial pacing wires are covered with sterile caps or connected to a temporary pacemaker generator; all equipment in use must be properly grounded to prevent microshock.
   e. Fluid and electrolyte balance is monitored closely; fluids are usually restricted to 1500 to 2000 mL, because the client usually has edema.
   f. The **blood pressure** is monitored closely, because hypotension can cause collapse of a vein graft; hypertension can cause increased pressure, promoting leakage from the suture line, causing bleeding.
   g. Temperature is monitored and rewarming procedures are initiated using warm or thermal blankets if the temperature drops below 96.8°F (36.0°C); rewarm the client no faster than 1.8 degrees/hr to prevent shivering, and discontinue rewarming procedures when the temperature approaches 98.6°F (37.0°C).
h. Potassium is administered intravenously as prescribed to maintain the potassium level between 4 and 5 mEq/L (4 to 5 mmol/L) to prevent dysrhythmias.

i. The client is monitored for signs of cardiac tamponade, which will include sudden cessation of previously heavy mediastinal drainage, jugular vein distention with clear lung sounds, equalization of right atrial (RA) pressure and pulmonary artery wedge pressure, and pulsus paradoxus.

j. Pain is monitored, differentiating sternotomy pain from anginal pain, which would indicate graft failure.

4. Alarm safety and alarm fatigue: Refer to Chapter 69.

5. Transfer of the client from the cardiac surgical unit

   a. Monitor vital signs, level of consciousness, and peripheral perfusion.
   b. Monitor for dysrhythmias.
   c. Auscultate lungs and assess respiratory status.
   d. Encourage the client to splint the incision, cough, deep breathe, and use the incentive spirometer to raise secretions and prevent atelectasis.
   e. Monitor temperature and white blood cell count, which, if elevated after 3 to 4 days, indicate infection.
   f. Provide adequate fluids and hydration as prescribed to liquefy secretions.
   g. Assess suture line and chest tube insertion sites for redness, purulent discharge, and signs of infection.
   h. Assess sternal suture line for instability, which may indicate infection.
   i. Guide the client to gradually resume activity.
   j. Assess the client for tachycardia, postural (orthostatic) hypotension, and fatigue before, during, and after activity.
   k. Discontinue activities if the BP drops more than 10 to 20 mm Hg or if the
pulse increases more than 10 beats per minute.

1. Monitor episodes of pain closely.
m. See **Box 52-2** for home care instructions.

G. Heart transplantation
1. A donor heart from an individual with a comparable body weight and ABO compatibility is transplanted into a recipient within less than 6 hours of procurement.
2. The surgeon removes the diseased heart, leaving the posterior portion of the atria to serve as an anchor for the new heart.
3. Because a remnant of the client’s atria remains, 2 unrelated P waves are noted on the ECG.
4. The transplanted heart is denervated and unresponsive to vagal stimulation; because the heart is denervated, clients do not experience angina.
5. Symptoms of heart rejection include hypotension, dysrhythmias, weakness, fatigue, and dizziness.
6. Endomyocardial biopsies are performed at regularly scheduled intervals and whenever rejection is suspected.
7. The client requires lifetime immunosuppressive therapy.
8. Strict aseptic technique and vigilant hand washing must be maintained when caring for the posttransplantation client because of increased risk for infection from immunosuppression.
9. The heart rate approximates 100 beats per minute and responds slowly to exercise or stress with regard to increases in heart rate, **contractility**, and **cardiac output**.

IV. Cardiac Dysrhythmias

A. Normal sinus rhythm (**Fig. 52-5**)
1. Rhythm originates from the SA node.
2. Description
   a. Atrial and ventricular rhythms are regular.
   b. Atrial and ventricular rates are 60 to 100 beats per minute (**Fig. 52-6** and **Box 52-3**).
   c. PR interval and QRS width are within normal limits.

B. Sinus bradycardia
1. Description
   a. Atrial and ventricular rhythms are
regular.

b. Atrial and ventricular rates are less than 60 beats per minute.
c. PR interval and QRS width are within normal limits.
d. Treatment may be necessary if the client is symptomatic (signs of decreased cardiac output).
e. A low heart rate may be normal for some individuals, such as athletes.

2. Interventions

a. Attempt to determine the cause of sinus bradycardia; withhold medication suspected of causing the bradycardia and notify the PHCP.
b. Administer oxygen as prescribed for the symptomatic client.
c. Administer atropine sulfate as prescribed to increase the heart rate to 60 beats per minute.
d. Be prepared to apply a noninvasive (transcutaneous) pacemaker initially if the atropine sulfate does not increase the heart rate sufficiently.
e. Avoid additional doses of atropine sulfate, because this will induce tachycardia.
f. Monitor for hypotension and administer fluids intravenously as prescribed.
g. Depending on the cause of the bradycardia, the client may need a permanent pacemaker.

C. Sinus tachycardia

1. Description

a. Atrial and ventricular rates are 100 to 180 beats per minute.
b. Atrial and ventricular rhythms are regular.
c. PR interval and QRS width are within normal limits.

2. Interventions

a. Identify the cause of the tachycardia.
b. Decrease the heart rate to normal by treating the underlying cause.
D. Atrial Fibrillation (Fig. 52-7)

1. Description
   a. Multiple rapid impulses from many foci depolarize in the atria in a totally disorganized manner at a rate of 350 to 600 times per minute.
   b. The atria quiver, which can lead to the formation of thrombi.
   c. Usually no definitive P wave can be observed, only fibrillatory waves before each QRS.

2. Interventions
   a. Administer oxygen.
   b. Administer anticoagulants as prescribed because of the risk of emboli.
   c. Administer cardiac medications as prescribed to control the ventricular rhythm and assist in the maintenance of cardiac output.
   d. Prepare the client for cardioversion as prescribed.
   e. Instruct the client in the use of medications as prescribed to control the dysrhythmia.

E. Premature Ventricular Contractions (PVCs; Fig. 52-8 and Box 52-4)

1. Description
   a. Early ventricular contractions result from increased irritability of the ventricles.
   b. PVCs frequently occur in repetitive patterns such as bigeminy, trigeminy, and quadrigeminy.
   c. The QRS complexes may be unifocal or multifocal.

2. Interventions
   a. Identify the cause and treat on the basis of the cause.
   b. Evaluate oxygen saturation to assess for hypoxemia, which can cause PVCs.
   c. Evaluate electrolytes, particularly the potassium level, because hypokalemia can cause PVCs.
   d. Oxygen and medication may be
prescribed in the case of acute myocardial ischemia or MI.

For the client experiencing PVCs, notify the PHCP or cardiologist if the client complains of chest pain or if the PVCs increase in frequency, are multifocal, occur on the T wave (R-on-T), or occur in runs of ventricular tachycardia.

F. Ventricular tachycardia (VT; Fig. 52-9)

1. Description
   a. VT occurs because of a repetitive firing of an irritable ventricular ectopic focus at a rate of 140 to 250 beats per minute or more.
   b. VT may present as a paroxysm of 3 self-limiting beats or more, or may be a sustained rhythm.
   c. VT can lead to cardiac arrest.

2. Stable client with sustained VT (with pulse and no signs or symptoms of decreased cardiac output)
   a. Administer oxygen as prescribed.
   b. Administer antidysrhythmics as prescribed.

3. Unstable client with VT (with pulse and signs and symptoms of decreased cardiac output)
   a. Administer oxygen and antidysrhythmic therapy as prescribed.
   b. Prepare for synchronized cardioversion if the client is unstable.
   c. The PHCP may attempt cough cardiopulmonary resuscitation (CPR) by asking the client to cough hard every 1 to 3 seconds.

4. Pulseless client with VT: Defibrillation and CPR

G. Ventricular fibrillation (VF; Fig. 52-10)

1. Description
   a. Impulses from many irritable foci in the ventricles fire in a totally disorganized manner.
   b. VF is a chaotic rapid rhythm in which the ventricles quiver and there is no
cardiac output.
c. VF is fatal if not successfully resolved within 3 to 5 minutes.
d. Client is unconscious with no pulse, BP, respirations, or heart sounds.

2. Interventions
   a. Initiate CPR until a defibrillator is available.
   b. The client is defibrillated immediately with 120 to 200 joules (biphasic defibrillator) or 360 joules (monophasic defibrillator); check the entire length of the client 3 times to make sure no one is touching the client or the bed; when clear, proceed with defibrillation.
   c. CPR is continued for 2 minutes, and the cardiac rhythm is reassessed to determine the need for further countershock.
   d. Administer oxygen as prescribed.
   e. Administer antidysrhythmic therapy as prescribed.

H. Guidelines for performing adult CPR
   1. Follow CAB (compressions, airway, breathing) guidelines. If a victim is noted not breathing or only gasping, activate the emergency response system and obtain an automated external defibrillator (AED) or monophasic or biphasic defibrillator depending on the setting and equipment available.
   2. Check the carotid pulse for a maximum of 10 seconds.
   3. If no pulse is felt, begin chest compressions (100 to 120 per minute) at a depth of 2 inches (5 cm) for 2 minutes or 5 cycles of 30 compressions to 2 ventilations using a barrier device or bag valve mask.
   4. To provide ventilations, the head-tilt chin-lift maneuver, or jaw thrust technique is used if neck injury is suspected.
   5. Check rhythm and for presence of a pulse every 2 minutes or after 5 cycles (depending on the setting and equipment available, deliver a shock if indicated).
   6. Switch compression and ventilation roles if another rescuer is available, to avoid fatigue.
   7. Continue this process until the victim gains consciousness, starts breathing, or has a pulse.
   8. If the victim has a pulse but is not breathing, continue with rescue breathing until help arrives and advanced cardiovascular life support measures are instituted.
V. Management of Dysrhythmias

A. Vagal maneuvers

1. Description: Vagal maneuvers induce vagal stimulation of the cardiac conduction system and are used to terminate supraventricular tachydysrhythmias.

2. Carotid sinus massage
   a. The PHCP instructs the client to turn the head away from the side to be massaged.
   b. The PHCP massages over 1 carotid artery for a few seconds to determine whether a change in cardiac rhythm occurs.
   c. The client must be on a cardiac monitor; an electrocardiographic rhythm strip before, during, and after the procedure should be documented on the chart.
   d. Have a defibrillator and resuscitative equipment available.
   e. Monitor vital signs, cardiac rhythm, and level of consciousness following the procedure.

3. Valsalva maneuver
   a. The PHCP instructs the client to bear down or induces a gag reflex in the client to stimulate a vagal response.
   b. Monitor the heart rate, rhythm, and BP.
   c. Observe the cardiac monitor for a change in rhythm.
   d. Record an electrocardiographic rhythm strip before, during, and after the procedure.
   e. Provide an emesis basin if the gag reflex is stimulated, and initiate precautions to prevent aspiration.
   f. Have a defibrillator and resuscitative equipment available.

B. Cardioversion

1. Description
   a. Cardioversion is synchronized countershock to convert an

undesirable rhythm to a stable rhythm.
b. Cardioversion can be an elective procedure performed by the PHCP for stable tachydysrhythmias resistant to medical therapies or an emergent procedure for hemodynamically unstable ventricular or supraventricular tachydysrhythmias.
c. A lower amount of energy is used than with defibrillation.

d. The defibrillator is synchronized to the client’s R wave to avoid discharging the shock during the vulnerable period (T wave).
e. If the defibrillator is not synchronized, it could discharge on the T wave and cause VF.

2. Preprocedure interventions
a. If an elective procedure, ensure that informed consent is obtained.
b. Administer sedation as prescribed.
c. If an elective procedure, hold digoxin for 48 hours preprocedure as prescribed to prevent postcardioversion ventricular irritability.
d. If an elective procedure for atrial fibrillation or atrial flutter, the client should receive anticoagulant therapy for 4 to 6 weeks preprocedure, and a transesophageal echocardiogram (TEE) should be performed to rule out clots in the atria prior to the procedure.

3. During the procedure
a. Ensure that the skin is clean and dry in the area where the electrode pads/hands-off pads will be placed.
b. Stop the oxygen during the procedure to avoid a fire hazard.
c. Be sure that no one is touching the bed or the client when delivering the countershock (check the entire length of the client 3 times).
4. Postprocedure interventions
   a. Priority assessment includes ability of the client to maintain the airway and breathing.
   b. Resume oxygen administration as prescribed.
   c. Assess vital signs.
   d. Assess level of consciousness.
   e. Monitor cardiac rhythm.
   f. Monitor for indications of successful response, such as conversion to sinus rhythm, strong peripheral pulses, an adequate BP, and adequate urine output.
   g. Assess the skin on the chest for evidence of burns from the edges of the pads.

C. Defibrillation
   1. Defibrillation is an asynchronous countershock used to terminate pulseless VT or VF.
   2. The defibrillator is charged to 120 to 200 joules (biphasic) or 360 joules (monophasic) for 1 countershock from the defibrillator, and then CPR is resumed immediately and continued for 5 cycles or about 2 minutes.
   3. Reassess the rhythm after 2 minutes, and if VF or pulseless VT continues, the defibrillator is charged to give a second shock at the same energy level previously used.
   4. Resume CPR after the shock, and continue with the life support protocol.

D. Use of pad electrodes
   1. One pad is placed at the third intercostal space to the right of the sternum; the other is placed at the fifth intercostal space on the left midaxillary line.
   2. Apply firm pressure of at least 25 lb to each of the pads.
   3. Be sure that no one is touching the bed or the client when delivering the countershock.
   4. Pads for hands-off biphasic defibrillation may be applied in an anterior-posterior position or apex-
posterior position, and placement directly over breast tissue should be avoided.

E. Automated external defibrillator (AED)

1. An AED is used by laypersons and emergency medical technicians for prehospital cardiac arrest.
2. Place the client on a firm, dry surface.
3. Turn on the AED and follow the voice prompts.
4. Place the electrode patches in the correct position on the client’s chest.
5. Stop CPR.
6. Ensure that no one is touching the client to avoid motion artifact during rhythm analysis.
7. The machine will advise whether a shock is necessary.
8. Shocks are recommended for pulseless VT or VF only (usually 3 shocks are delivered).
9. If unsuccessful, CPR is continued for 1 minute and then another series of shocks is delivered.

F. Automated implantable cardioverter-defibrillator (AICD)

1. Description
   a. An AICD monitors cardiac rhythm and detects and terminates episodes of VT and VF by delivering 25 to 30 joules up to 4 times, if necessary.
   b. An AICD is used in clients with episodes of spontaneous sustained VT or VF unrelated to an MI or in clients whose medication therapy has been unsuccessful in controlling life-threatening dysrhythmias.
   c. Transvenous electrode leads are placed in the right atrium and ventricle in contact with the endocardium; leads are used for sensing, pacing, and delivery of cardioversion or defibrillation.
   d. The generator is most commonly implanted in the left pectoral region.
   e. Instruct the client in the basic functions of the AICD.
   f. Know the rate cutoff of the AICD and the number of consecutive shocks that it will deliver.
   g. Wear loose-fitting clothing over the AICD generator site.
h. Instruct the client on activities to avoid, including contact sports, to prevent trauma to the AICD generator and lead wires.
i. Report any fever, redness, swelling, or drainage from the insertion site.
j. Report symptoms of fainting, nausea, weakness, blackouts, and rapid pulse rates to the PHCP.
k. During shock discharge, the client may feel faint or short of breath.
l. Instruct the client to sit or lie down if she or he feels a shock and to notify the PHCP.
m. Advise the client to maintain a log of the date, time, and activity preceding the shock; the symptoms preceding the shock; and postshock sensations.
n. Instruct the client and family in how to access the emergency medical system.
o. Encourage the family to learn CPR.
p. Instruct the client to avoid electromagnetic fields directly over the AICD, because they can inactivate the device.
q. Instruct the client to move away from the magnetic field immediately if beeping tones are heard, and to notify the PHCP.
r. Keep an AICD identification card in the wallet and obtain and wear a MedicAlert bracelet.
s. Inform all PHCPs that an AICD has been inserted; certain diagnostic tests, such as MRI, and procedures using diathermy or electrocautery interfere with AICD function.

VI. Pacemakers
A. Description: Temporary or permanent device that provides electrical stimulation and maintains the heart rate when the client’s intrinsic pacemaker fails to provide an adequate rate
B. Settings
1. A synchronous (demand) pacemaker senses the client’s rhythm and paces only if the client’s intrinsic rate falls below the set pacemaker rate for stimulating depolarization.
2. An asynchronous (fixed rate) pacemaker paces at a preset rate regardless of the client’s intrinsic rhythm
and is used when the client is asystolic or profoundly bradycardic.

3. Overdrive pacing suppresses the underlying rhythm in tachydysrhythmias so that the sinus node will regain control of the heart.

C. Spikes

1. When a pacing stimulus is delivered to the heart, a spike (straight vertical line) is seen on the monitor or ECG strip.
2. Spikes precede the chamber being paced; a spike preceding a P wave indicates that the atrium is paced, and a spike preceding the QRS complex indicates that the ventricle is being paced.
3. An atrial spike followed by a P wave indicates atrial depolarization, and a ventricular spike followed by a QRS complex represents ventricular depolarization; this is referred to as capture.

D. Temporary pacemakers

1. Noninvasive transcutaneous pacing
   a. Noninvasive transcutaneous pacing is used as a temporary emergency measure in the profoundly bradycardic or asystolic client until invasive pacing can be initiated.
   b. Large electrode pads are placed on the client’s chest and back and connected to an external pulse generator.
   c. Wash the skin with soap and water before applying electrodes.
   d. It is not necessary to shave the hair or apply alcohol or tinctures to the skin.
   e. Place the posterior electrode between the spine and left scapula behind the heart, avoiding placement over bone.
   f. Place the anterior electrode between V2 and V5 positions over the heart.
   g. Do not place the anterior electrode over female breast tissue; rather, displace breast tissue and place the electrode under the breast.
   h. Do not take the pulse or BP on the left side; the results will not be accurate because of the muscle twitching and electrical current.
   i. Ensure that electrodes are in good contact with the skin.
   j. Set pacing rate as prescribed; establish
stimulation threshold to ensure capture.
k. If loss of capture occurs, assess the skin contact of the electrodes and increase the current until capture is regained.
l. Evaluate the client for discomfort from cutaneous and muscle stimulation; administer analgesics as needed.

2. Invasive transvenous pacing
   a. Pacing lead wire is placed through the antecubital, femoral, jugular, or subclavian vein into the right atrium or right ventricle, so that it is in direct contact with the endocardium.
   b. Monitor the pacemaker insertion site.
   c. Restrict client movement to prevent lead wire displacement.

3. Invasive epicardial pacing—applied by using a transthoracic approach; the lead wires are threaded loosely on the epicardial surface of the heart after cardiac surgery.

4. Reducing the risk of microshock
   a. Use only inspected and approved equipment.
   b. Insulate the exposed portion of wires with plastic or rubber material (fingers of rubber gloves) when wires are not attached to the pulse generator; cover with nonconductive tape.
   c. Ground all electrical equipment, using a 3-pronged plug.
   d. Wear gloves when handling exposed wires.
   e. Keep dressings dry.

Vital signs are monitored and cardiac monitoring is done continuously for the client with a temporary pacemaker.

E. Permanent pacemakers
   1. Pulse generator is internal and surgically implanted in a subcutaneous pocket below the clavicle.
   2. The leads are passed transvenously via the cephalic or subclavian vein to the endocardium on the right side of the heart; postoperatively, limitation of arm movement on the operative side is required to
prevent lead wire dislodgement.

3. Permanent pacemakers may be single-chambered, in which the lead wire is placed in the chamber to be paced; or dual-chambered, with lead wires placed in both the right atrium and the right ventricle.

4. Biventricular pacing of the ventricles allows for synchronized depolarization and is used for moderate to severe heart failure to improve cardiac output.

5. A permanent pacemaker is programmed when inserted and can be reprogrammed if necessary by noninvasive transmission from an external programmer to the implanted generator.

6. Pacemakers may be powered by a lithium battery with an average life span of 10 years, nuclear-powered with a life span of 20 years or longer, or designed to be recharged externally.

7. Pacemaker function can be checked in the PHCP’s office or clinic by a pacemaker interrogator or programmer or from home, using a special telephone transmitter device.

8. The client may be provided with a device placed over the pacemaker battery generator with an attachment to the telephone; the heart rate then can be transmitted to the clinic.

9. Client teaching (Box 52-5).

VII. Coronary Artery Disease

A. Description

1. Coronary artery disease is a narrowing or obstruction of 1 or more coronary arteries as a result of atherosclerosis, which is an accumulation of lipid-containing plaque in the arteries (Fig. 52-11).

2. The disease causes decreased perfusion of myocardial tissue and inadequate myocardial oxygen supply, leading to hypertension, angina, dysrhythmias, MI, heart failure, and death.

3. Collateral circulation, more than 1 artery supplying a muscle with blood, is normally present in the coronary arteries, especially in older persons.

4. The development of collateral circulation takes time and develops when chronic ischemia occurs to meet the metabolic demands; therefore, an occlusion of a coronary artery in a younger individual is more likely to be lethal than one in an older individual.

5. Symptoms occur when the coronary artery is occluded to the point that inadequate blood supply to the muscle occurs, causing ischemia.

6. Coronary artery narrowing is significant if the lumen
diameter of the left main artery is reduced at least 50%, or if any major branch is reduced at least 75%.

7. The goal of treatment is to alter the atherosclerotic progression.

B. Assessment
   1. Possibly normal findings during asymptomatic periods
   2. Chest pain
   3. Palpitations
   4. Dyspnea
   5. Syncope
   6. Cough or hemoptysis
   7. Excessive fatigue

C. Diagnostic studies
   1. Electrocardiography
      a. When blood flow is reduced and ischemia occurs, ST-segment depression, T-wave inversion, or both is noted; the ST segment returns to normal when the blood flow returns.
      b. With infarction, cell injury results in ST-segment elevation, followed by T-wave inversion and an abnormal Q wave.
   2. Cardiac catheterization: Cardiac catheterization shows the presence of atherosclerotic lesions.
   3. Blood lipid levels
      a. Blood lipid levels may be elevated.
      b. Cholesterol-lowering medications may be prescribed to reduce the development of atherosclerotic plaques.

D. Interventions
   1. Assist the client to identify risk factors that can be modified and to set goals to promote lifestyle changes to reduce the impact of risk factors.
   2. Assist the client to identify barriers to adherence with the therapeutic plan and to identify methods to overcome barriers.
   3. Instruct the client regarding a low-calorie, low-sodium, low-cholesterol, and low-fat diet, with an increase in dietary fiber.
   4. Stress that dietary changes should be incorporated for the rest of the client’s life; instruct the client regarding prescribed medications.
   5. Provide community resources to the client regarding exercise, smoking cessation, and stress reduction as appropriate.
E. Surgical procedures

1. PTCA to compress the plaque against the walls of the artery and dilate the vessel
2. Laser angioplasty to vaporize the plaque
3. Atherectomy to remove the plaque from the artery
4. Vascular stent to prevent the artery from closing and to prevent restenosis
5. Coronary artery bypass grafting past the occluded artery to improve blood flow to the myocardial tissue at risk for ischemia or infarction

F. Medications

1. Nitrates to dilate the coronary arteries and decrease preload and afterload
2. Calcium channel blockers to dilate coronary arteries and reduce vasospasm
3. Cholesterol-lowering medications to reduce the development of atherosclerotic plaques
4. Beta blockers to reduce the BP in individuals who are hypertensive

VIII. Angina

A. Description

1. Angina is chest pain resulting from myocardial ischemia caused by inadequate myocardial blood and oxygen supply.
2. Angina is caused by an imbalance between oxygen supply and demand.
3. Causes include obstruction of coronary blood flow resulting from atherosclerosis, coronary artery spasm, or conditions increasing myocardial oxygen consumption.

The goal of treatment for angina is to provide relief from the acute attack, correct the imbalance between myocardial oxygen supply and demand, and prevent the progression of the disease and further attacks to reduce the risk of MI.

B. Patterns of angina

1. Stable angina
   a. Also called exertional angina
   b. Occurs with activities that involve exertion or emotional stress; relieved with rest or nitroglycerin
   c. Usually has a stable pattern of onset, duration, severity, and relieving factors
2. Unstable angina
   a. Also called preinfarction angina
b. Associated with worsening cardiac ischemia
c. Occurs with an unpredictable degree of exertion or emotion and increases in occurrence, duration, and severity over time
d. Lasts longer than 15 minutes
e. Pain may not be relieved with nitroglycerin.

3. Variant angina
a. Also called Prinzmetal’s or vasospastic angina
b. Results from coronary artery spasm
c. May occur at rest
d. Attacks may be associated with ST-segment elevation noted on the ECG.

4. Intractable angina is a chronic, incapacitating angina unresponsive to interventions.

C. Assessment

1. Pain
a. Pain can develop slowly or quickly.
b. Pain usually is described as mild or moderate.
c. Substernal, crushing, squeezing pain may occur.
d. Pain may radiate to the shoulders, arms, jaw, neck, or back.
e. Pain intensity is unaffected by inspiration and expiration.
f. Pain usually lasts less than 5 minutes; however, pain can last up to 15 to 20 minutes.
g. Pain is relieved by nitroglycerin or rest.

2. Dyspnea
3. Pallor
4. Sweating
5. Palpitations and tachycardia
6. Dizziness and syncope
7. Hypertension
8. Digestive disturbances

D. Diagnostic studies

1. Electrocardiography: Readings are normal during rest, with ST depression or T-wave inversion during an episode of pain.
2. Stress testing: Chest pain or changes in the ECG or
vital signs during testing may indicate ischemia.
3. Troponin and cardiac enzyme levels: Findings are normal in angina.
4. Cardiac catheterization: Provides a definitive diagnosis by providing information about the patency of the coronary arteries.

E. Interventions

1. Immediate management
   a. Assess pain; institute pain relief measures.
   b. Administer oxygen by nasal cannula as prescribed.
   c. Assess vital signs and provide continuous cardiac monitoring and nitroglycerin as prescribed to dilate the coronary arteries, reduce the oxygen requirements of the myocardium, and relieve the chest pain.
   d. Ensure that bed rest is maintained, place the client in semi-Fowler’s position, and stay with the client.
   e. Obtain a 12-lead ECG.
   f. Establish an IV access route.

2. Following the acute episode
   a. See section VII, D (Coronary Artery Disease, Interventions).
   b. Assist the client to identify angina-precipitating events.
   c. Instruct the client to stop activity and rest if chest pain occurs; sit down and take nitroglycerin as prescribed; the client is usually instructed to call emergency medical services if the nitroglycerin does not relieve the pain, and many PHCPs recommend that the client also chew an aspirin.

F. Surgical procedures: See section VII, E (Coronary Artery Disease, Surgical procedures).

G. Medications

1. See section VII, F (Coronary Artery Disease, Medications).
2. Antiplatelet therapy may be prescribed to inhibit platelet aggregation and reduce the risk of developing an acute MI.

IX. Myocardial Infarction
A. Description

1. MI occurs when myocardial tissue is abruptly and severely deprived of oxygen.
2. Ischemia can lead to necrosis of myocardial tissue if blood flow is not restored.
3. Infarction does not occur instantly but evolves over several hours.
4. Obvious physical changes do not occur in the heart until 6 hours after the infarction, when the infarcted area appears blue and swollen.
5. After 48 hours, the infarct turns gray, with yellow streaks developing as neutrophils invade the tissue.
6. By 8 to 10 days after infarction, granulation tissue forms.
7. Over 2 to 3 months, the necrotic area develops into a scar; scar tissue permanently changes the size and shape of the ventricle.
8. Not all clients experience the classic symptoms of an MI.
9. Women may experience atypical discomfort, shortness of breath, or fatigue and often present with non–ST-elevation myocardial infarction (NSTEMI) or T-wave inversion.
10. An older client may experience shortness of breath, pulmonary edema, dizziness, altered mental status, or a dysrhythmia.

B. Location of MI (see Fig. 52-1)

1. Obstruction of the LAD artery results in anterior wall or septal MI, or both.
2. Obstruction of the circumflex artery results in posterior wall MI or lateral wall MI.
3. Obstruction of the right coronary artery results in inferior wall MI.

C. Risk factors

1. Atherosclerosis
2. Coronary artery disease
3. Elevated cholesterol levels
4. Smoking
5. Hypertension
6. Obesity
7. Physical inactivity
8. Impaired glucose tolerance
9. Stress

D. Diagnostic studies
1. Troponin level: Level rises within 3 hours and remains elevated for up to 7 to 10 days.
2. Total CK level: Level rises within 6 hours after the onset of chest pain and peaks within 18 hours after damage and death of cardiac tissue.
3. CK-MB isoenzyme: Peak elevation occurs 18 hours after the onset of chest pain and returns to normal 48 to 72 hours later.
4. Myoglobin: Level rises within 2 hours after cell death, with a rapid decline in the level after 7 hours.
5. White blood cell count: An elevated white blood cell count appears on the second day following the MI and lasts up to 1 week.
6. Electrocardiogram
   a. ECG shows either ST segment elevation MI (STEMI), T-wave inversion, or NSTEMI; an abnormal Q wave may also present.
   b. Hours to days after the MI, ST- and T-wave changes will return to normal, but the Q-wave changes usually remain permanently.
7. Cardiac catheterization may be done emergently to determine the extent and location of obstructions of the coronary arteries; this allows for use of PTCA and restoration of bloodflow to the myocardium.
8. Diagnostic tests following the acute stage
   a. Exercise tolerance test or stress test to assess for electrocardiographic changes and ischemia and to evaluate for medical therapy or identify clients who may need invasive therapy.
   b. Thallium scans to assess for ischemia or necrotic muscle tissue.
   c. Multigated cardiac blood pool imaging scans may be used to evaluate left ventricular function.
   d. If not done urgently, cardiac catheterization to determine the coronary artery obstructions will be done after the client is stabilized.

E. Assessment

1. Pain
   a. Client may experience crushing substernal pain.
   b. Pain may radiate to the jaw, back, and left arm.
c. Pain may occur without cause, primarily early in the morning.
d. Pain is unrelieved by rest or nitroglycerin and is relieved only by opioids.
e. Pain lasts 30 minutes or longer.

2. Nausea and vomiting
3. Diaphoresis
4. Dyspnea
5. Dysrhythmias
6. Feelings of fear and anxiety, impending doom
7. Pallor, cyanosis, coolness of extremities

F. Complications of MI (Box 52-6)

G. Interventions, acute stage

Pain relief increases oxygen supply to the myocardium; administer morphine as a priority in managing pain in the client having an MI.

1. Obtain a description of the chest discomfort.
2. Administer oxygen and institute pain relief measures (morphine, nitroglycerin as prescribed).
3. Assess vital signs and cardiovascular status and maintain cardiac monitoring.
4. Assess respiratory rate and breath sounds for signs of heart failure, as indicated by the presence of crackles or wheezes or dependent edema.
5. Ensure bed rest and place the client in a semi-Fowler’s position to enhance comfort and tissue oxygenation; stay with the client.
6. Establish an IV access route.
7. Obtain a 12-lead ECG.
8. Monitor laboratory values.
9. Monitor for cardiac dysrhythmias, because tachycardia and PVCs frequently occur in the first few hours after MI; administer antidysrhythmics as prescribed.
10. Administer thrombolytic therapy, which may be prescribed within the first 6 hours of the coronary event if cardiac catheterization is not to be done emergently; monitor for signs of bleeding if the client is receiving thrombolytic therapy.
11. Assess distal peripheral pulses and skin temperature, because poor cardiac output may be identified by cool diaphoretic skin and diminished or absent pulses.
12. Monitor the BP closely after the administration of medications; if the systolic pressure is lower than
100 mm Hg or 25 mm Hg lower than the previous reading, lower the head of the bed and notify the PHCP.

13. Administer beta blockers as prescribed to slow the heart rate and increase myocardial perfusion while reducing the force of myocardial contraction.

14. Provide reassurance to the client and family.

H. Interventions following the acute episode

1. Maintain bed rest as prescribed.
2. Allow the client to stand to void or use a bedside commode if prescribed.
3. Provide range-of-motion exercises to prevent thrombus formation and maintain muscle strength.
4. Progress to dangling legs at the side of the bed or out of bed to the chair for 30 minutes 3 times a day as prescribed.
5. Progress to ambulation in the client’s room and to the bathroom and then in the hallway 3 times a day.
7. Administer angiotensin-converting enzyme (ACE) inhibitors, angiotensin-II receptor blockers (ARBs), calcium channel blockers, aspirin, thienopyridines (clopidogrel), and lipid-lowering agents as prescribed.
8. Encourage the client to verbalize feelings regarding the MI.

I. Cardiac rehabilitation: Process of actively assisting the client with cardiac disease to achieve and maintain a vital and productive life within the limitations of the heart disease; also refer to section VII, D (Coronary Artery Disease, Interventions).

X. Heart Failure

A. Description

1. Heart failure is the inability of the heart to maintain adequate cardiac output to meet the metabolic needs of the body because of impaired pumping ability.
2. Diminished cardiac output results in inadequate peripheral tissue perfusion.
3. Congestion of the lungs and periphery may occur; the client can develop acute pulmonary edema.

B. Classification

1. Acute heart failure occurs suddenly.
2. Chronic heart failure develops over time; however, a client with chronic heart failure can develop an acute episode.

C. Types of heart failure

1. Right ventricular failure, left ventricular failure
a. Because the 2 ventricles of the heart represent 2 separate pumping systems, it is possible for 1 to fail alone for a short period.
b. Most heart failure begins with left ventricular failure and progresses to failure of both ventricles.
c. Acute pulmonary edema, a medical emergency, results from left ventricular failure.
d. If pulmonary edema is not treated, death will occur from suffocation because the client literally drowns in her or his own fluids.

2. Forward failure, backward failure
   a. In forward failure, an inadequate output of the affected ventricle causes decreased perfusion to vital organs.
   b. In backward failure, blood backs up behind the affected ventricle, causing increased pressure in the atrium behind the affected ventricle.

3. Low output, high output
   a. In low-output failure, not enough cardiac output is available to meet the demands of the body.
   b. High-output failure occurs when a condition causes the heart to work harder to meet the demands of the body.

4. Systolic failure, diastolic failure
   a. Systolic failure, also known as heart failure with reduced ejection fraction (HFrEF), leads to problems with contraction and ejection of blood.
   b. Diastolic failure, also known as heart failure with preserved ejection fraction (HFpEF), leads to problems with the heart relaxing and filling with blood.

D. Compensatory mechanisms
   1. Compensatory mechanisms act to restore cardiac output to near-normal levels.
   2. Initially, these mechanisms increase cardiac output; however, they eventually have a damaging effect on pump action.
   3. Compensatory mechanisms contribute to an increase in myocardial oxygen consumption; when this occurs,
myocardial reserve is exhausted and clinical manifestations of heart failure develop.

4. Compensatory mechanisms include increased heart rate, improved stroke volume, arterial vasoconstriction, sodium and water retention, and myocardial hypertrophy.

E. Assessment (Table 52-1)

1. Right- and left-sided heart failure
2. Acute pulmonary edema
   a. Severe dyspnea
   b. Tachycardia, tachypnea
   c. Nasal flaring; use of accessory breathing muscles
   d. Wheezing and crackles on auscultation; gurgling respirations
   e. Expectoration of large amounts of blood-tinged, frothy sputum
   f. Acute anxiety, apprehension, restlessness
   g. Profuse sweating
   h. Cold, clammy skin
   i. Cyanosis

Signs of left ventricular failure are evident in the pulmonary system. Signs of right ventricular failure are evident in the systemic circulation.

F. Immediate management of acute episode (see Priority Nursing Actions)

G. Following the acute episode

1. Assist the client to identify precipitating risk factors of heart failure and methods of eliminating these risk factors.
2. Encourage the client to verbalize feelings about the lifestyle changes required as a result of the heart failure.
3. Instruct the client in the prescribed medication regimen, which may include digoxin, a diuretic, ACE inhibitors, low-dose beta blockers, and vasodilators.
4. Advise the client to notify the PHCP if side effects occur from the medications.
5. Advise the client to avoid over-the-counter medications.
6. Instruct the client to contact the PHCP if she or he is unable to take medications because of illness.
7. Instruct the client to avoid large amounts of caffeine, found in coffee, tea, cocoa, chocolate, and some carbonated beverages.

8. Instruct the client about the prescribed low-sodium, low-fat, and low-cholesterol diet.

9. Provide the client with a list of potassium-rich foods, because diuretics can cause hypokalemia (except for potassium-retaining diuretics).

10. Instruct the client regarding fluid restriction, if prescribed, advising the client to spread the fluid out during the day and to suck on hard candy to reduce thirst.

11. Instruct the client to balance periods of activity and rest.

12. Advise the client to avoid isometric activities, which increase pressure in the heart.

13. Instruct the client to monitor daily weight.

14. Instruct the client to report signs of fluid retention such as edema or weight gain.

XI. See Chapter 69 for a discussion on cardiogenic shock and associated invasive monitoring.

XII. Inflammatory Diseases of the Heart

A. Pericarditis

1. Description

   a. Pericarditis is an acute or chronic inflammation of the pericardium.
   b. Chronic pericarditis, a chronic inflammatory thickening of the pericardium, constricts the heart, causing compression.
   c. The pericardial sac becomes inflamed.
   d. Pericarditis can result in loss of pericardial elasticity or an accumulation of fluid within the sac.
   e. Heart failure or cardiac tamponade may result.

2. Assessment

   a. Pain in the anterior chest that radiates to the left side of the neck, shoulder, or back
   b. Pain is grating and is aggravated by breathing (particularly inspiration), coughing, and swallowing
   c. Pain is worse when in the supine position.
position and may be relieved by leaning forward.
d. Pericardial friction rub (scratchy, high-pitched sound) is heard on auscultation and is produced by the rubbing of the inflamed pericardial layers.
e. Fever and chills
f. Fatigue and malaise
g. Elevated white blood cell count
h. Electrocardiographic changes with acute pericarditis; ST-segment elevation with the onset of inflammation; atrial fibrillation is common.
i. Signs of right ventricular failure in clients with chronic constrictive pericarditis

3. Interventions
a. Assess the nature of the pain.
   b. Place the client in a high-Fowler’s position, or upright and leaning forward.
c. Administer oxygen.
d. Administer analgesics, nonsteroidal anti-inflammatory drugs (NSAIDs), or corticosteroids for pain as prescribed.
e. Auscultate for a pericardial friction rub.
f. Check results of blood culture to identify the causative organism.
g. Administer antibiotics for bacterial infection as prescribed.
h. Administer diuretics and digoxin as prescribed to the client with chronic constrictive pericarditis; surgical incision of the pericardium (pericardial window) or pericardiectomy may be necessary.
i. Monitor for signs of cardiac tamponade.
j. Notify the PHCP if signs of cardiac tamponade occur.

B. Myocarditis
1. Description: Acute or chronic inflammation of the myocardium as a result of pericarditis, systemic
infection, or allergic response

2. Assessment
   a. Fever
   b. Dyspnea
   c. Tachycardia
   d. Chest pain
   e. Pericardial friction rub
   f. Gallop rhythm
   g. Murmur that sounds like fluid passing an obstruction
   h. Pulsus alternans
   i. Signs of heart failure

3. Interventions
   a. Assist the client to a position of comfort, such as sitting up and leaning forward.
   b. Administer oxygen as prescribed.
   c. Administer analgesics, salicylates, and NSAIDs as prescribed to reduce fever and pain.
   d. Administer digoxin as prescribed.
   e. Administer antidysrhythmics as prescribed.
   f. Administer antibiotics as prescribed to treat the causative organism.
   g. Monitor for complications, which can include thrombus, heart failure, and cardiomyopathy.

C. Endocarditis

1. Description
   a. Endocarditis is an inflammation of the inner lining of the heart and valves.
   b. Occurs primarily in clients who are IV drug users, have had valve replacements or repair of valves with prosthetic materials, or have other structural cardiac defects.
   c. Ports of entry for the infecting organism include the oral cavity (especially if the client has had a dental procedure in the previous 3 to 6 months), infections (cutaneous, genitourinary, gastrointestinal, and systemic), and surgery or invasive procedures, including IV line placement.

2. Assessment
   a. Fever
   b. Anorexia, weight loss
c. Fatigue
d. Cardiac murmurs
e. Heart failure
f. Embolic complications from vegetation fragments traveling through the arterial circulation
g. Petechiae
h. Splinter hemorrhages in the nailbeds
i. Osler’s nodes (reddish, tender lesions) on the pads of the fingers, hands, and toes
j. Janeway lesions (nontender hemorrhagic lesions) on the fingers, toes, nose, or earlobes
k. Splenomegaly
l. Clubbing of the fingers

3. Interventions
a. Provide adequate rest balanced with activity to prevent thrombus formation.
b. Monitor for signs of heart failure.
c. Monitor for splenic emboli, as evidenced by sudden abdominal pain radiating to the left shoulder and the presence of rebound abdominal tenderness on palpation.
d. Monitor for renal emboli, as evidenced by flank pain radiating to the groin, hematuria, and pyuria.
e. Monitor for confusion, aphasia, or dysphasia, which may indicate central nervous system emboli.
f. Monitor for pulmonary emboli as evidenced by pleuritic chest pain, dyspnea, and cough.
g. Assess skin, mucous membranes, and conjunctiva for petechiae.
h. Assess nailbeds for splinter hemorrhages.
i. Assess for Osler’s nodes on the pads of the fingers, hands, and toes.
j. Assess for Janeway lesions on the fingers, toes, nose, or earlobes.
k. Assess for clubbing of the fingers.
l. Evaluate blood culture results.
m. Administer antibiotics intravenously as prescribed.
n. Plan and arrange for discharge,
providing resources required for the continued administration of IV antibiotics.

4. Client education (Box 52-7)

XIII. Cardiac Tamponade

A. Description

1. A pericardial effusion occurs when the space between the parietal and visceral layers of the pericardium fills with fluid.
2. Pericardial effusion places the client at risk for cardiac tamponade, an accumulation of fluid in the pericardial cavity.
3. Tamponade restricts ventricular filling, and cardiac output drops.

Acute cardiac tamponade can occur when small volumes (20 to 50 mL) of fluid accumulate rapidly in the pericardium.

B. Assessment

1. Pulsus paradoxus
2. Increased CVP
3. Jugular venous distention with clear lungs
4. Distant, muffled heart sounds
5. Decreased cardiac output
6. Narrowing pulse pressure

C. Interventions

1. The client needs to be placed in a critical care unit for hemodynamic monitoring.
2. Administer fluids intravenously as prescribed to manage decreased cardiac output.
3. Prepare the client for chest x-ray or echocardiography.
4. Prepare the client for pericardiocentesis to withdraw pericardial fluid if prescribed.
5. Monitor for recurrence of tamponade following pericardiocentesis.
6. If the client experiences recurrent tamponade or recurrent effusions or develops adhesions from chronic pericarditis, a portion (pericardial window) or all of the pericardium (pericardiectomy) may be removed to allow adequate ventricular filling and contraction.

XIV. Valvular Heart Disease

A. Description
1. Valvular heart disease occurs when the heart valves cannot open fully (stenosis) or close completely (insufficiency or regurgitation).
2. Valvular heart disease prevents efficient blood flow through the heart.

B. Types

1. Mitral stenosis: Valvular tissue thickens and narrows the valve opening, preventing blood from flowing from the left atrium to the left ventricle.
2. Mitral insufficiency, regurgitation: Valve is incompetent, preventing complete valve closure during systole.
3. Mitral valve prolapse: Valve leaflets protrude into the left atrium during systole.
4. Aortic stenosis: Valvular tissue thickens and narrows the valve opening, preventing blood from flowing from the left ventricle into the aorta.
5. Aortic insufficiency: Valve is incompetent, preventing complete valve closure during diastole.
6. For aortic disorders, see Table 52-2.
7. For tricuspid disorders, see Table 52-3.
8. For pulmonary valve disorders, see Table 52-4.

C. Repair procedures

1. Percutaneous balloon valvuloplasty
   a. A balloon catheter is passed from the femoral vein through the atrial septum to the mitral valve or through the femoral artery to the aortic valve.
   b. The balloon is inflated to enlarge the orifice.
   c. Monitor for bleeding from the catheter insertion site.
   d. Institute precautions for arterial puncture if appropriate; site care and monitoring is similar to that after cardiac catheterization.
   e. Monitor for signs of systemic emboli.
   f. Monitor for signs of a regurgitant valve by monitoring cardiac rhythm, heart sounds, and cardiac output.
2. Mitral annuloplasty: Tightening and suturing the malfunctioning valve annulus to eliminate or greatly reduce regurgitation; percutaneous or open surgical approach.
3. Commissurotomy, valvotomy
   a. Thrombi are removed and calcium deposits are debrided; the valve is incised and widened.
b. Percutaneous route or open heart surgical approach.

D. Valve replacement procedures
   1. Mechanical prosthetic valves: These prosthetic valves are durable
   2. Risk of clot formation is high as the body reacts to the artificial materials; anticoagulation is required.

   Thromboembolism can be a problem following valve replacement with a mechanical prosthetic valve, and lifetime anticoagulant therapy is required.

   3. Bioprosthetic valves
      a. Biological grafts are xenografts (valves from other species)—porcine valves (pig), bovine valves (cow), or homografts (human cadavers). These valves are less durable than mechanical prosthetic valves.
      b. The risk of clot formation is small; therefore, long-term anticoagulation may not be indicated.

   4. Open heart surgical approach.
   5. Preoperative interventions: Consult with the PHCP regarding discontinuing anticoagulants 72 hours before surgery.

   6. Postoperative interventions
      a. Monitor closely for signs of bleeding.
      b. Monitor cardiac output and for signs of heart failure.
      c. Administer digoxin as prescribed to maintain cardiac output and prevent atrial fibrillation.
      d. Client education (Box 52-8).

XV. Cardiomyopathy (Table 52-5)
   A. Description
      1. Cardiomyopathy is a subacute or chronic disorder of the heart muscle.
      2. Treatment is palliative, not curative, and the client needs to deal with numerous lifestyle changes and a shortened life span.

   B. Types, signs and symptoms, and treatment (see Table 52-5)

XVI. Vascular Disorders
   A. Venous thrombosis
      1. Description
a. Thrombus can be associated with an inflammatory process.
b. When a thrombus develops, inflammation occurs, thickening the vein wall and leading to embolization.

2. Types

a. Thrombophlebitis: Thrombus associated with vein inflammation
b. Phlebothrombosis: Thrombus without vein inflammation
c. Phlebitis: Vein inflammation associated with invasive procedures, such as IV lines
d. Deep vein thrombophlebitis: More serious than a superficial thrombophlebitis because of the risk for pulmonary embolism

3. Risk factors for thrombus formation

a. Venous stasis from varicose veins, heart failure, immobility
b. Hypercoagulability disorders
c. Injury to the venous wall from IV injections; administration of vessel irritants (chemotherapy, hypertonic solutions)
d. Following surgery, particularly orthopedic and abdominal surgery
e. Pregnancy
f. Ulcerative colitis
g. Use of oral contraceptives
h. Certain malignancies
i. Fractures or other injuries of the pelvis or lower extremities

B. Phlebitis

1. Assessment

a. Red, warm area radiating up the vein and extremity
b. Pain
c. Swelling

2. Interventions

a. Apply warm, moist soaks as prescribed to dilate the vein and promote circulation (assess temperature of soak before applying).
b. Assess for signs of complications such
as tissue necrosis, infection, or pulmonary embolus.

C. Deep vein thrombophlebitis

1. Assessment
   a. Calf or groin tenderness or pain with or without swelling
   b. Positive Homans’ sign may be noted; however, false-positive results are common, so this is not a reliable assessment measure.
   c. Warm skin that is tender to touch

2. Interventions
   a. Provide bed rest as prescribed.
   b. Elevate the affected extremity above the level of the heart as prescribed.
   c. Avoid using the knee gatch or a pillow under the knees.
   d. Do not massage the extremity.
   e. Provide thigh-high or knee-high antiembolism stockings as prescribed to reduce venous stasis and assist in the venous return of blood to the heart; teach how to apply and remove stockings.
   f. Administer intermittent or continuous warm, moist compresses as prescribed.
   g. Palpate the site gently, monitoring for warmth and edema.
   h. Measure and record the circumferences of the thighs and calves.
   i. Monitor for shortness of breath and chest pain, which can indicate pulmonary emboli.
   j. Administer thrombolytic therapy (tissue plasminogen activator) if prescribed, which must be initiated within 5 days after the onset of symptoms.
   k. Administer heparin therapy as prescribed to prevent enlargement of the existing clot and prevent the formation of new clots.
   l. Monitor activated partial thromboplastin time during heparin therapy.
   m. Administer warfarin as prescribed following heparin therapy when the symptoms of deep vein
D. Venous insufficiency

1. Description

a. Venous insufficiency results from prolonged venous hypertension, which stretches the veins and damages the valves.
b. The resultant edema and venous stasis cause venous stasis ulcers, swelling, and cellulitis.
c. Treatment focuses on decreasing edema and promoting venous return from the affected extremity.
d. Treatment for venous stasis ulcers focuses on healing the ulcer and preventing stasis and ulcer recurrence.

2. Assessment

a. Stasis dermatitis or brown discoloration along the ankles, extending up to the calf
b. Edema
c. Ulcer formation: Edges are uneven, ulcer bed is pink, and granulation is present; usually located on the lateral malleolus.

3. Interventions

For venous insufficiency, leg elevation is usually prescribed to assist with the return of blood to the heart.

a. Instruct the client to wear elastic or compression stockings during the day and evening if prescribed (instruct the client to put on elastic stockings on awakening, before getting out of bed); it may be necessary to wear the stockings for the remainder of the client’s life.
b. Instruct the client to avoid prolonged
sitting or standing, constrictive clothing, or crossing the legs when seated.
c. Instruct the client to elevate the legs above the level of the heart for 10 to 20 minutes every few hours each day.
d. Instruct the client in the use of an intermittent sequential pneumatic compression system, if prescribed (used twice daily for 1 hour in the morning and evening).
e. Advise the client with an open ulcer that the compression system is applied over a dressing.

4. Wound care
   a. Provide care to the wound as prescribed.
   b. Assess the client’s ability to care for the wound, and initiate home care resources as necessary.
   c. If an Unna boot (dressing constructed of gauze moistened with zinc oxide) is prescribed, the PHCP will change it weekly.
   d. The wound is cleansed with normal saline before application of the Unna boot; povidone-iodine and hydrogen peroxide are not used, because they destroy granulation tissue.
   e. The Unna boot is covered with an elastic wrap that hardens to promote venous return and prevent stasis.
   f. Monitor for signs of arterial occlusion from an Unna boot that may be too tight.
   g. Keep tape off the client’s skin.
   h. Occlusive dressings such as polyethylene film or a hydrocolloid dressing may be used to cover the ulcer.

5. Medications
   a. Apply topical agents to the wound as prescribed to debride the ulcer, eliminate necrotic tissue, and promote healing.
   b. When applying topical debriding agents, apply an oil-based agent such as petroleum jelly on surrounding skin
to protect healthy tissue.
c. Administer antibiotics as prescribed if infection or cellulitis occurs.

E. Varicose veins

1. Description
   a. Distended, protruding veins that appear darkened and tortuous.
   b. Vein walls weaken and dilate, and valves become incompetent.

2. Assessment
   a. Pain in the legs with dull aching after standing
   b. A feeling of fullness in the legs
   c. Ankle edema

3. Trendelenburg’s test
   a. Place the client in a supine position with the legs elevated.
   b. When the client sits up, if varicosities are present, veins fill from the proximal end; veins normally fill from the distal end.

4. Interventions
   a. Emphasize the importance of antiembolism stockings as prescribed.
   b. Instruct the client to elevate the legs as much as possible.
   c. Instruct the client to avoid constrictive clothing and pressure on the legs.
   d. Prepare the client for sclerotherapy or vein stripping as prescribed.

5. Sclerotherapy
   a. A solution is injected into the vein, followed by the application of a pressure dressing.
   b. Incision and drainage of the trapped blood in the sclerosed vein is performed 14 to 21 days after the injection, followed by the application of a pressure dressing for 12 to 18 hours.

6. Laser therapy: A laser fiber is used to heat and close the main vessel contributing to the varicosity.

7. Vein stripping: Varicose veins may be removed if they are larger than 4 mm in diameter or if they are in clusters; other treatments are usually tried before vein
A. Peripheral arterial disease

1. Description
   a. Chronic disorder in which partial or total arterial occlusion deprives the lower extremities of oxygen and nutrients
   b. Tissue damage occurs below the level of the arterial occlusion.
   c. Atherosclerosis is the most common cause of peripheral arterial disease.

2. Assessment
   a. Intermittent claudication (pain in the muscles resulting from an inadequate blood supply)
   b. Rest pain, characterized by numbness, burning, or aching in the distal portion of the lower extremities, which awakens the client at night and is relieved by placing the extremity in a dependent position
   c. Lower back or buttock discomfort
   d. Loss of hair and dry scaly skin on the lower extremities
   e. Thickened toenails
   f. Cold and gray-blue color of skin in the lower extremities
   g. Elevational pallor and dependent rubor in the lower extremities
   h. Decreased or absent peripheral pulses
   i. Signs of arterial ulcer formation occurring on or between the toes or on the upper aspect of the foot that are characterized as painful
   j. BP measurements at the thigh, calf, and ankle are lower than the brachial pressure (normally, BP readings in the thigh and calf are higher than those in the upper extremities).

3. Interventions

   Because swelling in the extremities prevents arterial blood flow, the client with peripheral arterial disease is instructed to elevate
the feet at rest but to refrain from elevating them above the level of the heart, because extreme elevation slows arterial blood flow to the feet. In severe cases of peripheral arterial disease, clients with edema may sleep with the affected limb hanging from the bed, or they may sit upright (without leg elevation) in a chair for comfort.

a. Assess pain.
b. Monitor the extremities for color, motion and sensation, and pulses.
c. Obtain BP measurements.
d. Assess for signs of ulcer formation or signs of gangrene.
e. Assist in developing an individualized exercise program, which is initiated gradually and increased slowly to improve arterial flow through the development of collateral circulation.
f. Instruct the client to walk to the point of claudication pain, stop and rest, and then walk a little farther.
g. Instruct the client with peripheral arterial disease to avoid crossing the legs, which interferes with blood flow.
h. Instruct the client to avoid exposure to cold (causes vasoconstriction) to the extremities and to wear socks or insulated shoes for warmth at all times.
i. Instruct the client never to apply direct heat to the limb, such as with a heating pad or hot water, because the decreased sensitivity in the limb can cause burning.
j. Instruct the client to inspect the skin on the extremities daily and to report any signs of skin breakdown.
k. Instruct the client to avoid tobacco and caffeine because of their vasoconstrictive effects.
l. Instruct the client in the use of hemorheological and antiplatelet medications as prescribed.

4. Procedures to improve arterial blood flow
   a. Percutaneous transluminal angioplasty, with or without intravascular stent
   b. Laser-assisted angioplasty
   c. Atherectomy
   d. Peripheral arterial bypass surgery: Graft material is sutured above and below the occlusion to facilitate blood
flow around the occlusion. Inflow procedures bypass the occlusion above the superficial femoral arteries and include aortoiliac, aortofemoral, and axillofemoral bypasses; outflow procedures bypass the occlusion at or below the superficial femoral arteries and include femoropopliteal and femorotibial bypass (Fig. 52-12).

5. Preoperative interventions
   a. Assess baseline vital signs and peripheral pulses.
   b. Insert an IV line and urinary catheter as prescribed.
   c. Maintain a central venous catheter and/or arterial line if inserted.

6. Postoperative interventions
   a. Assess vital signs and notify the PHCP if changes occur.
   b. Monitor for hypotension, which may indicate hypovolemia.
   c. Monitor for hypertension, which may place stress on the graft and cause clot formation.
   d. Maintain bed rest for 24 hours as prescribed.
   e. Instruct the client to keep the affected extremity straight, limit movement, and avoid bending the knee and hip.
   f. Monitor for warmth, redness, and edema, which often are expected outcomes because of increased blood flow.
   g. Monitor for vessel or graft occlusion, which often occurs within the first 24 hours.
   h. Assess peripheral pulses and for adverse changes in color and temperature of the extremity.
   i. Assess the incision for drainage, warmth, or swelling.
   j. Monitor for excessive bleeding (a small amount of bloody drainage is expected).
   k. Monitor the area over the graft for hardness, tenderness, and warmth, which may indicate infection; if this occurs, notify the PHCP immediately.
1. Instruct the client about proper foot care and measures to prevent ulcer formation.

m. Assist the client in modifying lifestyle to prevent further plaque formation.

n. Following arterial revascularization, monitor for a sharp increase in pain, because pain is frequently the first indicator of postoperative graft occlusion. If signs of graft occlusion occur, notify the PHCP immediately.

B. Raynaud’s disease

1. Description
   a. Raynaud’s disease is vasospasm of the arterioles and arteries of the upper and lower extremities.
   b. Vasospasm causes constriction of the cutaneous vessels.
   c. Attacks occur with exposure to cold or stress.
   d. Affects primarily fingers, toes, ears, and cheeks.

2. Assessment
   a. Blanching of the extremity, followed by cyanosis from vasoconstriction
   b. Reddened tissue when the vasospasm is relieved
   c. Numbness, tingling, swelling, and a cold temperature at the affected body part

3. Interventions
   a. Monitor pulses.
   b. Administer vasodilators as prescribed.
   c. Instruct the client regarding medication therapy.
   d. Assist the client to identify and avoid precipitating factors such as cold and stress.
   e. Instruct the client to avoid smoking.
   f. Instruct the client to wear warm clothing, socks, and gloves in cold weather.
   g. Advise the client to avoid injuries to fingers and hands.

C. Buerger’s disease (thromboangiitis obliterans)
1. Description
   a. Buerger’s disease is an occlusive disease of the median and small arteries and veins.
   b. The distal upper and lower limbs are affected most commonly.

2. Assessment
   a. Intermittent claudication
   b. Ischemic pain occurring in the digits while at rest
   c. Aching pain that is more severe at night
   d. Cool, numb, or tingling sensation
   e. Diminished pulses in the distal extremities
   f. Extremities that are cool and red in the dependent position
   g. Development of ulcerations in the extremities

3. Interventions: See Raynaud’s disease

XVIII. Aortic Aneurysms
   A. Description
   1. An aortic aneurysm is an abnormal dilation of the arterial wall caused by localized weakness and stretching in the medial layer or wall of the aorta.
   2. The aneurysm can be located anywhere along the abdominal aorta.
   3. The goal of treatment is to limit the progression of the disease by modifying risk factors, controlling the BP to prevent strain on the aneurysm, recognizing symptoms early, and preventing rupture.

   B. Types of aortic aneurysm
   1. Fusiform: Diffuse dilation that involves the entire circumference of the arterial segment
   2. Saccular: Distinct localized outpouching of the artery wall
   3. Dissecting: Created when blood separates the layers of the artery wall, forming a cavity between them
   4. False (pseudoaneurysm): Occurs when the clot and connective tissue are outside the arterial wall as a result of vessel injury or trauma to all 3 layers of the arterial wall.

   C. Assessment
   1. Thoracic aneurysm
      a. Pain extending to neck, shoulders, lower back, or abdomen
      b. Syncope
      c. Dyspnea
d. Increased pulse  
e. Cyanosis  
f. Hoarseness, difficulty swallowing because of pressure from the aneurysm

2. Abdominal aneurysm  
a. Prominent, pulsating mass in abdomen, at or above the umbilicus  
b. Systolic bruit over the aorta  
c. Tenderness on deep palpation  
d. Abdominal or lower back pain

3. Rupturing aneurysm  
a. Severe abdominal or back pain  
b. Lumbar pain radiating to the flank and groin  
c. Hypotension  
d. Increased pulse rate  
e. Signs of shock  
f. Hematoma at flank area

4. Diagnostic tests  
a. Diagnostic tests are done to confirm the presence, size, and location of the aneurysm.  
b. Tests include abdominal ultrasound, computed tomography scan, and arteriography.

5. Interventions  
a. Monitor vital signs.  
b. Obtain information regarding back or abdominal pain.  
c. Question the client regarding the sensation of pulsation in the abdomen.  
d. Check peripheral circulation, including pulses, temperature, and color.  
e. Observe for signs of rupture.  
f. Note any tenderness over the abdomen.  
g. Monitor for abdominal distention.

6. Nonsurgical interventions  
a. Modify risk factors.  
b. Instruct the client regarding the procedure for monitoring BP.  
c. Instruct the client on the importance of regular PHCP visits to follow the size of the aneurysm.  
d. Instruct the client that if severe back or abdominal pain or fullness, soreness over the umbilicus, sudden development of discoloration in the
extremities, or a persistent elevation of BP occurs, to notify the PHCP immediately.

**Instruct the client with an aortic aneurysm to report immediately the occurrence of chest or back pain, shortness of breath, difficulty swallowing, or hoarseness.**

D. Pharmacological interventions
1. Administer antihypertensives to maintain the BP within normal limits and to prevent strain on the aneurysm.
2. Instruct the client about the purpose of the medications.
3. Instruct the client about the side effects and schedule of the medication.

E. Abdominal aortic aneurysm resection
1. Description: Surgical resection or excision of the aneurysm; the excised section is replaced with a graft that is sewn end to end (Fig. 52-13).
2. Preoperative interventions
   a. Assess all peripheral pulses as a baseline for postoperative comparison.
   b. Instruct the client in coughing and deep-breathing exercises.
3. Postoperative interventions
   a. Monitor vital signs.
   b. Monitor peripheral pulses distal to the graft site.
   c. Monitor for signs of graft occlusion, including changes in pulses, cool to cold extremities below the graft, white or blue extremities or flanks, severe pain, or abdominal distention.
   d. Limit elevation of the head of the bed to 45 degrees to prevent flexion of the graft.
   e. Monitor for hypovolemia and kidney failure resulting from significant blood loss during surgery.
   f. Monitor urine output hourly, and notify the PHCP if it is lower than 30 to 50 mL/hr.
   g. Monitor serum creatinine and blood urea nitrogen levels daily.
   h. Monitor respiratory status and
auscultate breath sounds to identify respiratory complications.
i. Encourage turning, coughing and deep breathing, and splinting the incision.
j. Ambulate as prescribed.
k. Prepare the client for discharge by providing instructions regarding pain management, wound care, and activity restrictions.
l. Instruct the client not to lift objects heavier than 15 to 20 lb for 6 to 12 weeks.
m. Advise the client to avoid activities requiring pushing, pulling, or straining.
n. Instruct the client not to drive a vehicle until approved by the PHCP.
o. Endovascular aneurysm grafting involves insertion of a graft using a vascular catheter; it does not require an abdominal incision. The preoperative and postoperative care is similar to that of a surgical abdominal aneurysm repair.

F. Thoracic aneurysm repair

1. Description

a. A thoracotomy or median sternotomy approach is used to enter the thoracic cavity.

b. The aneurysm is exposed and excised, and a graft or prosthesis is sewn onto the aorta.

c. Total cardiopulmonary bypass is necessary for excision of aneurysms in the ascending aorta.

d. Partial cardiopulmonary bypass is used for clients with an aneurysm in the descending aorta.

2. Postoperative interventions

a. Monitor vital signs and neurological and renal status.

b. Monitor for signs of hemorrhage, such as a drop in BP and increased pulse rate and respirations, and report them to the PHCP immediately.

c. Monitor chest tubes for an increase in chest drainage, which may indicate bleeding or separation at the graft site.
d. Assess sensation and motion of all extremities and notify the PHCP if deficits are noted, which can occur because of a lack of blood supply to the spinal cord during surgery.
e. Monitor respiratory status and auscultate breath sounds to identify respiratory complications.
f. Encourage turning, coughing, and deep breathing while splinting the incision.
g. Prepare the client for discharge by providing instructions regarding pain management, wound care, and activity restrictions.
h. Instruct the client not to lift objects heavier than 15 to 20 lb for 6 to 12 weeks.
i. Advise the client to avoid activities requiring pushing, pulling, or straining.
j. Instruct the client not to drive a vehicle until approved by the PHCP.

XIX. Embolectomy
A. Description
1. Embolectomy is removal of an embolus from an artery, using a catheter.
2. A patch graft may be required to close the artery.

B. Preoperative interventions
1. Obtain a baseline vascular assessment.
2. Administer anticoagulants as prescribed.
3. Administer thrombolytics as prescribed.
4. Place a bed cradle on the bed to keep the weight of linens from causing pain and pressure.
5. Avoid bumping or jarring the bed.
6. Maintain the extremity in a slightly dependent position.

C. Postoperative interventions
1. Assess cardiac, respiratory, and neurological status.
2. Monitor affected extremity for color, temperature, and pulse.
3. Assess sensory and motor function of the affected extremity.
5. Administer oxygen as prescribed.
7. Monitor for complications caused by reperfusion of
the artery, such as spasms and swelling of the skeletal muscles.
8. Monitor for signs of swollen skeletal muscles such as edema, pain on passive movement, poor capillary refill, numbness, and muscle tenseness.
9. Maintain bed rest initially, with the client in a semi-Fowler's position.
10. Place a bed cradle on the bed.
11. Check the incision site for bleeding or hematoma.
12. Administer anticoagulants as prescribed.
13. Monitor laboratory values related to anticoagulant therapy.
14. Instruct the client to recognize the signs and symptoms of infection and edema.
15. Instruct the client to avoid prolonged sitting or crossing the legs when sitting.
16. Instruct the client to elevate the legs when sitting.
17. Instruct the client to wear antiembolism stockings as prescribed and how to remove and reapply the stockings.
18. Instruct the client to ambulate daily.
19. Instruct the client about anticoagulant therapy and the hazards associated with anticoagulants.

XX. Vena Cava Filter
A. Vena cava filter: Insertion of an intracaval filter (umbrella) that partially occludes the inferior vena cava and traps emboli to prevent pulmonary emboli (Fig. 52-14)
B. The filter is placed through a catheter placed in a large vein in the neck or groin and advanced to the inferior vena cava.
C. Preoperative interventions: If the client has been taking an anticoagulant, consult with the PHCP regarding discontinuation of the medication preoperatively to prevent hemorrhage.
D. Postoperative interventions: similar to care after embolectomy.

XXI. Hypertension
A. Description
1. For an adult (ages 18 years and older), a normal BP is a systolic BP below 120 mm Hg and a diastolic pressure below 80 mm Hg.
2. Elevated blood pressure is defined as a systolic BP between 120 and 129 mm Hg and a diastolic BP below 80 mm Hg.
3. Hypertension (Stage 1) is defined as an SBP between 130 and 139 mm Hg or a diastolic BP between 80 and
89 mm Hg.
4. Hypertension (Stage 2) is defined as a SBP at least 140 mm Hg or a diastolic BP at least 90 mm Hg.
5. If either the SBP or DBP is outside of a range, the higher measurement will determine the classification.
6. Hypertension is a major risk factor for coronary, cerebral, renal, and peripheral vascular disease.
7. The disease is initially asymptomatic.
8. The goals of treatment include reduction of the BP and preventing or lessening the extent of organ damage.
9. Nonpharmacological approaches, such as lifestyle changes, may be prescribed initially; if the BP cannot be decreased after 1 to 3 months, the client may require pharmacological treatment.

B. Primary or essential hypertension

1. Risk factors
   a. Aging
   b. Family history
   c. African American race
   d. Obesity
   e. Smoking
   f. Stress
   g. Excessive alcohol
   h. Hyperlipidemia
   i. Increased intake of salt or caffeine

C. Secondary hypertension
   1. Secondary hypertension occurs as a result of other disorders or conditions.
   2. Treatment depends on the cause and the organs involved.
   3. Precipitating disorders or conditions
      a. Cardiovascular disorders
      b. Renal disorders
      c. Endocrine system disorders
      d. Pregnancy
      e. Medications (e.g., estrogens, glucocorticoids, mineralocorticoids)

D. Assessment
   1. May be asymptomatic
   2. Headache
   3. Visual disturbances
   4. Dizziness
   5. Chest pain
   6. Tinnitus
   7. Flushed face
8. Epistaxis

E. Interventions

1. Goals: To reduce the BP and to prevent or lessen the extent of organ damage
2. Question the client regarding the signs and symptoms of hypertension.
3. Obtain the BP 2 or more times on both arms, with the client supine and standing.
4. Compare the BP with prior documentation.
5. Determine family history of hypertension.
6. Identify current medication therapy.
7. Obtain weight.
8. Evaluate dietary patterns and sodium intake.
9. Assess for visual changes or retinal damage.
10. Assess for cardiovascular changes such as distended neck veins, increased heart rate, and dysrhythmias.
11. Evaluate chest x-ray for heart enlargement.
12. Assess the neurological system.
14. Evaluate results of diagnostic and laboratory studies.

F. Nonpharmacological interventions

1. Weight reduction, if necessary, or maintenance of ideal weight
2. Dietary sodium restriction to 2 g daily as prescribed
3. Moderate intake of alcohol and caffeine-containing products
4. Initiation of a regular exercise program
5. Avoidance of smoking
6. Relaxation techniques and biofeedback therapy
7. Elimination of unnecessary medications that may contribute to the hypertension

G. Pharmacological interventions

1. Medication therapy is individualized for each client, and the selection of the medication is based on such factors as the client’s age, presence of coexisting conditions, severity of the hypertension, and client’s preferences.
2. See Chapter 53 for medications to treat hypertension.

H. See Box 52-10 for client education.

XXII. Hypertensive Crisis

A. Description

1. A hypertensive crisis is an acute and life-threatening condition requiring immediate reduction in BP.
2. Emergency treatment is required, because target organ damage (brain, heart, kidneys, retina of the eye) can occur quickly.
3. Death can be caused by stroke, kidney failure, or cardiac disease.
B. Assessment
1. An extremely high BP; systolic over 180 mm Hg and/or diastolic over 120 mm Hg
2. Headache
3. Drowsiness and confusion
4. Blurred vision
5. Changes in neurological status
6. Tachycardia and tachypnea
7. Dyspnea
8. Cyanosis
9. Seizures

C. Interventions
1. Maintain a patent airway.
2. Administer antihypertensive medications intravenously as prescribed.
3. Monitor vital signs, assessing the BP every 5 minutes.
5. Maintain bed rest, with the head of the bed elevated at 45 degrees.
6. Assess for hypotension during the administration of antihypertensives; place the client in a supine position if hypotension occurs.
7. Have emergency medications and resuscitation equipment readily available.
8. Monitor IV therapy, assessing for fluid overload.
9. Insert a Foley catheter as prescribed.
10. Monitor intake and urinary output; if oliguria or anuria occurs, notify the PHCP.
FIG. 52-1 Coronary arterial system.

Box 52-1
Basics of Electrocardiography

- An electrocardiogram (ECG) reflects the electrical activity of cardiac cells and records electrical activity at a speed of 25 mm/second.
- An electrocardiographic strip consists of horizontal lines representing seconds and vertical lines representing voltage.
- Each small square represents 0.04 second.
- Each large square represents 0.20 second.
- The P wave represents atrial depolarization.
- The PR interval represents the time it takes an impulse to travel from the atria through the atrioventricular node, bundle of His, and bundle branches to the Purkinje fibers.
- Normal PR interval duration ranges from 0.12 to 0.2 second.
- The PR interval is measured from the beginning of the P wave to the end of the PR segment.
- The QRS complex represents ventricular depolarization.
• Normal QRS complex duration ranges from 0.04 to 0.1 second.
• The Q wave appears as the first negative deflection in the QRS complex and reflects initial ventricular septal depolarization.
• The R wave is the first positive deflection in the QRS complex.
• The S wave appears as the second negative deflection in the QRS complex.
• The J point marks the end of the QRS complex and the beginning of the ST segment.
• The QRS duration is measured from the end of the PR segment to the J point.
• The ST segment represents early ventricular repolarization.
• The T wave represents ventricular repolarization and ventricular diastole.
• The U wave may follow the T wave.
• A prominent U wave may indicate an electrolyte abnormality, such as hypokalemia.
• The QT interval represents ventricular refractory time or the total time required for ventricular depolarization and repolarization.
• The QT interval is measured from the beginning of the QRS complex to the end of the T wave.
• The QT interval normally lasts 0.32 to 0.4 second but varies with the client’s heart rate, age, and gender.
FIG. 52-2  Right-sided heart catheterization. The catheter is inserted into the femoral vein and advanced into the inferior vena cava (or, if into an antecubital or basilic vein, through the superior vena cava), right atrium, right ventricle, and pulmonary artery.
Box 52-2

Home Care Instructions for the Client After Cardiac Surgery

- Progressive return to activities at home
- Limiting of pushing or pulling activities for 6 weeks following discharge
- Maintenance of incisional care and recording signs of redness, swelling, or drainage
- Sternotomy incision heals in about 6 to 8 weeks
- Avoidance of crossing legs; wearing elastic hose as prescribed until edema subsides, and elevating the surgical limb (if used to obtain the graft) when
sitting in a chair

- Use of prescribed medications
- Dietary measures, including the avoidance of saturated fats and cholesterol and the use of salt
- Resumption of sexual intercourse on the advice of the primary health care provider or cardiologist after exercise tolerance is assessed (usually, if the client can walk 1 block or climb 2 flights of stairs without symptoms, she or he can resume sexual activity safely)

**FIG. 52-5** Normal sinus rhythm. Both atrial and ventricular rhythms are essentially regular (a slight variation in rhythm is normal). Atrial and ventricular rates are both 83 beats per minute. There is one P wave before each QRS complex, and all P waves are of a consistent morphology, or shape. The PR interval measures 0.18 seconds and is constant; the QRS complex measures 0.06 seconds and is constant.

**FIG. 52-6** Each segment between the dark lines (above the monitor strip) represents 3 seconds when the monitor is set at a speed of 25 mm/second. To estimate the ventricular rate, count the QRS complexes in a 6-second strip and then multiply that number by 10 to estimate the heart rate for 1 minute. In this example, there are 9 QRS complexes in 6 seconds. Therefore, the heart rate can be estimated as 90 beats per minute.

**Box 52-3**

**Determination of Heart Rate Using 6-Second Strip Method**

- The method can be used to determine heart rate for regular and irregular rhythms.
- To determine atrial rate, count the number of P waves in 6 seconds and multiply by 10 to obtain a full minute rate.
- To determine ventricular rate, count the number of R waves or QRS complexes in 6 seconds and multiply by 10 to obtain a full minute rate.
• For accuracy, timing should begin on the P wave or the QRS complex and end exactly at 30 large blocks later.

**FIG. 52-7** Atrial dysrhythmias—atrial fibrillation.

**FIG. 52-8** Ventricular dysrhythmias—normal sinus rhythm with multifocal premature ventricular contractions (PVCs; one negative and the other positive).

**Box 52-4**

**Premature Ventricular Contractions**

*Bigeminy:* Premature ventricular contraction (PVC) every other heartbeat  
*Trigeminy:* PVC every third heartbeat  
*Quadrigeminy:* PVC every fourth heartbeat  
*Couplet or pair:* Two sequential PVCs  
*Unifocal:* Uniform upward or downward deflection, arising from the same ectopic focus  
*Multifocal:* Different shapes, with the impulse generation from different sites  
*R-on-T phenomenon:* PVC falls on the T wave of the preceding beat; may precipitate ventricular fibrillation
Box 52-5

Pacemakers: Client Education

- Instruct the client about the pacemaker, including the programmed rate.
- Instruct the client in the signs of battery failure and when to notify the primary health care provider (PHCP) or cardiologist.
- Instruct the client to report any fever, redness, swelling, or drainage from the insertion site.
- Report signs of dizziness, weakness or fatigue, swelling of the ankles or legs, chest pain, or shortness of breath.
- Keep a pacemaker identification card in the wallet and obtain and wear a MedicAlert bracelet.
- Instruct the client in how to take the pulse, to take the pulse daily, and to maintain a diary of pulse rates.
- Wear loose-fitting clothing over the pulse generator site.
- Avoid contact sports.
- Inform all PHCPs that a pacemaker has been inserted.
- Instruct the client to inform airport security that she or he has a pacemaker, because the pacemaker may set off the security detector.
- Instruct the client that most electrical appliances can be used without any interference with the functioning of the pacemaker; however, advise the client not to operate electrical appliances directly over the pacemaker site.
- Avoid transmitter towers and antitheft devices in stores.
• Instruct the client that if any unusual feelings occur when near any electrical devices, to move 5 to 10 feet away and check the pulse.
• Instruct the client about the methods of monitoring the function of the device.
• Emphasize the importance of follow-up with the PHCP.
• Use cellphones on the side opposite the pacemaker.
Chronic Causes of Endothelial Injury:
- Hemodynamic factors
- Hyperhomocysteinemia
- Hyperlipidemia
- Hypertension
- Immune reactions
- Smoking
- Toxins
- Viruses

Response to injury
- Endothelium
- Tunica intima
- Tunica media
- Adventitia
- Platelets
- Lipids
- Damaged endothelium

Fatty streak
- Foamy macrophage ingesting lipids
- Platelets attach to endothelium
- Lipid accumulation
- Migration of smooth muscle into the intima
- Fibroblast

Fibrous plaque
- Collagen cap (fibrous tissue)
- Fibroblast
- Fissure in plaque
- Lipid pool

Complicated lesion
- Thrombus
- Thinning collagen cap
- Lipid pool
Complications of Myocardial Infarction

- Dysrhythmias
- Heart failure
- Pulmonary edema
- Cardiogenic shock
- Thrombophlebitis
- Pericarditis
- Mitral valve insufficiency
- Postinfarction angina
- Ventricular rupture
- Dressler’s syndrome (a combination of pericarditis, pericardial effusion, and pleural effusion, which can occur several weeks to months following a myocardial infarction)

Home Care Instructions for the Client with Infective Endocarditis

- Teach the client to maintain aseptic technique during setup and administration
of intravenous (IV) antibiotics.

- Instruct the client to administer IV antibiotics at scheduled times to maintain the blood level.
- Instruct the client to monitor IV catheter sites for signs of infection and report this immediately to the primary health care provider (PHCP) or cardiologist.
- Instruct the client to record the temperature daily for up to 6 weeks and to report fever.
- Encourage oral hygiene at least twice a day with a soft toothbrush and rinse well with water after brushing.
- Client should avoid use of oral irrigation devices and flossing to avoid bacteremia.
- Teach the client to cleanse any skin lacerations thoroughly and apply an antibiotic ointment as prescribed.
- Client should inform all PHCPs of history of endocarditis and ask about the use of prophylactic antibiotics prior to invasive respiratory procedures and dentistry.
- Teach the client to observe for signs and symptoms of embolic conditions and heart failure.

### Table 52-3

**Tricuspid Valve Disorders**
Adequate rest is important, and fatigue is common.

- Anticoagulant therapy is necessary if a mechanical prosthetic valve has been inserted.
- Instruct the client concerning hazards related to anticoagulant therapy and to notify the primary health care provider (PHCP) or cardiologist if bleeding or excessive bruising occurs.
- Instruct the client concerning the importance of good oral hygiene to reduce the risk of infective endocarditis.
- Brush teeth twice daily with a soft toothbrush, followed by oral rinses.
- Avoid irrigation devices, electric toothbrushes, and flossing, because these...
activities can cause the gums to bleed, allowing bacteria to enter the mucous membranes and bloodstream.

- Monitor incision and report any drainage or redness.
- Avoid any dental procedures for 6 months.
- Heavy lifting (more than 10 lb [4.5 kg]) is to be avoided, and exercise caution when in an automobile to prevent injury to the sternal incision.
- If a prosthetic valve was inserted, a soft, audible, clicking sound may be heard.
- Instruct the client concerning the importance of prophylactic antibiotics before any invasive procedure and the importance of informing all PHCPs of history of valve replacement or repair.
- Obtain and wear a MedicAlert bracelet.

|                       | • Digesin, nitrates, and other vasodilators contraindicated with the obstructed form |                        |                           |

Instructions for the Client with Deep Vein Thrombophlebitis

- Instruct the client concerning the hazards of anticoagulation therapy.
- Recognize the signs and symptoms of bleeding.
- Avoid prolonged sitting or standing, constrictive clothing, or crossing the legs when seated.
- Elevate the legs for 10 to 20 minutes every few hours each day.
- Plan a progressive walking program.
- Inspect the legs for edema, and measure the circumference of the legs.
- Wear antiembolism stockings as prescribed.
- Avoid smoking.
- Avoid any medications unless prescribed by the primary health care provider (PHCP) or cardiologist.
- Instruct the client concerning the importance of follow-up PHCP visits and laboratory studies.
- Obtain and wear a MedicAlert bracelet.
FIG. 52-12 In aortoiliac and aortofemoral bypass surgery, a midline incision into the abdominal cavity is required, with an additional incision in each groin.
FIG. 52-13  Surgical repair of an abdominal aortic aneurysm with a woven Dacron graft.
Box 52-10

Education for the Client with Hypertension

- Describe the importance of adherence with the treatment plan.
- Describe the disease process, explaining that symptoms usually do not develop until organs have suffered damage.
- Initiate and assist the client in planning a regular exercise program, avoiding heavy weight-lifting and isometric exercises.
- Emphasize the importance of beginning the exercise program gradually.
- Encourage the client to express feelings about daily stress.
▪ Assist the client to identify ways to reduce stress.
▪ Teach relaxation techniques.
▪ Instruct the client in how to incorporate relaxation techniques into the daily living pattern.
▪ Instruct the client and family in the technique for monitoring blood pressure (BP).
▪ Instruct the client to maintain a diary of BP readings.
▪ Emphasize the importance of lifelong medication.
▪ Instruct the client and family about dietary restrictions, which may include sodium, fat, calories, and cholesterol.
▪ Instruct the client in how to shop for and prepare low-sodium meals.
▪ Provide a list of products that contain sodium.
▪ Instruct the client to read labels of products to determine sodium content, focusing on substances listed as sodium, NaCl, or MSG (monosodium glutamate).
▪ Instruct the client to bake, roast, or boil foods; avoid salt in preparation of foods; and avoid using salt at the table.
▪ Instruct the client that fresh foods are best to consume, and to avoid canned foods.
▪ Instruct the client about the actions, side effects, and scheduling of medications.
▪ Advise the client that if uncomfortable side effects occur, to contact the primary health care provider or cardiologist and not to stop the medication.
▪ Instruct the client to avoid over-the-counter medications.
▪ Stress the importance of follow-up care.

Flash Priority Nursing Actions

Pulmonary Edema

1. Place the client in a high-Fowler’s position.
2. Administer oxygen.
3. Assess the client quickly, including assessing lung sounds.
4. Ensure that an intravenous (IV) access device is in place.
5. Prepare for the administration of a diuretic and morphine sulfate.
6. Insert a Foley catheter as prescribed.
7. Prepare for intubation and ventilator support, if required.
8. Document the event, actions taken, and the client’s response.

Practice Questions

600. A client is admitted to the emergency department with chest pain that is consistent with myocardial infarction based on elevated troponin levels.
Heart sounds are normal. The nurse should alert the primary health care provider because the vital sign changes and client assessment are most consistent with which complication? **Refer to chart.**

1. Cardiogenic shock  
2. Cardiac tamponade  
3. Pulmonary embolism  
4. Dissecting thoracic aortic aneurysm

601. A client with a history of type 2 diabetes is admitted to the hospital with chest pain. The client is scheduled for a cardiac catheterization. Which medication would need to be withheld for 24 hours before the procedure and for 48 hours after the procedure?
   1. Glipizide  
   2. Metformin  
   3. Repaglinide  
   4. Regular insulin

602. A client in sinus bradycardia, with a heart rate of 45 beats per minute and blood pressure of 82/60 mm Hg, reports dizziness. Which intervention should the nurse anticipate will be prescribed?
   1. Administer digoxin.  
   2. Defibrillate the client.  
   3. Continue to monitor the client.  
   4. Prepare for transcutaneous pacing.

603. The nurse in a medical unit is caring for a client with heart failure. The client suddenly develops extreme dyspnea, tachycardia, and lung crackles. The nurse immediately asks another nurse to contact the primary health care provider and prepares to implement which **priority** interventions? **Select all that apply.**
   1. Administering oxygen  
   2. Inserting a Foley catheter  
   3. Administering furosemide  
   4. Administering morphine sulfate intravenously  
   5. Transporting the client to the coronary care unit  
   6. Placing the client in a low-Fowler’s side-lying position

604. A client with myocardial infarction suddenly becomes tachycardic, shows signs of air hunger, and begins coughing frothy, pink-tinged sputum. Which finding would the nurse anticipate when auscultating the client’s breath sounds?
   1. Stridor
2. Crackles
3. Scattered rhonchi
4. Diminished breath sounds

605. A client with myocardial infarction is developing cardiogenic shock. What condition should the nurse carefully assess the client for?
   1. Pulsus paradoxus
   2. Ventricular dysrhythmias
   3. Rising diastolic blood pressure
   4. Falling central venous pressure

606. A client who had cardiac surgery 24 hours ago has had a urine output averaging 20 mL/hr for 2 hours. The client received a single bolus of 500 mL of intravenous fluid. Urine output for the subsequent hour was 25 mL. Daily laboratory results indicate that the blood urea nitrogen level is 45 mg/dL (16 mmol/L) and the serum creatinine level is 2.2 mg/dL (194 mcmol/L). On the basis of these findings, the nurse would anticipate that the client is at risk for which problem?
   1. Hypovolemia
   2. Acute kidney injury
   3. Glomerulonephritis
   4. Urinary tract infection

607. The nurse is reviewing an electrocardiogram rhythm strip. The P waves and QRS complexes are regular. The PR interval is 0.16 seconds, and QRS complexes measure 0.06 seconds. The overall heart rate is 64 beats per minute. Which action should the nurse take?
   1. Check vital signs.
   2. Check laboratory test results.
   3. Monitor for any rhythm change.
   4. Notify the primary health care provider.

608. A client is wearing a continuous cardiac monitor, which begins to sound its alarm. The nurse sees no electrocardiographic complexes on the screen. Which is the priority nursing action?
   1. Call a code.
   2. Check the client’s status.
   3. Call the health care provider.

609. The nurse is watching the cardiac monitor and notices that a client’s rhythm suddenly changes. There are no P waves, the QRS complexes are wide, and the ventricular rate is regular but more than 140 beats per minute. The nurse determines that the client is experiencing which dysrhythmia?
   1. Sinus tachycardia
   2. Ventricular fibrillation
   3. Ventricular tachycardia
   4. Premature ventricular contractions

610. A client has frequent bursts of ventricular tachycardia on the cardiac monitor. What should the nurse be most concerned about with this dysrhythmia?
   1. It can develop into ventricular fibrillation at any time.
   2. It is almost impossible to convert to a normal rhythm.
3. It is uncomfortable for the client, giving a sense of impending doom.
4. It produces a high cardiac output with cerebral and myocardial ischemia.

611. A client is having frequent premature ventricular contractions. The nurse should place **priority** on assessment of which item?
1. Causative factors, such as caffeine
2. Sensation of fluttering or palpitations
3. Blood pressure and oxygen saturation
4. Precipitating factors, such as infection

612. The client has developed atrial fibrillation, with a ventricular rate of 150 beats per minute. The nurse should assess the client for which associated signs and/or symptoms? **Select all that apply.**

- [ ] 1. Syncope
- [ ] 2. Dizziness
- [ ] 3. Palpitations
- [ ] 4. Hypertension
- [ ] 5. Flat neck veins

613. The nurse is watching the cardiac monitor, and a client’s rhythm suddenly changes. There are no P waves; instead, there are fibrillatory waves before each QRS complex. How should the nurse interpret the client’s heart rhythm?
1. Atrial fibrillation
2. Sinus tachycardia
3. Ventricular fibrillation
4. Ventricular tachycardia

614. The nurse is assisting to defibrillate a client in ventricular fibrillation. After placing the pads on the client’s chest and before discharging the device, which intervention is a **priority**?
1. Ensure that the client has been intubated.
2. Set the defibrillator to the “synchronize” mode.
3. Administer an amiodarone bolus intravenously.
4. Confirm that the rhythm is ventricular fibrillation.

615. A client in ventricular fibrillation is about to be defibrillated. To convert this rhythm effectively, the monophasic defibrillator machine should be set at which energy level (in joules, J) for the first delivery?
1. 50 J
2. 120 J
3. 200 J
4. 360 J

616. The nurse should evaluate that defibrillation of a client was **most** successful if which observation was made?
1. Arousable, sinus rhythm, blood pressure (BP) 116/72 mm Hg
2. Nonarousable, sinus rhythm, BP 88/60 mm Hg
3. Arousable, marked bradycardia, BP 86/54 mm Hg
4. Nonarousable, supraventricular tachycardia, BP 122/60 mm Hg

617. The nurse is evaluating a client’s response to cardioversion. Which assessment would be the priority?
1. Blood pressure
2. Airway patency
3. Oxygen flow rate
4. Level of consciousness

618. The nurse is caring for a client who has just had implantation of an automatic internal cardioverter-defibrillator. The nurse should assess which item based on priority?
1. Anxiety level of the client and family
2. Activation status and settings of the device
3. Presence of a MedicAlert card for the client to carry
4. Knowledge of restrictions on postdischarge physical activity

619. A client’s electrocardiogram strip shows atrial and ventricular rates of 110 beats per minute. The PR interval is 0.14 seconds, the QRS complex measures 0.08 seconds, and the PP and RR intervals are regular. How should the nurse interpret this rhythm?
1. Sinus tachycardia
2. Sinus bradycardia
3. Sinus dysrhythmia
4. Normal sinus rhythm

620. The nurse is assessing the neurovascular status of a client who returned to the surgical nursing unit 4 hours ago after undergoing aortoiliac bypass graft. The affected leg is warm, and the nurse notes redness and edema. The pedal pulse is palpable. How should the nurse interpret the client’s neurovascular status?
1. The neurovascular status is normal because of increased blood flow through the leg.
2. The neurovascular status is moderately impaired, and the surgeon should be called.
3. The neurovascular status is slightly deteriorating and should be monitored for another hour.
4. The neurovascular status shows adequate arterial flow, but venous complications are arising.

621. The nurse is evaluating the condition of a client after pericardiocentesis performed to treat cardiac tamponade. Which observation would indicate that the procedure was effective?
1. Muffled heart sounds
2. Client reports dyspnea
3. A rise in blood pressure
4. Jugular venous distention

622. The nurse is caring for a client who had a resection of an abdominal aortic aneurysm yesterday. The client has an intravenous (IV) infusion at a rate of 150 mL/hr, unchanged for the last 10 hours. The client’s urine output for the last 3 hours has been 90, 50, and 28 mL (28 mL is most recent). The client’s blood urea nitrogen level is 35 mg/dL (12.6 mmol/L), and the serum creatinine level is 1.8 mg/dL (159 mcmol/L), measured this morning. Which
nursing action is the priority?
1. Check the serum albumin level.
2. Check the urine specific gravity.
3. Continue monitoring urine output.
4. Call the primary health care provider (PHCP).

623. A client with variant angina is scheduled to receive an oral calcium channel blocker twice daily. Which statement by the client indicates the need for further teaching?

1. “I should notify my cardiologist if my feet or legs start to swell.”
2. “I am supposed to report to my cardiologist if my pulse rate decreases below 60.”
3. “Avoiding grapefruit juice will definitely be a challenge for me, since I usually drink it every morning with breakfast.”
4. “My spouse told me that since I have developed this problem, we are going to stop walking in the mall every morning.”

624. The nurse notes that a client with sinus rhythm has a premature ventricular contraction that falls on the T wave of the preceding beat. The client’s rhythm suddenly changes to one with no P waves, no definable QRS complexes, and coarse wavy lines of varying amplitude. How should the nurse interpret this rhythm?

1. Asystole
2. Atrial fibrillation
3. Ventricular fibrillation
4. Ventricular tachycardia

Answers

600. Answer: 1

Rationale: Cardiogenic shock occurs with severe damage (more than 40%) to the left ventricle. Classic signs include hypotension; a rapid pulse that becomes weaker; decreased urine output; and cool, clammy skin. Respiratory rate increases as the body develops metabolic acidosis from shock. Cardiac tamponade is accompanied by distant, muffled heart sounds and prominent neck vessels. Pulmonary embolism presents suddenly with severe dyspnea accompanying the chest pain. Dissecting aortic aneurysms usually are accompanied by back pain.

Test-Taking Strategy: Note the strategic word, most. Recalling that the early serious complications of myocardial infarction include dysrhythmias, cardiogenic shock, and sudden death will direct you to the correct option. No information in the question is associated with the remaining options.

Level of Cognitive Ability: Synthesizing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Analysis
Content Area: Complex Care: Shock
Health Problem: Adult Health: Cardiovascular: Shock
Priority Concepts: Clinical Judgment; Perfusion
601. Answer: 2

**Rationale:** Metformin needs to be withheld 24 hours before and for 48 hours after cardiac catheterization because of the injection of contrast medium during the procedure. If the contrast medium affects kidney function, with metformin in the system the client would be at increased risk for lactic acidosis. The medications in the remaining options do not need to be withheld before and after cardiac catheterization.

**Test-Taking Strategy:** Eliminate glipizide and repaglinide first because they are **comparable or alike.** Although these medications may be withheld on the morning of the procedure because of the client’s NPO (nothing by mouth) status, there is no indication for withholding the medication on the day prior to the procedure and postprocedure. Regular insulin may be administered if elevated blood glucose levels from infused intravenous solutions occur on the day of the procedure.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Planning

**Content Area:** Pharmacology: Endocrine: Oral hypoglycemic

**Health Problem:** Adult Health: Cardiovascular: Coronary Artery Disease

**Priority Concepts:** Perfusion; Safety

602. Answer: 4

**Rationale:** Sinus bradycardia is noted with a heart rate less than 60 beats per minute. This rhythm becomes a concern when the client becomes symptomatic. Hypotension and dizziness are signs of decreased cardiac output. Transcutaneous pacing provides a temporary measure to increase the heart rate and thus perfusion in the symptomatic client. Defibrillation is used for treatment of pulseless ventricular tachycardia and ventricular fibrillation. Digoxin will further decrease the client’s heart rate. Continuing to monitor the client delays necessary intervention.

**Test-Taking Strategy:** Focus on the subject, interventions for sinus bradycardia. Eliminate the option indicating to continue to monitor the client, because the client is symptomatic and requires intervention. Digoxin is eliminated because it will further decrease the client’s heart rate. Defibrillation is used for treatment of pulseless ventricular tachycardia and ventricular fibrillation, so that option can be eliminated.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Planning

**Content Area:** Complex Care: Emergency Situations/Management

**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias

**Priority Concepts:** Gas Exchange; Perfusion

603. Answer: 1, 2, 3, 4

**Rationale:** Extreme dyspnea, tachycardia, and lung crackles in a client with heart
failure indicate pulmonary edema, a life-threatening event. In pulmonary edema, the left ventricle fails to eject sufficient blood, and pressure increases in the lungs because of the accumulated blood. Oxygen is always prescribed, and the client is placed in a high-Fowler’s position to ease the work of breathing. Furosemide, a rapid-acting diuretic, will eliminate accumulated fluid. A Foley catheter is inserted to measure output accurately. Intravenously administered morphine sulfate reduces venous return (preload), decreases anxiety, and also reduces the work of breathing. Transporting the client to the coronary care unit is not a priority intervention. In fact, this may not be necessary at all if the client’s response to treatment is successful. 

Test-Taking Strategy: Note the strategic word, priority, and focus on the client’s diagnosis. Recall the pathophysiology associated with pulmonary edema and use the ABCs—airway, breathing, and circulation—to help determine priority interventions.

Level of Cognitive Ability: Synthesizing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Complex Care: Emergency Situations/Management
Health Problem: Adult Health: Cardiovascular: Heart Failure
Priority Concepts: Gas Exchange; Perfusion

604. Answer: 2

Rationale: Pulmonary edema is characterized by extreme breathlessness, dyspnea, air hunger, and the production of frothy, pink-tinged sputum. Auscultation of the lungs reveals crackles. Rhonchi and diminished breath sounds are not associated with pulmonary edema. Stridor is a crowing sound associated with laryngospasm or edema of the upper airway.

Test-Taking Strategy: Focus on the subject, breath sounds characteristic of pulmonary edema. Recalling that fluid produces sounds that are called cracks will assist you in eliminating the incorrect options.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Complex Care: Emergency Situations/Management
Health Problem: Adult Health: Cardiovascular: Myocardial Infarction
Priority Concepts: Gas Exchange; Perfusion

605. Answer: 2

Rationale: Dysrhythmias commonly occur as a result of decreased oxygenation and severe damage to greater than 40% of the myocardium. Classic signs of cardiogenic shock as they relate to myocardial ischemia include low blood pressure and tachycardia. The central venous pressure would rise as the backward effects of the severe left ventricular failure became apparent. Pulsus paradoxus is a finding associated with cardiac tamponade.
**Test-Taking Strategy:** Focus on the subject, cardiogenic shock, and note the words *myocardial ischemia*. Recall that ischemia makes the myocardium irritable, producing dysrhythmias. Also, knowledge of the classic signs of shock helps eliminate the incorrect options.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Complex Care: Emergency Situations/Management

**Health Problem:** Adult Health: Cardiovascular: Shock

**Priority Concepts:** Clinical Judgment; Perfusion

606. **Answer:** 2

**Rationale:** The client who undergoes cardiac surgery is at risk for renal injury from poor perfusion, hemolysis, low cardiac output, or vasopressor medication therapy. Renal injury is signaled by decreased urine output and increased blood urea nitrogen (BUN) and creatinine levels. Normal reference levels are BUN, 10 to 20 mg/dL (3.6 to 7.1 mmol/L), and creatinine 0.6 to 1.2 mg/dL (53 to 106 mcmol/L) for males and 0.5 to 1.1 mg/dL (44 to 97 mcmol/L) for females. The client may need medications to increase renal perfusion and possibly could need peritoneal dialysis or hemodialysis. No data in the question indicate the presence of hypovolemia, glomerulonephritis, or urinary tract infection.

**Test-Taking Strategy:** Eliminate glomerulonephritis and urinary tract infection first because they are comparable or alike in that there are no data indicating infection or inflammation. Noting that the creatinine level is elevated and the minimal urinary response to the fluid bolus will assist you in eliminating hypovolemia.

**Level of Cognitive Ability:** Synthesizing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Analysis

**Content Area:** Adult Health: Renal and Urinary

**Health Problem:** Adult Health: Cardiovascular: Coronary Artery Disease

**Priority Concepts:** Clinical Judgment; Perfusion

607. **Answer:** 3

**Rationale:** Normal sinus rhythm is defined as a regular rhythm, with an overall rate of 60 to 100 beats per minute. The PR and QRS measurements are normal, measuring between 0.12 and 0.20 seconds and 0.04 and 0.10 seconds, respectively. There are no irregularities in this rhythm currently, so there is no immediate need to check vital signs or laboratory results, or to notify the primary health care provider. Therefore, the nurse would continue to monitor the client for any rhythm change.

**Test-Taking Strategy:** Focus on the subject, electrocardiogram rhythm strip measurements. A baseline knowledge of normal electrocardiographic measurements is needed to answer this question. Focusing on the data in the question and recalling
the characteristics of normal sinus rhythm will help you prioritize your actions.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process: Implementation  
**Content Area:** Adult Health: Cardiovascular  
**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias  
**Priority Concepts:** Clinical Judgment; Perfusion  

608. **Answer:** 2

**Rationale:** Sudden loss of electrocardiographic complexes indicates ventricular asystole or possibly electrode displacement. Accurate assessment of the client is necessary to determine the cause and identify the appropriate intervention. The remaining options are secondary to client assessment.

**Test-Taking Strategy:** Note the **strategic word,** *priority.* Use the **steps of the nursing process.** Always assess the client directly before taking any action related to equipment. The correct option is the only one that addresses assessment.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Complex Care: Emergency Situations/Management  
**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias  
**Priority Concepts:** Clinical Judgment; Perfusion  
**Reference:** Lewis et al. (2014), p. 790.

609. **Answer:** 3

**Rationale:** Ventricular tachycardia is characterized by the absence of P waves, wide QRS complexes (longer than 0.12 seconds), and typically a rate between 140 and 180 impulses per minute. The rhythm is regular.

**Test-Taking Strategy:** Focus on the **subject,** the characteristics of an electrocardiogram pattern, and note the **data in the question.** Eliminate sinus tachycardia first, because there are no P waves. Premature ventricular contractions are isolated ectopic beats superimposed on an underlying rhythm, so that option is eliminated next. Recalling that there are no true QRS complexes with ventricular fibrillation will direct you to the correct option from those remaining.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Complex Care: Emergency Situations/Management  
**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias  
**Priority Concepts:** Clinical Judgment; Perfusion  
**Reference:** Lewis et al. (2014), pp. 794, 799-800.

610. **Answer:** 1
**Rationale:** Ventricular tachycardia is a life-threatening dysrhythmia that results from an irritable ectopic focus that takes over as the pacemaker for the heart. Ventricular tachycardia can deteriorate into ventricular fibrillation at any time. Clients frequently experience a feeling of impending doom. The low cardiac output that results can lead quickly to cerebral and myocardial ischemia. Ventricular tachycardia is treated with antidysrhythmic medications, cardioversion (if the client is awake), or defibrillation (loss of consciousness).

**Test-Taking Strategy:** Note the strategic word, *most*. The option indicating that it is impossible to convert is incorrect and is eliminated first. From the remaining options, focusing on the strategic word will direct you to the correct option because this option identifies the life-threatening condition.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Analysis

**Content Area:** Complex Care: Emergency Situations/Management

**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias

**Priority Concepts:** Clinical Judgment; Perfusion

611. **Answer:** 3

**Rationale:** Premature ventricular contractions can cause hemodynamic compromise. Therefore, the priority is to monitor the blood pressure and oxygen saturation. The shortened ventricular filling time can lead to decreased cardiac output. The client may be asymptomatic or may feel palpitations. Premature ventricular contractions can be caused by cardiac disorders; states of hypoxemia; any number of physiological stressors, such as infection, illness, surgery, or trauma; and intake of caffeine, nicotine, or alcohol.

**Test-Taking Strategy:** Note the strategic word, *priority*. Use the ABCs—airway, breathing, and circulation—to direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Complex Care: Emergency Situations/Management

**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias

**Priority Concepts:** Clinical Judgment; Perfusion

**Reference:** Lewis et al. (2014), p. 799.

612. **Answer:** 1, 2, 3

**Rationale:** The client with uncontrolled atrial fibrillation with a ventricular rate more than 100 beats per minute is at risk for low cardiac output because of loss of atrial kick. The nurse assesses the client for palpitations, chest pain or discomfort, hypotension, pulse deficit, fatigue, weakness, dizziness, syncope, shortness of breath, and distended neck veins. Hypertension and flat neck veins are not associated with the loss of cardiac output.

**Test-Taking Strategy:** Focus on the subject, signs and/or symptoms associated
with atrial fibrillation. Flat neck veins are normal or indicate hypovolemia, so this option can be eliminated. From the remaining options, think of the consequences of a falling cardiac output to direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Complex Care: Emergency Situations/Management  
**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias  
**Priority Concepts:** Clinical Judgment; Perfusion  
**Reference:** Lewis et al. (2014), p. 707.

613. **Answer:** 1

**Rationale:** Atrial fibrillation is characterized by a loss of P waves and fibrillatory waves before each QRS complex. The atria quiver, which can lead to thrombus formation.

**Test-Taking Strategy:** Focus on the **subject**, interpreting a heart rhythm. Note the data in the question. Noting the words *There are no P waves* should direct you to the correct option. Loss of P waves is characteristic of this dysrhythmia.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Complex Care: Emergency Situations/Management  
**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias  
**Priority Concepts:** Clinical Judgment; Perfusion  

614. **Answer:** 4

**Rationale:** Until the defibrillator is attached and charged, the client is resuscitated by using cardiopulmonary resuscitation. Once the defibrillator has been attached, the electrocardiogram is checked to verify that the rhythm is ventricular fibrillation or pulseless ventricular tachycardia. Leads also are checked for any loose connections. A nitroglycerin patch, if present, is removed. The client does not have to be intubated to be defibrillated. The machine is not set to the synchronous mode because there is no underlying rhythm with which to synchronize.

**Test-Taking Strategy:** Note the **strategic word**, priority. Focus on the **subject**, ventricular fibrillation. Note that the correct option directly addresses this subject and also addresses assessment of the client.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Complex Care: Basic Life Support/Cardiopulmonary Resuscitation/Cardiac Arrest  
**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias  
**Priority Concepts:** Perfusion; Safety  
**Reference:** Lewis et al. (2014), pp. 801-802.
615. **Answer:** 4

**Rationale:** The energy level used for all defibrillation attempts with a monophasic defibrillator is 360 joules.

**Test-Taking Strategy:** Focus on the subject, monophasic defibrillation. As a general rule, though, remember that lower levels of energy are used for cardioversion and biphasic defibrillation. Higher levels are used in monophasic defibrillation.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Complex Care: Basic Life Support/Cardiopulmonary  
**Resuscitation/Cardiac Arrest**  
**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias  
**Priority Concepts:** Perfusion; Safety  
**Reference:** Lewis et al. (2014), p. 802.

616. **Answer:** 1

**Rationale:** After defibrillation, the client requires continuous monitoring of electrocardiographic rhythm, hemodynamic status, and neurological status. Respiratory and metabolic acidosis develop during ventricular fibrillation because of lack of respiration and cardiac output. These can cause cerebral and cardiopulmonary complications. Arousalable status, adequate BP, and a sinus rhythm indicate successful response to defibrillation.

**Test-Taking Strategy:** Note the strategic word, most. Eliminate the options that contain the word nonarousable. From the remaining options, select the correct option, because a sinus rhythm is a more successful response compared with marked bradycardia.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Complex Care: Basic Life Support/Cardiopulmonary  
**Resuscitation/Cardiac Arrest**  
**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias  
**Priority Concepts:** Evidence; Perfusion  

617. **Answer:** 2

**Rationale:** Nursing responsibilities after cardioversion include maintenance first of a patent airway, and then oxygen administration, assessment of vital signs and level of consciousness, and dysrhythmia detection.

**Test-Taking Strategy:** Note the strategic word, priority. Use the ABCs—airway, breathing, and circulation—to direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity
618. **Answer:** 2

**Rationale:** The nurse who is caring for the client after insertion of an automatic internal cardioverter-defibrillator needs to assess device settings, similar to after insertion of a permanent pacemaker. Specifically, the nurse needs to know whether the device is activated, the heart rate cutoff above which it will fire, and the number of shocks it is programmed to deliver. The remaining options are also nursing interventions but are not the priority.

**Test-Taking Strategy:** Note the strategic word, priority. Use Maslow’s Hierarchy of Needs theory. The correct option is the one that identifies the physiological need.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Cardiovascular

**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias

**Priority Concepts:** Clinical Judgment; Perfusion

619. **Answer:** 1

**Rationale:** Sinus tachycardia has the characteristics of normal sinus rhythm, including a regular PP interval and normal-width PR and QRS intervals; however, the rate is the differentiating factor. In sinus tachycardia, the atrial and ventricular rates are greater than 100 beats per minute.

**Test-Taking Strategy:** Focus on the subject, interpreting a cardiac rhythm. Eliminate sinus bradycardia and normal sinus rhythm first, because the ventricular rate is 110 beats per minute. Next eliminate sinus dysrhythmia, because this is an irregular rhythm, with changing PP and RR intervals.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Cardiovascular

**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias

**Priority Concepts:** Perfusion; Safety

**Reference:** Lewis et al. (2014), p. 803.

620. **Answer:** 1

**Rationale:** An expected outcome of aortoiliac bypass graft surgery is warmth, redness, and edema in the surgical extremity because of increased blood flow. The remaining options are incorrect interpretations.
Test-Taking Strategy: Focus on the subject, expected outcomes following aortoiliac bypass graft surgery. Venous complications from immobilization resulting from surgery would not be apparent within 4 hours, so eliminate option 4. From the remaining options, note that the pedal pulse is unchanged from admission and think about the effects of sudden reperfusion in an ischemic limb. There would be redness from new blood flow and edema from the sudden change in pressure in the blood vessels.

Level of Cognitive Ability: Synthesizing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Cardiovascular
Health Problem: Adult Health: Cardiovascular: Vascular disorders
Priority Concepts: Clinical Judgment; Perfusion

621. Answer: 3

Rationale: Following pericardiocentesis, the client usually expresses immediate relief. Heart sounds are no longer muffled or distant and blood pressure increases. Distended neck veins are a sign of increased venous pressure, which occurs with cardiac tamponade.

Test-Taking Strategy: Focus on the subject, expected outcome following pericardiocentesis, and note the strategic word, effective. Successful therapy is measured by the disappearance of the original signs and symptoms of cardiac tamponade. This will direct you to the correct option.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Complex Care: Emergency Situations/Management
Health Problem: Adult Health: Cardiovascular: Cardiac Tamponade
Priority Concepts: Evidence; Perfusion

622. Answer: 4

Rationale: Following abdominal aortic aneurysm resection or repair, the nurse monitors the client for signs of acute kidney injury. Acute kidney injury can occur because often much blood is lost during the surgery and, depending on the aneurysm location, the renal arteries may be hypoperfused for a short period during surgery. Normal reference levels are BUN 10 to 20 mg/dL (3.6 to 7.1 mmol/L), and creatinine 0.6 to 1.2 mg/dL (53 to 106 mcmol/L) for males and 0.5 to 1.1 mg/dL (44 to 97 mcmol/L) for females. Continuing to monitor urine output or checking other parameters can wait. Urine output lower than 30 mL/hr is reported to the PHCP for urgent treatment.

Test-Taking Strategy: Note the strategic word, priority. Focus on the data in the question and the abnormal assessment data. This question indicates elevations in blood urea nitrogen and creatinine levels and a significant drop in hourly urine
output. These assessment findings should direct you to an option that includes active collaboration with the PHCP.

**Level of Cognitive Ability:** Synthesizing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Complex Care—Emergency Situations/Management  
**Health Problem:** Adult Health: Cardiovascular: Vascular Disorders  
**Priority Concepts:** Clinical Judgment; Perfusion  
**Reference:** Lewis et al. (2014), pp. 841-843.

623. **Answer:** 4

**Rationale:** Variant angina, or Prinzmetal's angina, is prolonged and severe and occurs at the same time each day, most often at rest. The pain is a result of coronary artery spasm. The treatment of choice is usually a calcium channel blocker, which relaxes and dilates the vascular smooth muscle, thus relieving the coronary artery spasm in variant angina. Adverse effects can include peripheral edema, hypotension, bradycardia, and heart failure. Grapefruit juice interacts with calcium channel blockers and should be avoided. If bradycardia occurs, the client should contact the primary health care provider or cardiologist. Clients should also be taught to change positions slowly to prevent orthostatic hypotension. Physical exertion does not cause this type of angina; therefore, the client should be able to continue morning walks with her or his spouse.

**Test-Taking Strategy:** Note the strategic words, *need for further teaching*, and focus on the data in the question. These words indicate a negative event query and the need to select the incorrect client statement. Recall that walking is a low-impact exercise and is usually recommended for clients with heart problems.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Cardiovascular  
**Health Problem:** Adult Health: Cardiovascular: Coronary artery disease  
**Priority Concepts:** Client Education; Safety  

624. **Answer:** 3

**Rationale:** Ventricular fibrillation is characterized by irregular chaotic undulations of varying amplitudes. Ventricular fibrillation has no measurable rate and no visible P waves or QRS complexes and results from electrical chaos in the ventricles.

**Test-Taking Strategy:** Focus on the subject, the characteristics of ventricular fibrillation. Note the words, *no definable QRS complexes*. The lack of visible QRS complexes eliminates atrial fibrillation and ventricular tachycardia. Recalling that asystole is lack of any electrical activity of the heart will direct you to the correct option.

CHAPTER 53

Cardiovascular Medications

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Clotting; Perfusion

I. Anticoagulants (Box 53-1)
   A. Description
      1. Anticoagulants prevent the extension and formation of clots by inhibiting factors in the clotting cascade and decreasing blood coagulability.
      2. Anticoagulants are administered when there is evidence of or likelihood of clot formation—myocardial infarction, unstable angina, atrial fibrillation, deep vein thrombosis, pulmonary embolism, and the presence of mechanical heart valves.
      3. Anticoagulants are contraindicated with active bleeding (except for disseminated intravascular coagulation), bleeding disorders or blood dyscrasias, ulcers, liver and kidney disease, and hemorrhagic brain injuries (Box 53-2).
   B. Side and adverse effects
      1. Hemorrhage
      2. Hematuria
      3. Epistaxis
      4. Ecchymosis
      5. Bleeding gums
      6. Thrombocytopenia
      7. Hypotension
   C. Heparin sodium
      1. Description
         a. Heparin prevents thrombin from converting fibrinogen to fibrin.
         b. Heparin prevents thromboembolism.
c. The therapeutic dose does not dissolve clots but prevents new thrombus formation.

2. Blood levels

a. The normal activated partial thromboplastin time (aPTT) is 30 to 40 seconds (conventional and SI units) in most laboratories (values depend on reagent and instrumentation used).

b. To maintain a therapeutic level of anticoagulation when the client is receiving a continuous infusion of heparin, the aPTT should be 1.5 to 2.5 times the normal value. Some agencies use 2 different protocols, a high-intensity protocol such as for acute coronary syndrome and a low-intensity protocol such as for venous thromboembolism prophylaxis, and the dosages and recommended aPTT ranges are slightly different for the two protocols.

c. Activated partial thromboplastin time therapy should be measured every 4 to 6 hours during initial continuous infusion therapy or until the client has been therapeutic for a specified time frame and then daily per agency policy.

d. If the aPTT is too long, per agency procedure, the dosage should be lowered.

e. If the aPTT is too short, per agency procedure, the dosage should be increased.

3. Interventions

a. Monitor aPTT.

b. Monitor platelet count.

c. Observe for bleeding gums, bruises, nosebleeds, hematuria, hematemesis, occult blood in the stool, and petechiae.

d. Instruct the client regarding measures
to prevent bleeding.
e. The antidote to heparin is protamine sulfate.
f. When administering heparin subcutaneously, inject into the abdomen with a ⅝-inch (16-mm) needle (25 to 28 gauge) at a 90-degree angle and do not aspirate or rub the injection site.
g. Continuous IV infusions must be run on an infusion pump to ensure a precise rate of delivery.

D. Enoxaparin or Rivaroxaban—low-molecular-weight heparins
   1. Description: Enoxaparin and rivaroxaban have the same mechanism of action and use as heparin but are not interchangeable with heparin; they have longer half-lives than heparin does.
   2. Interventions
   a. Administer enoxaparin only to the recumbent client by subcutaneous injection into the anterolateral or posterolateral abdominal wall; do not expel the air bubble from the prefilled syringe or aspirate during injection.
   b. Rivaroxaban is a taken orally, once daily.
   c. Monitor results of the Anti-Xa assay. The therapeutic range for anticoagulation is 0.5 to 1.2 IU/mL (conventional and SI units). Observe for bleeding.
   d. The antidote to low-molecular-weight heparins is protamine sulfate.

E. Warfarin sodium
   1. Description
   a. Warfarin suppresses coagulation by acting as an antagonist of vitamin K by inhibiting 4 dependent clotting factors (X, IX, VII, and II).
   b. Warfarin prolongs clotting time and is monitored by the prothrombin time (PT) and the international normalized ratio (INR).
c. It is used for long-term anticoagulation and is used mainly to prevent thromboembolic conditions such as thrombophlebitis, pulmonary embolism, and embolism formation caused by atrial fibrillation, thrombosis, myocardial infarction, or heart valve damage.

2. Blood levels
   a. The normal PT is 11 to 12.5 seconds (conventional and SI units).
   b. Warfarin sodium prolongs the PT; the therapeutic range is 1.5 to 2 times the control value.

3. INR
   a. The normal INR is 0.81 to 1.2 (0.81 to 1.2).
   b. The INR is determined by multiplying the observed PT ratio (the ratio of the client’s PT to a control PT) by a correction factor specific to a particular thromboplastin preparation used in the testing.
   c. The treatment goal of warfarin sodium is to raise the INR to an appropriate value.
   d. An INR of 2 to 3 is appropriate for standard warfarin therapy; an INR of 3 to 4.5 is appropriate for high-dose warfarin therapy.
   e. If the PT value is longer than 30 seconds and the INR is greater than 3.0 in a client receiving standard warfarin therapy, initiate bleeding precautions.
   f. If the INR is below the recommended range, warfarin sodium should be increased.
   g. Clients may sometimes be prescribed “bridge therapy,” whereby heparin sodium is used concurrently with warfarin sodium until the INR reaches the recommended range. Once this occurs, the heparin is discontinued.

4. Interventions
   a. Monitor PT and INR.
b. Observe for bleeding gums, bruises, nosebleeds, hematuria, hematemesis, occult blood in the stool, and petechiae.
c. Instruct the client regarding diet and measures to prevent bleeding.
d. The antidote for warfarin is phytonadione.

F. Dabigatran etexilate
   1. Description
      a. Dabigatran etexilate works through direct inhibition of thrombin, preventing the conversion of fibrinogen into fibrin and activation of factor XIII.
      b. Current approved use is for clot prevention associated with nonvalvular atrial fibrillation.
      c. It is administered in a fixed dose twice daily.

   2. Blood levels: No blood testing is required.
   3. Interventions: Same as for warfarin, except no routine monitoring is required.

II. Thrombolytic Medications (Box 53-3)
   A. Description
      1. Thrombolytic medications activate plasminogen; plasminogen generates plasmin (the enzyme that dissolves clots).
      2. Thrombolytic medications are used early in the course of myocardial infarction (within 4 to 6 hours of the onset of the infarct) to restore blood flow, limit myocardial damage, preserve left ventricular function, and prevent death.
      3. Thrombolytics are also used in arterial thrombosis, deep vein thrombosis, occluded shunts or catheters, and pulmonary emboli.

   B. Contraindications
      1. Active internal bleeding
      2. History of hemorrhagic stroke
      3. Intracranial problems, including trauma
      4. Intracranial or intraspinal surgery within the previous 2 months
      5. Thoracic, pelvic, or abdominal surgery in the previous 10 days
      6. History of hepatic or renal disease
7. Uncontrolled hypertension
8. Recent, prolonged cardiopulmonary resuscitation
9. Known allergy to the product or its preservatives

C. Side and adverse effects
1. Bleeding
2. Dysrhythmias
3. Allergic reactions

D. Interventions
1. Determine aPTT, PT, fibrinogen level, hematocrit, and platelet count.
2. Monitor vital signs.
3. Assess pulses.
4. Monitor for bleeding and check all excretions for occult blood.
5. Monitor for neurological changes such as slurred speech, lethargy, confusion, and hemiparesis.
6. Monitor for hypotension and tachycardia.
7. Avoid injections and venipunctures if possible.
8. Apply direct pressure over a puncture site for 20 to 30 minutes.
9. Handle the client gently and as little as possible when moving.
10. Instruct the client to use an electric razor for shaving and to brush teeth gently.
11. Withhold the medication if bleeding develops, and notify the primary health care provider (PHCP).
12. Antidote: Aminocaproic acid is the antidote.

III. Antiplatelet Medications (Box 53-4)
A. Description
1. Antiplatelet medications inhibit the aggregation of platelets in the clotting process, thereby prolonging the bleeding time.
2. Antiplatelet medications may be used with anticoagulants.
3. Used in the prophylaxis of long-term complications following myocardial infarction, coronary revascularization, stents, and stroke.
4. These medications are contraindicated in those with bleeding disorders and known sensitivity.
B. Side and adverse effects

1. Bruising
2. Hematuria
3. Gastrointestinal bleeding
4. Tarry stools

C. Interventions

1. A blood test may be prescribed to determine the client’s sensitivity to the medication before beginning administration.
2. Monitor vital signs.
3. Instruct the client to take medication with food if gastrointestinal upset occurs.
5. Instruct the client to monitor for side and adverse effects and in the measures to prevent bleeding.

IV. Positive Inotropic and Cardiotonic Medications (Box 53-5)

A. Description

1. These medications stimulate myocardial contractility and produce a positive inotropic effect.
2. These medications are used for short-term management of advanced heart failure; the increase in myocardial contractility improves cardiac, peripheral, and kidney function by increasing cardiac output, decreasing preload, improving blood flow to the periphery and kidneys, decreasing edema, and increasing fluid excretion. As a result, fluid retention in the lungs and extremities is decreased (Fig. 53-1).

B. Side and adverse effects

1. Dysrhythmias
2. Hypotension
3. Thrombocytopenia
4. Hepatotoxicity manifested by elevated liver enzyme levels
5. Hypersensitivity manifested by wheezing, shortness of breath, pruritus, urticaria, clammy skin, and flushing

C. Interventions

1. Positive inotropic and cardiotonic medications are used for intravenous (IV) administration.
   a. For continuous IV infusion, administer with an infusion pump.
   b. Stop the infusion if the client’s blood pressure (BP) drops or dysrhythmias occur.
2. Monitor the apical pulse and BP.
4. Assess lung sounds for wheezing and crackles.
5. Monitor for edema.
6. Monitor for relief of heart failure as noted by reduction in edema and lessening of dyspnea, orthopnea, and fatigue.
7. Monitor electrolyte and liver enzyme levels, platelet count, and renal function studies; the medications may decrease potassium and increase liver enzyme levels; continuous electrocardiographic monitoring is done during administration.

V. Cardiac Glycosides

A. Digoxin

1. Description

a. Cardiac glycosides inhibit the sodium-potassium pump, thus increasing intracellular calcium, which causes the heart muscle fibers to contract more efficiently.
b. Cardiac glycosides produce a positive inotropic action, which increases the force of myocardial contractions.
c. Cardiac glycosides produce a negative chronotropic action, which slows the heart rate.
d. Cardiac glycosides produce a negative dromotropic action that slows conduction velocity through the atrioventricular (AV) node.
e. The increase in myocardial contractility increases cardiac, peripheral, and kidney function by increasing cardiac output, decreasing preload, improving blood flow to the periphery and kidneys, decreasing edema, and increasing fluid excretion; as a result, fluid retention in the lungs and extremities is decreased.
f. Cardiac glycosides are used second-line for heart failure (medications affecting the renin-angiotensin-aldosterone system are used more often) and cardiogenic shock, atrial tachycardia, atrial fibrillation, and atrial flutter; they are used less frequently for rate control in atrial dysrhythmias (beta
blockers and calcium channel blockers are used more often).
g. These medications are contraindicated in those with ventricular dysrhythmias and second- or third-degree heart block. They should be used with caution in clients with renal disease, hypothyroidism, and hypokalemia.

2. Side and adverse effects

a. Anorexia, nausea, vomiting, diarrhea
b. Bradycardia
c. Visual disturbances: Diplopia, blurred vision, yellow vision, photophobia
d. Headache
e. Fatigue, weakness
f. Drowsiness

Early signs of digoxin toxicity present as gastrointestinal manifestations (anorexia, nausea, vomiting, diarrhea); then, heart rate abnormalities and visual disturbances appear.

3. Interventions

a. Monitor for toxicity as evidenced by anorexia, nausea, vomiting, visual disturbances (blurred or yellow vision), and dysrhythmias.
b. Monitor serum digoxin level, electrolyte levels, and renal function test results.
c. The optimal therapeutic range for digoxin is 0.5 to 2.0 ng/dL (0.63 to 2.56 nmol/L). However, a level on the low end of normal may be preferred to avoid toxicity.
d. An increased risk of toxicity exists in clients with hypercalcemia, hypokalemia, hypomagnesemia, or hypothyroidism.
e. Monitor the potassium level; if hypokalemia occurs (potassium lower than 3.5 mEq/L [3.5 mmol/L]), notify the PHCP.
f. Instruct the client to avoid over-the-counter medications.
g. Monitor the client taking a potassium-losing diuretic or corticosteroids closely for hypokalemia, because the hypokalemia can cause digoxin toxicity.

h. Note that older clients are more sensitive to digoxin toxicity.

i. Advise the client to eat foods high in potassium, such as fresh and dried fruits, fruit juices, vegetables, and potatoes.

j. Monitor the apical pulse for 1 full minute; if the apical pulse rate is lower than 60 beats per minute, the medication should be withheld and the PHCP notified.

k. Teach the client how to measure the pulse and to notify the PHCP if the pulse rate is lower than 60 or more than 100 beats per minute.

l. Teach the client the signs and symptoms of toxicity.

m. Antidote: Digoxin immune Fab is used in extreme toxicity.

VI. Antihypertensive Medications: Diuretics (Box 53-6)

A. Thiazide diuretics (Box 53-7)

1. Description

a. Thiazide diuretics increase sodium and water excretion by inhibiting sodium reabsorption in the distal tubule of the kidney.

b. Used for hypertension and peripheral edema

c. Not effective for immediate diuresis

d. Used in clients with normal renal function (contraindicated in clients with renal failure)

e. Thiazide diuretics should be used with caution in the client taking lithium, because lithium toxicity can occur, and in the client taking digoxin, corticosteroids, or hypoglycemic medications.

2. Side and adverse effects

a. Hypercalcemia, hyperglycemia, hyperuricemia

b. Hypokalemia, hyponatremia
3. Interventions

a. Monitor vital signs.
b. Monitor weight.
c. Monitor urine output.
d. Monitor electrolytes, glucose, calcium, blood urea nitrogen (BUN), creatinine, and uric acid levels.
e. Check peripheral extremities for edema.
f. Monitor for signs of digoxin or lithium toxicity if the client is taking these medications.
g. Instruct the client to take the medication in the morning to avoid nocturia and sleep interruption.
h. Instruct the client in how to record the BP.
i. Instruct the client to eat foods high in potassium.
j. Instruct the client in how to take potassium supplements if prescribed.
k. Instruct the client to take medication with food to avoid gastrointestinal upset.
l. Instruct the client to change positions slowly to prevent orthostatic hypotension.
m. Instruct the client to use sunscreen when in direct sunlight because of increased photosensitivity.
n. Instruct the client with diabetes mellitus to have the blood glucose level checked periodically.

B. Loop diuretics (Box 53-8)

1. Description

a. Loop diuretics inhibit sodium and chloride reabsorption from the loop of Henle and the distal tubule.
b. Loop diuretics have little effect on the blood glucose level; however, they cause depletion of water and
electrolytes, increased uric acid levels, and the excretion of calcium.
c. Loop diuretics are more potent than thiazide diuretics, causing rapid diuresis, and thus decreasing vascular fluid volume, cardiac output, and BP.
d. Used for hypertension, pulmonary edema, edema associated with heart failure, hypercalcemia, and renal disease
e. Use loop diuretics with caution in the client taking digoxin or lithium and in the client taking aminoglycosides, anticoagulants, corticosteroids, or amphotericin B.

2. Side and adverse effects
a. Hypokalemia, hyponatremia, hypocalcemia, hypomagnesemia
b. Thrombocytopenia
c. Hyperuricemia
d. Orthostatic hypotension
e. Rash
f. Ototoxicity and deafness
g. Thiamine deficiency
h. Dehydration

3. Interventions: See section VI, A, 3 (Interventions for thiazide diuretics).
a. Monitor electrolytes, calcium, magnesium, BUN, creatinine, and uric acid levels.
b. Administer IV furosemide slowly over 1 to 2 minutes, because hearing loss can occur if injected rapidly.

C. Osmotic diuretics: See Chapter 59.

D. Potassium-retaining (sparing) diuretics (Box 53-9)

1. Description
a. Potassium-retaining (sparing) diuretics act on the distal tubule to promote sodium and water excretion and potassium retention.
b. Used for edema and hypertension, to increase urine output, and to treat fluid retention and overload associated with heart failure, ascites resulting
from cirrhosis or nephrotic syndrome, and diuretic-induced hypokalemia.
c. Potassium-retaining (sparing) diuretics are contraindicated in severe kidney or hepatic disease and in severe hyperkalemia.
d. Potassium-retaining (sparing) diuretics should be used with caution in the client with diabetes mellitus, taking antihypertensives or lithium, or taking angiotensin-converting enzyme inhibitors or potassium supplements, because hyperkalemia can result.

2. Side and adverse effects
   a. Hyperkalemia
   b. Nausea, vomiting, diarrhea
   c. Rash
   d. Dizziness, weakness
   e. Headache
   f. Dry mouth
   g. Photosensitivity
   h. Anemia
   i. Thrombocytopenia

3. Interventions
   a. Monitor vital signs.
   b. Monitor urine output.
   c. Monitor for signs and symptoms of hyperkalemia such as nausea; diarrhea; abdominal cramps; tachycardia followed by bradycardia; tall, peaked T waves on the electrocardiogram; and oliguria.
   d. Monitor for a potassium level greater than 5.0 mEq/L (5.0 mmol/L), which indicates hyperkalemia.
   e. Instruct the client to avoid foods high in potassium.
   f. Instruct the client to avoid exposure to direct sunlight.
   g. Instruct the client to monitor for signs
of hyperkalemia.
h. Instruct the client to avoid salt
substitutes because they contain
potassium.
i. Instruct the client to take the medication
with or after meals to decrease
gastrointestinal irritation.

VII. Peripherally Acting α-Adrenergic Blockers (Box 53-10)

A. Description

1. These medications decrease sympathetic
vasoconstriction by reducing the effects of
norepinephrine at peripheral nerve endings, resulting
in vasodilation and decreased BP.
2. These medications are used to maintain renal blood
flow.
3. These medications are used to treat hypertension.

B. Side and adverse effects

1. Orthostatic hypotension
2. Reflex tachycardia
3. Sodium and water retention
4. Edema
5. Weight gain
6. Gastrointestinal disturbances
7. Drowsiness
8. Nasal congestion

C. Interventions

1. Monitor vital signs.
2. Monitor for fluid retention and edema.
3. Instruct the client to change positions slowly to
prevent orthostatic hypotension.
4. Instruct the client in how to monitor the BP.
5. Instruct the client to monitor for edema.
6. Instruct the client to decrease salt intake.
7. Instruct the client to avoid over-the-counter
medications.

VIII. Centrally Acting Sympatholytics (Adrenergic Blockers) (Box 53-11)

A. Description

1. Centrally acting sympatholytics stimulate α-receptors
in the central nervous system to inhibit
vasoconstriction, thus reducing peripheral resistance.
2. Used to treat hypertension
3. Contraindicated in impaired liver function

B. Side and adverse effects

1. Sodium and water retention
2. Edema
3. Drowsiness, dizziness
4. Dry mouth
5. Hypotension
6. Bradycardia
7. Impotence
8. Depression

C. Interventions

1. Monitor vital signs.
2. Instruct the client not to discontinue medication, because abrupt withdrawal can cause severe rebound hypertension.
3. Monitor liver function tests.

IX. Angiotensin-Converting Enzyme (ACE) Inhibitors and Angiotensin II Receptor Blockers (ARBs) (Box 53-12)

A. Description

1. ACE inhibitors prevent peripheral vasoconstriction by blocking conversion of angiotensin I to angiotensin II (AII).
2. ARBs prevent peripheral vasoconstriction and secretion of aldosterone and block the binding of AII to type 1 AII receptors.
3. These medications are used to treat hypertension and heart failure; also, ACE inhibitors are administered for their cardioprotective effect after myocardial infarction.
4. Avoid use with potassium supplements and potassium-retaining (sparing) diuretics.

B. Side and adverse effects

1. Nausea, vomiting, diarrhea
2. Persistent dry cough (ACE inhibitors)
3. Hypotension
4. Hyperkalemia
5. Tachycardia
6. Headache
7. Dizziness, fatigue
8. Insomnia
9. Hypoglycemic reaction in the client with diabetes mellitus
10. Bruising, petechiae, bleeding
11. Diminished taste (ACE inhibitors)

A persistent dry cough is a common complaint for those taking an ACE inhibitor, but this often subsides after a few weeks. Instruct the client to contact the PHCP if this occurs and persists.

C. Interventions
1. Monitor vital signs.
2. Monitor white blood cells, and protein, albumin, BUN, creatinine, and potassium levels.
4. If captopril is prescribed, instruct the client to take the medication 20 to 60 minutes before a meal.
5. Monitor for bruising, petechiae, or bleeding with captopril.
6. Instruct the client not to discontinue medications, because rebound hypertension can occur.
7. Instruct the client not to take over-the-counter medications.
8. Instruct the client in how to take the BP.
9. Inform the client that the taste of food may be diminished during the first month of therapy.
10. Instruct the client to report adverse effects to the PHCP.

X. Antianginal Medications (Box 53-13)

A. Nitrates (see Priority Nursing Actions)

Priority Nursing Actions

Chest Pain in a Hospitalized Client with Cardiac Disease
1. Quickly assess the client, specifically characteristics of pain, heart rate and rhythm, and blood pressure (BP).
2. Administer a nitroglycerin tablet sublingually.
3. Stay with the client.
4. Reassess in 5 minutes.
5. Administer another nitroglycerin tablet sublingually if pain is not relieved and the BP is stable.
6. Reassess in 5 minutes.
7. Administer a third nitroglycerin tablet sublingually if pain is not relieved and the BP is stable.
8. Reassess in 5 minutes; contact the primary health care provider (PHCP) if the third nitroglycerin tablet does not relieve the pain.

Reference

1. Description
   a. Nitrates produce vasodilation, decrease preload and afterload, and reduce myocardial oxygen consumption.
   b. Contraindicated in the client with significant hypotension, increased intracranial pressure, or severe anemia and in those taking medication to treat erectile dysfunction

1781
c. Should be used with caution with severe renal or hepatic disease
d. Avoid abrupt withdrawal of long-acting preparations to prevent the rebound effect of severe pain from myocardial ischemia.

2. Side and adverse effects
   a. Headache
   b. Orthostatic hypotension
   c. Dizziness, weakness
   d. Faintness
   e. Flushing or pallor
   f. Dry mouth
   g. Reflex tachycardia

3. Sublingual medications
   a. Monitor vital signs.
   b. Offer sips of water before giving, because dryness may inhibit medication absorption.
   c. Instruct the client to place under the tongue and leave until fully dissolved.
   d. Instruct the client not to swallow the medication.
   e. Instruct the at-home client to take 1 tablet for pain and to immediately contact emergency medical services if pain is not relieved; in the hospitalized client, 1 tablet is administered every 5 minutes for a total of 3 doses and the PHCP is notified immediately if pain is not relieved following the 3 doses (the BP is checked before each administration).
   f. Inform the client that a stinging or burning sensation may indicate that the tablet is fresh.
   g. Instruct the client to store medication in a dark, tightly closed bottle.
   h. Instruct the client to take acetaminophen for a headache.

4. Translingual medications (spray)
   a. Instruct the client to direct the spray against the oral mucosa.
   b. Instruct the client to avoid inhaling the spray.

5. Sustained-released medications: Instruct the client to swallow and not to chew or crush the medication.

6. Transdermal patch
   a. Instruct the client to apply the patch to a hairless area, using a new patch and different site each day.
   b. As prescribed, instruct the client to remove the patch after 12 to 14 hours, allowing 10 to 12 “patch-free” hours each day to prevent tolerance.
7. Topical ointments
   a. Instruct the client to remove the ointment on the skin
      from the previous dose.
   b. Instruct the client to squeeze a ribbon of ointment of
      the prescribed length onto the applicator or dose-
      measuring paper.
   c. Instruct the client to spread the ointment over a 2.5- by
      3.5-inch (6.5 by 9 cm) area and cover with plastic
      wrap, using the chest, back, abdomen, upper arm, or
      anterior thigh (avoid hairy areas).
   d. Instruct the client to rotate sites and to avoid
      touching the ointment when applying.

8. Patches and ointments
   a. Wear gloves when applying.
   b. Do not apply on the chest in the area of defibrillator-
      cardioverter pad placement, because skin burns can
      result if the pads need to be used.

   ! Instruct the client using nitroglycerin tablets to check the
   expiration date on the medication bottle, because expiration may occur
   within 6 months of obtaining the medication. The tablets will not relieve
   chest pain if they have expired.

XI. β-Adrenergic Blockers (Box 53-14)
A. Description
   1. β-Adrenergic blockers inhibit response to β-adrenergic
      stimulation, thus decreasing cardiac output.
   2. They block the release of catecholamines, epinephrine,
      and norepinephrine, thus decreasing the heart rate
      and BP; they also decrease the workload of the heart
      and decrease oxygen demands.
   3. Used for angina, dysrhythmias, hypertension,
      migraine headaches, prevention of myocardial
      infarction, and glaucoma
   4. β-Adrenergic blockers are contraindicated in the client
      with asthma, bradycardia, heart failure (with
      exceptions), severe renal or hepatic disease,
      hyperthyroidism, or stroke; carvedilol, metoprolol,
      and bisoprolol have been approved for use in heart
      failure once the client has been stabilized by ACE
      inhibitor and diuretic therapy.
   5. β-Adrenergic blockers should be used with caution in
      the client with diabetes mellitus, because the
      medication may mask symptoms of hypoglycemia.
   6. β-Adrenergic blockers should be used with caution in
      the client taking antihypertensive medications.
B. Side and adverse effects

1. Bradycardia
2. Bronchospasm
3. Hypotension
4. Weakness, fatigue
5. Nausea, vomiting
6. Dizziness
7. Hyperglycemia
8. Agranulocytosis
9. Behavioral or psychotic response
10. Depression
11. Nightmares

C. Interventions

1. Monitor vital signs.
2. Withhold the medication if the pulse or BP is not within the prescribed parameters.
3. Monitor for signs of heart failure or worsening heart failure.
4. Assess for respiratory distress and for signs of wheezing and dyspnea.
5. Instruct the client to report dizziness, lightheadedness, or nasal congestion.
6. Instruct the client not to stop the medication, because rebound hypertension, rebound tachycardia, or an anginal attack can occur.
7. Advise the client taking insulin that the β-adrenergic blocker can mask early signs of hypoglycemia, such as tachycardia and nervousness.
8. Instruct the client taking insulin to monitor the blood glucose level.
9. Instruct the client in how to take pulse and BP.
10. Instruct the client to change positions slowly to prevent orthostatic hypotension.
11. Instruct the client to avoid over-the-counter medications, especially cold medications and nasal decongestants.

XII. Calcium Channel Blockers (Box 53-15)

A. Description

1. Calcium channel blockers decrease cardiac contractility (negative inotropic effect by relaxing smooth muscle) and the workload of the heart, thus decreasing the need for oxygen.
2. Calcium channel blockers promote vasodilation of the coronary and peripheral vessels.
3. Used for angina, dysrhythmias, or hypertension
4. Should be used with caution in the client with heart failure, bradycardia, or atrioventricular block

B. Side and adverse effects

1. Bradycardia
2. Hypotension
3. Reflex tachycardia as a result of hypotension
4. Headache
5. Dizziness, lightheadedness
6. Fatigue
7. Peripheral edema
8. Constipation
9. Flushing of the skin
10. Changes in liver and kidney function

C. Interventions

1. Monitor vital signs.
3. Monitor liver enzyme levels.
4. Monitor kidney function tests.
5. Instruct the client not to discontinue the medication.
6. Instruct the client in how to take the pulse.
7. Instruct the client to notify the PHCP if dizziness or fainting occurs.
8. Instruct the client not to crush or chew sustained-release tablets.

XIII. Peripheral Vasodilators (Box 53-16)

A. Description

1. Peripheral vasodilators decrease peripheral resistance by exerting a direct action on the arteries or on the arteries and the veins.
2. These medications increase blood flow to the extremities and are used in peripheral vascular disorders of venous and arterial vessels.
3. Peripheral vasodilators are most effective for disorders resulting from vasospasm (Raynaud’s disease).
4. These medications may decrease some symptoms of cerebral vascular insufficiency.

B. Side and adverse effects

1. Lightheadedness, dizziness
2. Orthostatic hypotension
3. Tachycardia
4. Palpitations
5. Flushing
6. Gastrointestinal distress
C. Interventions

1. Monitor vital signs, especially the BP and the heart rate.
2. Monitor for orthostatic hypotension and tachycardia.
3. Monitor for signs of inadequate blood flow to the extremities, such as pallor, feeling cold, and pain.
4. Instruct the client that it may take up to 3 months for a desired therapeutic response.
5. Advise the client not to smoke, because smoking increases vasospasm.
6. Instruct the client to avoid aspirin or aspirin-like compounds unless approved by the PHCP.
7. Instruct the client to take the medication with meals if gastrointestinal disturbances occur.
8. Instruct the client to avoid alcohol, because it may cause a hypotensive reaction.
9. Encourage the client to change positions slowly to avoid orthostatic hypotension.

XIV. Direct-Acting Arteriolar Vasodilators (Box 53-17)

A. Description

1. Direct-acting vasodilators relax the smooth muscles of the blood vessels, mainly the arteries, causing vasodilation; with vasodilation, the BP drops and sodium and water are retained, resulting in peripheral edema (diuretics may be given to decrease the edema).
2. Direct-acting vasodilators promote an increase in blood flow to the brain and kidneys.
3. These medications are used in the client with moderate to severe hypertension and for acute hypertensive emergencies.

B. Side and adverse effects

1. Hypotension
2. Reflex tachycardia caused by vasodilation and the drop in BP
3. Palpitations
4. Edema
5. Dizziness
6. Headaches
7. Nasal congestion
8. Gastrointestinal bleeding
9. Neurological symptoms
10. Confusion
11. With sodium nitroprusside, cyanide toxicity and thiocyanate toxicity can occur.
C. Interventions

1. Monitor vital signs, especially BP.
2. Sodium nitroprusside
   a. Monitor cyanide and thiocyanate levels.
   b. Protect from light because the medication decomposes.
   c. When administering, solution must be covered by a dark bag provided by the manufacturer and is stable for 24 hours.
   d. Discard if the medication is red, green, or blue.

XV. Miscellaneous Vasodilator

A. Description
   1. Nesiritide
      a. Recombinant version of human B-type natriuretic peptide that vasodilates arteries and veins
      b. Used for the treatment of decompensated heart failure
   2. Side and adverse effects
      a. Hypotension
      b. Confusion
      c. Dizziness
      d. Dysrhythmias
   3. Interventions
      a. Administer by continuous IV infusion via infusion device
      b. Monitor BP, cardiac rhythm, urine output, and body weight.
      c. Monitor for signs of resolving heart failure.

XVI. Antidysrhythmic Medications

A. Description: Antidysrhythmic medications suppress dysrhythmias by inhibiting abnormal pathways of electrical conduction through the heart.
B. Class I antidysrhythmics are sodium channel blockers, class II are beta blockers, class III are potassium channel blockers (medications that delay repolarization), and class IV are calcium channel blockers.
C. Class IA antidysrhythmics
   1. Disopyramide
   2. Procainamide
   3. Quinidine sulfate

D. Class IB antidysrhythmics
   1. Lidocaine
   2. Mexiletine hydrochloride
   3. Phenytoin

E. Class IC antidysrhythmics
   1. Flecainide acetate
   2. Propafenone hydrochloride

3. Side and adverse effects: Class I
   antidysrhythmics
   a. Hypotension
   b. Heart failure
   c. Worsened or new dysrhythmias
   d. Nausea, vomiting, or diarrhea

F. Class II antidysrhythmics
   1. Acebutolol
   2. Esmolol
   3. Propranolol
   4. Metoprolol
   5. Nadolol
   6. Atenolol

7. Side and adverse effects: Class II
   antidysrhythmics
   a. Dizziness
   b. Fatigue
   c. Hypotension
   d. Bradycardia
   e. Heart failure
   f. Dysrhythmias
   g. Heart block
   h. Bronchospasms
   i. Gastrointestinal distress

G. Class III antidysrhythmics
   1. Amiodarone
   2. Dofetilide
   3. Ibutilide
   4. Sotalol

5. Side and adverse effects: Class III
   antidysrhythmics
   a. Hypotension
   b. Bradycardia

1788
c. Nausea, vomiting

d. Amiodarone hydrochloride may cause pulmonary fibrosis, photosensitivity, bluish skin discoloration, corneal deposits, peripheral neuropathy, tremor, poor coordination, abnormal gait, and hypothyroidism.

e. The electrocardiogram should be monitored for clients receiving amiodarone or dofetilide, because they may prolong the QT interval, potentially leading to torsades de pointes.

H. Class IV antidysrhythmics
   1. Verapamil
   2. Diltiazem

   3. Side and adverse effects: Class IV antidysrhythmics
      a. Dizziness
      b. Hypotension
      c. Bradycardia
      d. Edema
      e. Constipation

I. Other antidysrhythmics
   1. Adenosine
   2. Digoxin

J. Interventions for antidysrhythmics
   1. Monitor heart rate, respiratory rate, and BP.
   3. Provide continuous cardiac monitoring.
   4. Maintain therapeutic serum medication levels.
   5. Before administering lidocaine, always check the vial label to prevent administering a form that contains epinephrine or preservatives, because these solutions are used for local anesthesia only.
   6. Do not administer antidysrhythmics with food, because food may affect absorption.
   7. Mexiletine may be administered with food or antacids to reduce gastrointestinal distress.
   8. Always administer IV antidysrhythmics via an infusion pump.
   9. Monitor for signs of fluid retention such as weight gain, peripheral edema, or shortness of breath.
   10. Advise the client to limit fluid and salt intake to minimize fluid retention.
11. Monitor respiratory, thyroid, and neurological functions.
12. Instruct the client to change positions slowly to minimize orthostatic hypotension.
13. Instruct the client taking amiodarone to use sunscreen and protective clothing to prevent photosensitivity reactions.
14. Encourage the client to increase fiber intake to prevent constipation.

XVII. Adrenergic Agonists (Box 53-18)
A. Dobutamine
   1. Increases myocardial force and cardiac output through stimulation of β-receptors
   2. Used in clients with heart failure and for clients undergoing cardiopulmonary bypass surgery

B. Dopamine
   1. Increases BP and cardiac output through positive inotropic action and increases renal blood flow through its action on α- and β-receptors
   2. Used to treat mild kidney failure caused by low cardiac output

C. Epinephrine
   1. Used for cardiac stimulation in cardiac arrest
   2. Used for bronchodilation in asthma or allergic reactions
   3. Produces mydriasis
   4. Produces local vasoconstriction when combined with local anesthetics and prolongs anesthetic action by decreasing blood flow to the site

D. Norepinephrine
   1. Stimulates the heart in cardiac arrest
   2. Vasoconstricts and increases the BP in hypotension and shock

E. Side and adverse effects
   1. Dysrhythmias
   2. Tachycardia
   3. Angina
   4. Restlessness
   5. Urgency or urinary incontinence

F. Interventions
   1. Monitor vital signs.
5. Administer the medication through a large vein.

XVIII. Antilipemic Medications

A. Description
1. Antilipemic medications reduce serum levels of cholesterol, triglycerides, or low-density lipoprotein.
2. When cholesterol, triglyceride, and low-density lipoprotein levels are elevated, the client is at increased risk for coronary artery disease.
3. In many cases, diet alone will not lower blood lipid levels; therefore, antilipemic medications will be prescribed.

B. Bile sequestrants (see Chapter 49)
1. Description
   a. Bind with acids in the intestines, which prevents reabsorption of cholesterol
   b. Should not be used as the only therapy in clients with elevated triglyceride levels because they may raise triglyceride levels
2. Side and adverse effects
   a. Constipation
   b. Gastrointestinal disturbances: Heartburn, nausea, belching, bloating
3. Interventions
   a. Cholestyramine comes in a gritty powder that must be mixed thoroughly in juice or water before administration.
   b. Monitor the client for early signs of peptic ulcer such as nausea and abdominal discomfort followed by abdominal pain and distention.
   c. Instruct the client that the medication must be taken with and followed by sufficient fluids.

C. HMG-CoA reductase inhibitors (Box 53-19)
1. Description
   a. Lovastatin is highly protein-bound and should not be administered with anticoagulants.
   b. Lovastatin should not be administered with gemfibrozil.
   c. Administer lovastatin with caution to the client taking immunosuppressive
medications.

2. Side and adverse effects
   a. Nausea
   b. Diarrhea or constipation
   c. Abdominal pain or cramps
   d. Flatulence
   e. Dizziness
   f. Headache
   g. Blurred vision
   h. Rash
   i. Pruritus
   j. Elevated liver enzyme levels
   k. Muscle cramps and fatigue

3. Interventions
   a. Monitor serum liver enzyme levels.
   b. Instruct the client to have an annual eye examination, because the medications can cause cataract formation.
   c. If lovastatin is not effective in lowering the lipid level after 3 months, it should be discontinued.

   Instruct the client who is taking an antilipemic medication to report any unexplained muscular pain to the PHCP immediately.

D. Other antilipemic medications (Box 53-20)
   1. Description
      a. Gemfibrozil should not be taken with anticoagulants, because they compete for protein sites; if the client is taking an anticoagulant, the anticoagulant dose should be reduced during antilipemic therapy and the INR should be monitored closely.
      b. Do not administer gemfibrozil with HMG-CoA reductase inhibitors, because it increases the risk for myositis, myalgias, and rhabdomyolysis.
      c. Fish oil supplements have been associated with a decreased risk for cardiovascular heart disease; plant stanol and sterol esters and cholestin have been associated with reducing
cholesterol levels.

2. Interventions

a. Monitor vital signs.
b. Monitor liver enzyme levels.
c. Monitor serum cholesterol and triglyceride levels.
d. Instruct the client that it will take several weeks before the lipid level declines.
e. Instruct the client to restrict intake of fats, cholesterol, carbohydrates, and alcohol.
f. Instruct the client to follow an exercise program.
g. Instruct the client to have an annual eye examination and to report changes in vision.
h. Instruct the client with diabetes mellitus who is taking gemfibrozil to monitor blood glucose levels regularly.
i. Instruct the client to increase fluid intake.
j. Nicotinic acid has numerous side and adverse effects, including gastrointestinal disturbances, flushing of the skin, elevated liver enzyme levels, hyperglycemia, and hyperuricemia.
k. Instruct the client that taking aspirin or nonsteroidal antiinflammatory drugs 30 minutes before nicotinic acid may assist in reducing the side effect of cutaneous flushing.
l. Instruct the client to take nicotinic acid with meals to reduce gastrointestinal discomfort.

Box 53-1

Anticoagulants

Oral

- Warfarin sodium
- Dabigatran etexilate mesylate
- Rivaroxaban
- Apixaban

**Parenteral**

- Argatroban
- Bivalirudin
- Dalteparin
- Desirudin
- Enoxaparin
- Fondaparinux
- Heparin sodium

**Box 53-2**

**Substances to Avoid with Anticoagulants**

- Allopurinol
- Cimetidine
- Corticosteroids
- Green, leafy vegetables and other foods high in vitamin K
- Nonsteroidal antiinflammatory drugs
- Oral hypoglycemic agents
- Phenytoin
- Salicylates
- Sulfonamides
- Ginkgo and ginseng (herbs)

**Box 53-3**

**Thrombolytic Medications**

- Alteplase
- Tenecteplase

**Box 53-4**

**Antiplatelet Medications**

Oral
• Acetylsalicylic acid
• Anagrelide
• Cilostazol
• Clopidogrel
• Dipyridamole
• Ticloidine
• Ticagrelor

Parenteral

• Abciximab
• Eptifibatide
• Tirofiban

Box 53-5
Positive Inotropic and Cardiotonic Medications

Dobutamine

• Used for short-term management of heart failure
• Increases myocardial contractility, thereby improving cardiac performance

Dopamine

• Used as a short-term rescue measure for clients with severe, acute heart failure
• Increases myocardial contractility, thereby improving cardiac performance
• Dilates renal blood vessels and increases renal blood flow and urine output

Milrinone Lactate

• Used for short-term management of heart failure; may be given before heart transplantation
FIG. 53-1 The vicious cycle of maladaptive compensatory responses to a failing heart.

Box 53-6
Classifications of Diuretics

- Loop diuretics
- Osmotic diuretics
- Potassium-retaining (sparing) diuretics
- Thiazide diuretics

Box 53-7
Thiazide and Thiazide-Like Diuretics

- Chlorothiazide
- Chlorthalidone
- Hydrochlorothiazide

1796
- Indapamide
- Metolazone

**Box 53-8**

**Loop Diuretics**

- Bumetanide
- Ethacrynic acid
- Furosemide
- Torsemide

**Box 53-9**

**Potassium-Retaining Diuretics**

- Amiloride hydrochloride
- Eplerenone
- Spironolactone
- Triamterene

**Box 53-10**

**Peripherally Acting α-Adrenergic Blockers**

- Doxazosin
- Prazosin
- Terazosin

**Box 53-11**

**Centrally Acting Sympatholytics (Adrenergic Blockers)**

- Clonidine
- Guanfacine
- Methyldopa
### Box 53-12

**Angiotensin-Converting Enzyme Inhibitors and Angiotensin II Receptor Blockers**

**Angiotensin-Converting Enzyme Inhibitors**
- Benazepril
- Captopril
- Fosinopril
- Enalapril
- Lisinopril
- Moexipril
- Perindopril
- Quinapril
- Ramipril
- Trandolapril

**Angiotensin II Receptor Blockers**
- Candesartan
- Eprosartan
- Irbesartan
- Losartan
- Olmesartan
- Telmisartan
- Valsartan

### Box 53-13

**Antianginal Medications (Organic Nitrates)**
- Isosorbide dinitrate
- Isosorbide mononitrate
- Nitroglycerin, sublingual
- Nitroglycerin, translingual
- Nitroglycerin, transdermal patches
- Nitroglycerin ointment
- Intravenous nitroglycerin
### Box 53-14
#### β-Adrenergic Blockers

**Nonselective (Block $\beta_1$ and $\beta_2$)**
- Carvedilol
- Labetalol
- Nadolol
- Pindolol
- Propranolol
- Sotalol

**Cardioselective (Block $\beta_1$)**
- Acebutolol
- Atenolol
- Betaxolol
- Bisoprolol
- Esmolol
- Metoprolol

### Box 53-15
#### Calcium Channel Blockers

- Amlodipine
- Clevidipine
- Diltiazem
- Felodipine
- Isradipine
- Nicardipine
- Nifedipine
- Nimodipine
- Nisoldipine
- Verapamil

### Box 53-16
#### Peripheral Vasodilators

**α-Adrenergic Blockers**
- Doxazosin
- Prazosin
- Terazosin

**Calcium Channel Blockers**

- Diltiazem
- Nifedipine
- Nimodipine
- Verapamil

**Hemorheological**

- Pentoxifylline (increases microcirculation and tissue perfusion)

**Box 53-17**

**Direct-Acting Arteriolar Vasodilators**

- Diazoxide
- Fenoldopam
- Hydralazine
- Nitroglycerin
- Sodium nitroprusside

**Box 53-18**

**Adrenergic Agonists**

- Dobutamine
- Dopamine
- Epinephrine
- Norepinephrine

**Box 53-19**

**HMG-CoA Reductase Inhibitors**

- Atorvastatin
- Fluvastatin
Box 53-20
Other Antilipemic Medications

- Lovastatin
- Pitavastatin
- Pravastatin
- Rosuvastatin
- Simvastatin

Practice Questions

625. A client with atrial fibrillation is receiving a continuous heparin infusion at 1000 units/hr. The nurse determines that the client is receiving the therapeutic effect based on which results?

1. Prothrombin time of 12.5 seconds
2. Activated partial thromboplastin time of 28 seconds
3. Activated partial thromboplastin time of 60 seconds
4. Activated partial thromboplastin time longer than 120 seconds

626. The nurse provides discharge instructions to a client with atrial fibrillation who is taking warfarin sodium. Which statement, by the client, reflects the need for further teaching?

1. “I will avoid alcohol consumption.”
2. “I will take my pills every day at the same time.”
3. “I have already called my family to pick up a MedicAlert bracelet.”
4. “I will take coated aspirin for my headaches because it will coat my stomach.”

627. A client who is receiving digoxin daily has a serum potassium level of 3 mEq/L (3 mmol/L) and reports anorexia. The health care provider prescribes a serum digoxin level to be done. The nurse checks the results and should recognize which level that is outside of the therapeutic range?

1. 0.5 ng/mL (0.63 nmol/L)
2. 0.8 ng/mL (1.02 nmol/L)
3. 0.9 ng/mL (1.14 nmol/L)
4. 2.2 ng/mL (2.8 nmol/L)

628. A client is being treated with procainamide for a cardiac dysrhythmia. Following intravenous administration of the medication, the client complains of dizziness. What intervention should the nurse take first?
   1. Obtain a 12-lead electrocardiogram.
   2. Check the client’s fingerstick blood glucose level.
   3. Auscultate the client’s apical pulse and blood pressure.
   4. Measure the QRS interval duration on the rhythm strip.

629. The nurse is monitoring a client with hypertension who is taking propranolol. Which assessment finding indicates a potential adverse complication associated with this medication?
   1. Report of infrequent insomnia
   2. Development of expiratory wheezes
   3. A baseline blood pressure of 150/80 mm Hg followed by a blood pressure of 138/72 mm Hg after 2 doses of the medication
   4. A baseline resting heart rate of 88 beats per minute followed by a resting heart rate of 72 beats per minute after 2 doses of the medication

630. A client with valvular heart disease who has a clot in the right atrium is receiving a heparin sodium infusion at 1000 units/hr and warfarin sodium 7.5 mg at 5:00 p.m. daily. The morning laboratory results are as follows: activated partial thromboplastin time (aPTT), 32 seconds; international normalized ratio (INR), 1.3. The nurse should take which action based on the client’s laboratory results?
   1. Collaborate with the primary health care provider (PHCP) to discontinue the heparin infusion and administer the warfarin sodium as prescribed.
   2. Collaborate with the PHCP to obtain a prescription to increase the heparin infusion and continue the warfarin sodium as prescribed.
   3. Collaborate with the PHCP to withhold the warfarin sodium since the client is receiving a heparin infusion and the aPTT is within the therapeutic range.
   4. Collaborate with the PHCP to continue the heparin infusion at the same rate and to discuss use of dabigatran etexilate in place of warfarin sodium.

631. A client is diagnosed with an ST segment elevation myocardial infarction (STEMI) and is receiving a tissue plasminogen activator, alteplase. Which action is a priority nursing intervention?
   1. Monitor for kidney failure.
   2. Monitor psychosocial status.
   3. Monitor for signs of bleeding.
   4. Have heparin sodium available.

632. The nurse is monitoring a client for adverse effects of medications. Which findings are characteristic of adverse effects of hydrochlorothiazide? Select all that apply.
   1. Sulfa allergy
2. Osteoporosis
3. Hypokalemia
4. Hypouricemia
5. Hyperglycemia
6. Hypercalcemia

633. The home health care nurse is visiting a client with coronary artery disease with elevated triglyceride levels and a serum cholesterol level of 398 mg/dL (10 mmol/L). The client is taking cholestyramine, and the nurse teaches the client about the medication. Which statement by the client indicates the need for further teaching?

1. “Constipation and bloating might be a problem.”
2. “I’ll continue to watch my diet and reduce my fats.”
3. “Walking a mile each day will help the whole process.”
4. “I’ll continue my nicotinic acid from the health food store.”

634. The nurse is monitoring a client with heart failure who is taking digoxin. Which findings are characteristic of digoxin toxicity? Select all that apply.

1. Tremors
2. Diarrhea
3. Irritability
4. Blurred vision
5. Nausea and vomiting

635. Prior to administering a client’s daily dose of digoxin to treat heart failure, the nurse reviews the client’s laboratory data and notes the following results: serum calcium, 9.8 mg/dL (2.45 mmol/L); serum magnesium, 1.0 mEq/L (0.4 mmol/L); serum potassium, 4.1 mEq/L (4.1 mmol/L); serum creatinine, 0.9 mg/dL (79.5 mcmol/L). Which result should alert the nurse that the client is at risk for digoxin toxicity?

1. Serum calcium level
2. Serum potassium level
3. Serum creatinine level
4. Serum magnesium level

636. The nurse administered intravenous bumetanide to a client being treated for heart failure. Which outcome indicates that the medication has achieved the expected effect?

1. Cough becomes productive of frothy pink sputum.
2. Urine output increases from 10 mL/hr to greater than 50 mL hourly.
3. The serum potassium level changes from 3.8 to 3.1 mEq/L (3.8 to 3.1 mmol/L).
4. B-type natriuretic peptide (BNP) factor increases from 200 to 262 ng/mL (200 to 262 mcg/L).

637. Intravenous heparin therapy is prescribed for a client with atrial fibrillation.
While implementing this prescription, the nurse ensures that which medication is available on the nursing unit?

1. Vitamin K
2. Protamine sulfate
3. Potassium chloride
4. Aminocaproic acid

638. A client receiving thrombolytic therapy with a continuous infusion of alteplase suddenly becomes extremely anxious and reports itching. The nurse hears stridor and notes generalized urticaria and hypotension. Which interventions should the nurse anticipate? Select all that apply.

☐ 1. Stop the infusion.
☐ 2. Raise the head of the bed.
☐ 4. Administer diphenhydramine.
☐ 5. Call for the Rapid Response Team (RRT).

639. The nurse should report which assessment finding to the primary health care provider (PHCP) before initiating thrombolytic therapy in a client with pulmonary embolism?

1. Adventitious breath sounds
2. Temperature of 99.4°F (37.4°C) orally
3. Blood pressure of 198/110 mm Hg
4. Respiratory rate of 28 breaths per minute

640. The nurse provides instructions to the client about nicotinic acid prescribed for hyperlipidemia. Which statement by the client indicates understanding of the instructions?

1. “The medication should be taken with meals to decrease flushing.”
2. “It is not necessary to avoid the use of alcohol when taking nicotinic acid.”
3. “Clay-colored stools are a common side effect and should not be of concern.”
4. “Ibuprofen taken 30 minutes before the nicotinic acid may decrease the flushing.”

**Answers**

625. Answer: 3

**Rationale:** Common laboratory ranges for activated partial thromboplastin time (aPTT) are 30 to 40 seconds. Because the aPTT should be 1.5 to 2.5 times the normal value, the client’s aPTT would be considered therapeutic if it was 60 seconds. Prothrombin time assesses response to warfarin therapy.

**Test-Taking Strategy:** Focus on the subject, the therapeutic effect of heparin. Prothrombin time is eliminated because it assesses response to warfarin therapy. The
aPTT of 28 seconds is eliminated because this result indicates that the client is receiving no therapeutic effect from the continuous heparin infusion. Finally, the aPTT greater than 120 seconds can be eliminated because this value is beyond the therapeutic range and the client is at risk for bleeding.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Pharmacology: Cardiovascular Medications: Anticoagulants  
**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias  
**Priority Concepts:** Clotting; Safety  

**Answer:** 4

**Rationale:** Aspirin-containing products need to be avoided when a client is taking this medication. Alcohol consumption should be avoided by a client taking warfarin sodium. Taking the prescribed medication at the same time each day increases client compliance. The MedicAlert bracelet provides health care personnel with emergency information.

**Test-Taking Strategy:** Note the **strategic words**, need for further teaching. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Recalling that warfarin is an anticoagulant and that coated aspirin is an aspirin-containing product will direct you to the correct option.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Pharmacology: Cardiovascular Medications: Anticoagulants  
**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias  
**Priority Concepts:** Client Education; Safety  

**Answer:** 4

**Rationale:** The optimal therapeutic range for digoxin is 0.5 to 2.0 ng/mL (0.63 to 2.56 nmol/L). If the client is experiencing symptoms such as anorexia and is experiencing hypokalemia as evidenced by a low potassium level, digoxin toxicity is a concern. Therefore, option 4 is correct because it is outside of the therapeutic level and elevated.

**Test-Taking Strategy:** Focus on the **subject**, a digoxin level outside of the therapeutic range. Additionally, **determine if an abnormality exists.** Note that the client is experiencing anorexia and has a low serum potassium level. Therefore, it is best to select the option that identifies the highest level. Recall that in hypokalemia, the client is at greater risk for digoxin toxicity.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment
628. **Answer:** 3

**Rationale:** Signs of toxicity from procainamide include confusion, dizziness, drowsiness, decreased urination, nausea, vomiting, and tachydysrhythmias. If the client complains of dizziness, the nurse should assess the vital signs first. Although measuring the QRS duration on the rhythm strip and obtaining a 12-lead electrocardiogram may be interventions, these would be done after the vital signs are taken. Dizziness directly following the procainamide indicates that the medication was the likely cause and should be addressed before assessing for other possible causes such as hypoglycemia.

**Test-Taking Strategy:** Note the strategic word, first. Also use the steps of the nursing process to answer correctly. Remember to always assess the client first, not the monitoring devices. Therefore, auscultating the apical pulse and taking the blood pressure are the first actions.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Pharmacology: Cardiovascular Medications: Antidysrhythmics

**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias

**Priority Concepts:** Clinical Judgment; Perfusion

629. **Answer:** 2

**Rationale:** Audible expiratory wheezes may indicate a serious adverse reaction, bronchospasm. Beta blockers may induce this reaction, particularly in clients with chronic obstructive pulmonary disease or asthma. Normal decreases in blood pressure and heart rate are expected. Insomnia is a frequent mild side effect and should be monitored.

**Test-Taking Strategy:** Focus on the subject, a potential adverse complication. Eliminate options indicating a decrease in blood pressure and a decrease in heart rate first, because these are expected effects from the medication. Next, focusing on the subject will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Pharmacology: Cardiovascular Medications: Beta blockers

**Health Problem:** Adult Health: Cardiovascular: Hypertension

**Priority Concepts:** Gas Exchange; Perfusion

630. **Answer:** 2

1806
**Rationale:** When a client is receiving warfarin for clot prevention due to atrial fibrillation, an INR of 2 to 3 is appropriate for most clients. Until the INR has achieved a therapeutic range, the client should be maintained on a continuous heparin infusion with the aPTT ranging between 60 and 80 seconds. Therefore, the nurse should collaborate with the HCP to obtain a prescription to increase the heparin infusion and to administer the warfarin as prescribed.

**Test-Taking Strategy:** Focus on the **subject**, laboratory result analysis related to these medications. First, eliminate the option that indicates to discuss use of dabigatran etexilate, recalling that it is contraindicated for use in atrial fibrillation associated with valvular heart disease. Next, recall that if the warfarin sodium has achieved the therapeutic range for the INR for clot prevention in atrial fibrillation, the heparin infusion is no longer necessary. This will help you eliminate the option that indicates to withhold the warfarin sodium because the INR is not therapeutic. Last, keep in mind that if both the aPTT and the INR are not within therapeutic range, the client is left unprotected from clot formation.

**Level of Cognitive Ability:** Synthesizing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Pharmacology: Cardiovascular Medications: Anticoagulants

**Health Problem:** Adult Health: Cardiovascular: Dysrhythmias

**Priority Concepts:** Clotting; Collaboration

631. **Answer:** 3

**Rationale:** Tissue plasminogen activator is a thrombolytic. Hemorrhage is a complication of any type of thrombolytic medication. The client is monitored for bleeding. Monitoring for renal failure and monitoring the client’s psychosocial status are important but are not the most critical interventions. Heparin may be administered after thrombolytic therapy, but the question is not asking about follow-up medications.

**Test-Taking Strategy:** Note the **strategic word**, priority. Remember that bleeding is a priority for thrombolytic medications.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Pharmacology: Cardiovascular Medications: Thrombolytics

**Health Problem:** Adult Health: Cardiovascular: Myocardial infarction

**Priority Concepts:** Clotting; Safety

632. **Answer:** 1, 3, 5, 6

**Rationale:** Thiazide diuretics such as hydrochlorothiazide are sulfa-based medications, and a client with a sulfa allergy is at risk for an allergic reaction. Also, clients are at risk for hypokalemia, hyperglycemia, hypercalcemia, hyperlipidemia, and hyperuricemia.
**Test-Taking Strategy:** Focus on the **subject**, a concern related to administration of hydrochlorothiazide. Recall that thiazide diuretics chemical make-up carry a sulfa ring.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Cardiovascular Medications: Diuretics  
**Health Problem:** Adult Health: Cardiovascular: Hypertension  
**Priority Concepts:** Clinical Judgment; Safety  

633. **Answer:** 4

**Rationale:** Nicotinic acid, even an over-the-counter form, should be avoided because it may lead to liver abnormalities. All lipid-lowering medications also can cause liver abnormalities, so a combination of nicotinic acid and cholestyramine resin needs to be avoided. Constipation and bloating are the 2 most common adverse effects. Walking and the reduction of fats in the diet are therapeutic measures to reduce cholesterol and triglyceride levels.

**Test-Taking Strategy:** Note the **strategic words**, need for further teaching. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Remembering that over-the-counter medications should be avoided when a client is taking a prescription medication will direct you to the correct option.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Pharmacology: Cardiovascular Medications: Antilipemics  
**Health Problem:** Adult Health: Cardiovascular: Coronary Artery Disease  
**Priority Concepts:** Client Education; Safety  

634. **Answer:** 2, 4, 5

**Rationale:** Digoxin is a cardiac glycoside. The risk of toxicity can occur with the use of this medication. Toxicity can lead to life-threatening events and the nurse needs to monitor the client closely for signs of toxicity. Early signs of toxicity include gastrointestinal manifestations such as anorexia, nausea, vomiting, and diarrhea. Subsequent manifestations include headache; visual disturbances such as diplopia, blurred vision, yellow-green halos, and photophobia; drowsiness; fatigue; and weakness. Cardiac rhythm abnormalities can also occur. The nurse also monitors the digoxin level. The optimal therapeutic range for digoxin is 0.5 to 2.0 ng/mL (0.63 to 2.56 nmol/L).

**Test-Taking Strategy:** Focus on the **subject**, digoxin toxicity. Specific knowledge regarding the characteristics of digoxin toxicity is needed to answer this question. Recall that the early signs are gastrointestinal manifestations. Next, recall that visual
disturbances can occur.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Cardiovascular Medications: Cardiac Glycosides  
**Health Problem:** Adult Health: Cardiovascular: Heart Failure  
**Priority Concepts:** Clinical Judgment; Safety  

635. **Answer:** 4

**Rationale:** An increased risk of toxicity exists in clients with hypercalcemia, hypokalemia, hypomagnesemia, hypothyroidism, and impaired renal function. The calcium, creatinine, and potassium levels are all within normal limits. The normal range for magnesium is 1.8–2.6 mEq/L (0.74–1.07 mmol/L), and the results in the correct option are reflective of hypomagnesemia.

**Test-Taking Strategy:** Focus on the subject, the laboratory result that places the client at risk for digoxin toxicity. Recalling the normal laboratory values for each electrolyte identified in the options will assist in answering correctly.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Cardiovascular Medications: Cardiac Glycosides  
**Health Problem:** Adult Health: Cardiovascular: Heart Failure  
**Priority Concepts:** Perfusion; Safety  

636. **Answer:** 2

**Rationale:** Bumetanide is a diuretic and expected outcomes include increased urine output, decreased crackles, and decreased weight. Potassium loss is a side effect rather than an expected effect of the diuretic. Frothy pink sputum indicates progression to pulmonary edema. A BNP greater than 100 pg/mL (100 ng/L) is indicative of heart failure; thus, a rise from a previous level indicates worsening of the condition.

**Test-Taking Strategy:** Focus on the subject, assessment findings indicative of the expected effect of bumetanide. Keep in mind when answering this question that an expected effect of a medication refers to a positive outcome versus a side or adverse effect. This will help you eliminate the option that refers to the potassium loss.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Pharmacology: Cardiovascular Medications: Diuretics  
**Health Problem:** Adult Health: Cardiovascular: Heart Failure  
**Priority Concepts:** Evidence; Perfusion  
Rationale: The antidote to heparin is protamine sulfate; it should be readily available for use if excessive bleeding or hemorrhage should occur. Vitamin K is an antidote for warfarin sodium. Potassium chloride is administered for a potassium deficit. Aminocaproic acid is the antidote for thrombolytic therapy.

Test-Taking Strategy: Focus on the subject, the antidote for heparin. Knowledge regarding the various antidotes is needed to answer this question. Remember that the antidote to heparin is protamine sulfate.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Planning
Content Area: Pharmacology: Cardiovascular Medications: Anticoagulants
Health Problem: Adult Health: Cardiovascular: Dysrhythmias
Priority Concepts: Clotting; Safety

Rationale: The client is experiencing an anaphylactic reaction. Therefore, the priority action is to stop the infusion and notify the RRT. The client may be treated with antihistamines. Raising the head of the bed would not be helpful, as that may exacerbate the hypotension. Protamine sulfate is the antidote for heparin, so it is not useful for a client receiving alteplase.

Test-Taking Strategy: Note the strategic word, priority. Recall that an allergic reaction and possible anaphylaxis are risks associated with alteplase therapy. Also, focusing on the signs and symptoms in the question will assist in answering correctly. When a severe allergic reaction occurs, the offending substance should be stopped, and lifesaving treatment should begin.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Complex Care: Shock
Health Problem: Adult Health: Cardiovascular: Shock
Priority Concepts: Clinical Judgment; Gas Exchange

Rationale: Thrombolytic therapy is contraindicated in severe uncontrolled hypertension because of the risk of cerebral hemorrhage. Therefore, the nurse would report the results of the blood pressure to the PHCP before initiating therapy.

Test-Taking Strategy: Focus on the subject, a contraindication for the use of thrombolytic therapy. Adventitious breath sounds, temperature of 99.4°F (37.4°C), and respiratory rate of 28 breaths per minute may be present in the client with pulmonary embolism but are not necessarily signs that warrant reporting before thrombolytic therapy is initiated.
Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Pharmacology: Cardiovascular: Thrombolytics
Health Problem: Adult Health: Respiratory: Pulmonary Embolism
Priority Concepts: Clinical Judgment; Clotting

640. Answer: 4

Rationale: Flushing is an adverse effect of this medication. Aspirin or a nonsteroidal antiinflammatory drug, as prescribed, can be taken 30 minutes prior to taking the medication to decrease flushing. Alcohol consumption needs to be avoided because it will enhance this effect. The medication should be taken with meals to decrease gastrointestinal upset; however, taking the medication with meals has no effect on the flushing. Clay-colored stools are a sign of hepatic dysfunction and should be reported to the primary health care provider (PHCP) immediately.

Test-Taking Strategy: Focus on the subject, client understanding of the medication. Alcohol must be abstained from, so this option can be eliminated. Taking the medication with meals helps decrease the gastrointestinal symptoms rather than flushing. Clay-colored stools are a sign of hepatic dysfunction and should be reported to the PHCP immediately.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Pharmacology: Cardiovascular Medications: Antilipemics
Health Problem: Adult Health: Cardiovascular: Coronary Artery Disease
Priority Concepts: Client Education; Safety
UNIT XIII
Renal and Urinary Problems of the Adult Client
Introduction

Pyramid to Success

Pyramid Points focus on acute kidney injury and chronic kidney disease, dialysis procedures, urinary diversions, and postoperative care following urinary or renal surgery. Be familiar with medical conditions and diagnostic tests that place the client at risk for acute kidney injury. Focus on the major problems associated with kidney failure and the rationale for the prescribed treatment modalities. Be familiar with the complications associated with hemodialysis and peritoneal dialysis, the specific assessment data related to complications, and the expected treatment. Focus on the care of a peritoneal catheter and hemodialysis access devices, the complications associated with these access devices, and the appropriate nursing interventions if a complication is suspected. Review assessment data indicating rejection following kidney transplantation. Be familiar with care for the client following prostatectomy and treatment measures for the client with urinary or renal calculi.

Client Needs: Learning Objectives

Safe and Effective Care Environment

Consulting with the interprofessional health care team
Establishing priorities
Identifying conditions and diagnostic procedures that increase the risk of developing renal problems
Identifying the guidelines related to kidney organ donation
Maintaining asepsis related to wound care and dialysis access devices
Maintaining confidentiality related to the renal disorder
Maintaining standard and other precautions related to care for the client
Preventing injury related to complications of the disorder
Upholding client rights
Verifying that informed consent related to diagnostic and surgical procedures has been obtained

Health Promotion and Maintenance

Performing urinary and renal physical assessment techniques
Providing client instructions regarding prescribed treatments related to the urinary or renal disorder
Providing client instructions regarding the prevention of the recurrence of a urinary or renal problem

**Psychosocial Integrity**

- Assisting the client to use appropriate coping mechanisms
- Discussing body image disturbances
- Discussing the loss of renal function
- Identifying cultural, religious, and spiritual influences on health
- Identifying grief and loss and end-of-life issues
- Identifying support systems and appropriate community resources

**Physiological Integrity**

- Ensuring elimination measures
- Informing the client about diagnostic tests and laboratory results
- Monitoring for fluid and electrolyte imbalances and acid-base disorders
- Obtaining assessment data indicating rejection of kidney transplant
- Preventing complications arising as a result of dialysis
- Providing adequate rest and sleep
- Providing care related to hemodialysis and peritoneal dialysis and dialysis access devices
- Providing care to the client following prostatectomy
- Providing comfort interventions
- Providing pharmacological therapy
- Providing treatment measures for the client with renal or urinary calculi
- Teaching the client about the prescribed nutrition and fluid measures
I. Anatomy and Physiology
   A. Kidney anatomy
      1. Each person has 2 kidneys, which are located behind the peritoneum; attached at the level of the last thoracic and first 3 lumbar vertebrae, on the right and left sides.
      2. The kidneys are enclosed in the renal capsule.
      3. The renal cortex is the outer layer of the renal capsule, which contains blood-filtering mechanisms (glomeruli).
      4. The renal medulla is the inner region, which contains the renal pyramids and renal tubules.
      5. Together, the renal cortex, pyramids, and medulla constitute the parenchyma.
      6. Nephrons
         a. Located within the parenchyma
         b. Composed of glomerulus and tubules
         c. Selectively secretes and reabsorbs ions and filtrates, including fluid, wastes, electrolytes, acids, and bases

   7. Glomerulus
      a. Each nephron contains tufts of capillaries, which filter large plasma proteins and blood cells.
      b. Blood flows into the glomerular capillaries from the afferent arteriole and flows out of the glomerular capillaries into the efferent arteriole.

   8. Bowman’s capsule
a. Thin double-walled capsule that surrounds the glomerulus
b. Fluid and particles from the blood such as electrolytes, glucose, amino acids, and metabolic waste (glomerular filtrate) are filtered through the glomerular membrane into a fluid-filled space in Bowman’s capsule (Bowman’s space) and then enter the proximal convoluted tubule (PCT).

9. Tubules

a. The tubules include the PCT, the loop of Henle, and the distal convoluted tubule (DCT).
b. The PCT receives filtrate from the glomerular capsule and reabsorbs water and electrolytes through active and passive transport.
c. The descending loop of Henle passively reabsorbs water from the filtrate.
d. The ascending loop of Henle passively reabsorbs sodium and chloride from the filtrate and helps maintain osmolality.
e. The DCT actively and passively removes sodium and water.
f. The filtered fluid is converted to urine in the tubules, and then the urine moves to the pelvis of the kidney.
g. The urine flows from the pelvis of the kidneys through the ureters and empties into the bladder.

B. Functions of kidneys

1. Maintain acid–base balance
2. Excrete end products of body metabolism
3. Control fluid and electrolyte balance
4. Excrete bacterial toxins, water-soluble medications, and medication metabolites
5. Secrete renin to regulate the blood pressure (BP) and erythropoietin to stimulate the bone marrow to produce red blood cells
6. Synthesize vitamin D for calcium absorption and regulation of the parathyroid hormones

C. Urine production

1. As fluid flows through the tubules, water, electrolytes, and solutes are reabsorbed, and other solutes such as creatinine, hydrogen ions, and potassium are
secreted.
2. Water and solutes that are not reabsorbed become urine.
3. The process of selective reabsorption determines the amount of water and solutes to be secreted.

D. Homeostasis of water

1. Antidiuretic hormone (ADH) is primarily responsible for the reabsorption of water by the kidneys.
2. ADH is produced by the hypothalamus and secreted from the posterior lobe of the pituitary gland.
3. Secretion of ADH is stimulated by dehydration or high sodium intake and by a decrease in blood volume.
4. ADH makes the distal convoluted tubules and collecting duct permeable to water.
5. Water is drawn out of the tubules by osmosis and returns to the blood; concentrated urine remains in the tubule to be excreted.
6. When ADH is lacking, the client develops diabetes insipidus (DI).
7. Clients with DI produce large amounts of dilute urine; treatment is necessary because the client cannot drink sufficient water to survive.

E. Homeostasis of sodium

1. When the amount of sodium increases, extra water is retained to preserve osmotic pressure.
2. An increase in sodium and water produces an increase in blood volume and BP.
3. When the BP increases, glomerular filtration increases, and extra water and sodium are lost; blood volume is reduced, returning the BP to normal.
4. Reabsorption of sodium in the distal convoluted tubules is controlled by the renin-angiotensin system.
5. Renin, an enzyme, is released from the nephron when the BP or fluid concentration in the distal convoluted tubule is low.
6. Renin catalyzes the splitting of angiotensin I from angiotensinogen; angiotensin I converts to angiotensin II as blood flows through the lung.
7. Angiotensin II, a potent vasoconstrictor, stimulates the secretion of aldosterone.
8. Aldosterone stimulates the distal convoluted tubules to reabsorb sodium and secrete potassium.
9. The additional sodium increases water reabsorption and increases blood volume and BP, returning the BP
to normal; the stimulus for the secretion of renin then is removed.

F. Homeostasis of potassium

1. Increases in the serum potassium level stimulate the secretion of aldosterone.
2. Aldosterone stimulates the distal convoluted tubules to secrete potassium; this action returns the serum potassium concentration to normal.

G. Homeostasis of acidity (pH)

1. Blood pH is controlled by maintaining the concentration of buffer systems.
2. Carbonic acid and sodium bicarbonate form the most important buffers for neutralizing acids in the plasma.
3. The concentration of carbonic acid is controlled by the respiratory system.
4. The concentration of sodium bicarbonate is controlled by the kidneys.
5. Normal arterial pH is 7.35 to 7.45, maintained by keeping the ratio of concentrations of sodium bicarbonate to carbon dioxide constant at 20:1.
6. Strong acids are neutralized by sodium bicarbonate to produce carbonic acid and the sodium salts of the strong acid; this process quickly restores the ratio and thus blood pH.
7. The carbonic acid dissociates into carbon dioxide and water; because the concentration of carbon dioxide is maintained at a constant level by the respiratory system, the excess carbonic acid is rapidly excreted.
8. Sodium combined with the strong acid is actively reabsorbed in the distal convoluted tubules in exchange for hydrogen or potassium ions. The strong acid is neutralized by ammonia and is excreted as ammonia or potassium salts.

H. Adrenal glands (see Chapter 46 for information about the adrenal glands)

1. One adrenal gland is on top of each kidney.
2. The adrenal glands influence BP and sodium and water retention.

I. Bladder

1. The bladder detrusor muscle, composed of smooth muscle, distends during bladder filling and contracts during bladder emptying.
2. The ureterovesical sphincter prevents reflux of urine from the bladder to the ureter.
3. The total bladder capacity is 1 L; normal adult urine output is 1500 mL/day.

J. Prostate gland
1. The prostate gland surrounds the male urethra.
2. The prostate gland contains a duct that opens into the prostatic portion of the urethra and secretes the alkaline portion of seminal fluid, which protects sperm.

K. Risk factors associated with renal disorders (Box 54-1)

II. Diagnostic Tests
A. See Chapter 10 and Box 54-2 for information regarding normal values for renal function studies.
B. Determination of serum creatinine level
   1. Description: A test that measures the amount of creatinine in the serum. Creatinine is an end product of protein and muscle metabolism.
   2. Analysis
      a. Creatinine level reflects the glomerular filtration rate.
      b. Kidney disease is the only pathological condition that increases the serum creatinine level.
      c. Serum creatinine level increases only when at least 50% of renal function is lost.
C. Determination of blood urea nitrogen (BUN) level
   1. Description: A serum test that measures the amount of nitrogenous urea, a byproduct of protein metabolism in the liver.
   2. Analysis
      a. BUN levels indicate the extent of renal clearance of urea nitrogenous waste products.
      b. An elevation does not always mean that renal disease is present.
      c. Some factors that can elevate the BUN level include dehydration, poor renal perfusion, intake of a high-protein diet, infection, stress, corticosteroid use, gastrointestinal (GI) bleeding, and factors that cause muscle breakdown.
D. BUN/creatinine ratio
   1. The BUN level is divided by the creatinine level to obtain the ratio.
   2. When the BUN and serum creatinine levels increase at the same rate, the ratio of BUN to creatinine remains constant.
   3. Elevated serum creatinine and BUN levels suggest renal dysfunction.
   4. A decreased BUN/creatinine ratio occurs with fluid volume deficit, obstructive uropathy, catabolic state,
and a high-protein diet.
5. An increased BUN/creatinine ratio occurs with fluid volume excess.

E. Urinalysis
1. Description: A urine test for evaluation of the renal system and renal disease (Table 54-1)
2. Interventions
   a. Wash perineal area and use a clean container for collection.
   b. Obtain 10 to 15 mL of the first morning voiding if possible.
   c. Refrigerating samples may alter the specific gravity.
   d. If the client is menstruating, note this on the laboratory requisition form.

F. A 24-hour urine collection
1. Check with the laboratory about specific instructions for the client to follow, such as dietary or medication restrictions.
2. Instruct the client about the urine collection.
3. At the start time, instruct the client to void and discard that sample.
4. Collect all urine for the prescribed time (24 hours).
5. Keep the urine specimen on ice or refrigerated and check with the laboratory regarding adding a preservative to the specimen during collection.
6. At the end of the prescribed time, instruct the client to empty the bladder and add that urine to the collection container.

G. Specific gravity determination
1. Description: A urine test that measures the ability of the kidneys to concentrate urine
2. Interventions
   a. Specific gravity can be measured by a multiple-test dipstick method (most common method), refractometer (an instrument used in the laboratory setting), or urinometer (least accurate method).
   b. Factors that interfere with an accurate reading include radiopaque contrast agents, glucose, and proteins.
   c. Cold specimens may produce a false high reading.
   d. Normal random reference interval is 1.003 to 1.030 (may vary depending on the laboratory).
   e. An increase in specific gravity (more
concentrated urine) occurs with insufficient fluid intake, decreased renal perfusion, or increased ADH.
f. A decrease in specific gravity (less concentrated urine) occurs with increased fluid intake or diabetes insipidus; it may also indicate renal disease or the kidneys’ inability to concentrate urine.

H. Urine culture and sensitivity testing
1. Description: A urine test that identifies the presence of microorganisms (culture) and determines the specific antibiotics to treat the existing microorganism (sensitivity) appropriately
2. Interventions
   a. Clean the perineal area and urinary meatus with a bacteriostatic solution.
   b. Collect the midstream sample in a sterile container (clean catch specimen); if the client is unable to obtain a clean catch specimen, a specimen obtained by straight catheterization may be prescribed.
   c. Send the collected specimen to the laboratory immediately.
   d. Identify any sources of potential contaminants during the collection of the specimen, such as the hands, skin, clothing, hair, or vaginal or rectal secretions; if contamination occurs, the specimen is discarded and a new specimen needs to be collected. Urine from the client who drank a very large amount of fluids may be too dilute to provide a positive culture.

I. Creatinine clearance test
1. Description
   a. The creatinine clearance test evaluates how well the kidneys remove creatinine from the blood, and is an estimate of glomerular filtration rate (GFR).
   b. The test includes obtaining a blood sample and timed urine specimens.
   c. Blood is drawn when the urine specimen collection is complete.
   d. The urine specimen for the creatinine
clearance is usually collected for 24 hours, but shorter periods such as 8 or 12 hours could be prescribed.

The creatinine clearance test provides the best estimate of the GFR; the normal GFR is 125 mL per minute in a young adult. The GFR decreases with age (10% for each decade). By age 65 years the GFR approximately 65 mL per minute.

2. Interventions
   a. Encourage fluids before and during the test.
   b. Instruct the client to avoid caffeinated beverages during testing.
   c. Check with the primary health care provider (PHCP) regarding the administration of any prescribed medications during testing.
   d. Instruct the client about the urine collection.
   e. At the start time, ask the client to void (or empty the tubing and drainage bag if the client has a urinary catheter) and discard the first sample.
   f. Collect all urine for the prescribed time.
   g. Keep the urine specimen on ice or refrigerated and check with the laboratory regarding adding a preservative to the specimen during collection.
   h. At the end of the prescribed time, ask the client to empty the bladder (or empty the tubing and drainage bag if the client has a urinary catheter) and add that final urine to the collection container.
   i. Send the labeled urine specimen to the laboratory.
   j. Document specimen collection, time started and completed, and pertinent assessments.

J. KUB (kidneys, ureters, and bladder) radiography
   1. Description: An x-ray of the urinary system and adjacent structures to detect urinary calculi.
   2. Interventions: No specific preparation is necessary.

K. Bladder ultrasonography (bladder scanning)
   1. Bladder ultrasonography is a noninvasive method for
measuring the volume of urine in the bladder.

2. Bladder ultrasonography may be performed to evaluate urinary frequency, inability to urinate, or amount of residual urine (the amount of urine remaining in the bladder after voiding).

L. Intravenous urography

1. Description: An x-ray procedure in which an intravenous (IV) injection of a radiopaque dye is used to visualize and identify abnormalities in the renal system.

2. Preprocedure interventions
   a. Verify that an informed consent was obtained.
   b. Assess the client for allergies to iodine, seafood, and radiopaque dyes and contraindications for the test, including a positive pregnancy test; cautions include medical history of asthma, significant cardiac disease, and renal insufficiency.
   c. Withhold food and fluids for the time prescribed.
   d. Administer laxatives if prescribed.
   e. Inform the client about possible throat irritation, flushing of the face, warmth, or a salty or metallic taste during the test.

3. Postprocedure interventions
   a. Monitor vital signs.
   b. Instruct the client to drink at least 1 L of fluid unless contraindicated.
   c. Monitor urinary output.
   d. Monitor for signs of a possible allergic reaction to the dye used during the test and instruct the client to notify the PHCP if any signs of an allergic reaction occur.
   e. Contrast dye is potentially damaging to kidneys; the risk is greater in older clients and those experiencing dehydration.
M. Renography (kidney scan)

1. Description: An IV injection of a radioisotope for visual imaging of renal blood flow, glomerular filtration, tubular function, and excretion

2. Preprocedure interventions
   a. Verify that an informed consent was obtained.
   b. Assess for allergies.
   c. Inform the client that the test requires no dietary or activity restrictions.
   d. Instruct the client to remain motionless during the test and that imaging may be repeated at various intervals before the test is complete.

3. Postprocedure interventions
   a. Encourage fluid intake unless contraindicated.
   b. Assess the client for signs of an allergic reaction.
   c. The radioisotope is eliminated in 24 hours; wear gloves for excretion precautions.
   d. Follow standard precautions when caring for incontinent clients and double-bag client linens per agency policy.
   e. If captopril was administered during the procedure, the client’s BP should be checked frequently.

N. Cystoscopy and biopsy of the bladder

1. Description: The bladder mucosa is examined for inflammation, calculi, or tumors by means of a cystoscope; a sample for biopsy may be obtained.

2. Preprocedure interventions
   a. Verify that an informed consent was obtained.
   b. If a biopsy is planned, withhold food
and fluids for the time prescribed.
c. If a cystoscopy alone is planned, no special preparation is necessary, and the procedure may be performed in the PHCP’s office; postprocedure interventions include increasing fluid intake.

3. Postprocedure interventions following biopsy

a. Monitor vital signs.
b. Increase fluid intake as prescribed.
c. Monitor intake and output and assess urine characteristics.
d. Encourage deep-breathing exercises to relieve bladder spasms and administer analgesics as prescribed.
e. Administer sitz or tub baths for back and abdominal pain if prescribed.
f. Note that leg cramps are common because of the lithotomy position maintained during the procedure.
g. Inform the client that burning on urination, pink-tinged or tea-colored urine, and urinary frequency are common after cystoscopy and resolve in a few days.
h. Monitor for bright red urine or clots, and notify the PHCP if a fever occurs; an increase in white blood cell (WBC) count suggests infection.

O. Renal biopsy

1. Description: Insertion of a needle into the kidney to obtain a sample of tissue for examination; usually done percutaneously

2. Preprocedure interventions

a. Assess vital signs.
b. Assess baseline coagulation studies; notify the PHCP if abnormal results are noted.
c. Verify that an informed consent was obtained.
d. Withhold food and fluids as prescribed.

3. Intervention during the procedure: Position the client prone with a pillow under the abdomen and shoulders.

4. Postprocedure interventions
a. Monitor vital signs, especially for hypotension and tachycardia, which could indicate bleeding.

b. Provide pressure to the biopsy site for 30 minutes or as prescribed.

c. Monitor the hemoglobin and hematocrit levels for decreases, which could indicate bleeding.

d. Place the client on strict bed rest in the supine position with a back roll for additional support for 2 to 6 hours after the biopsy.

e. Check the biopsy site and under the client for bleeding.

f. Encourage fluid intake of 1500 to 2000 mL as prescribed.

g. Observe the urine for gross and microscopic bleeding.

h. Instruct the client to avoid heavy lifting and strenuous activity for 1 to 2 weeks.

i. Instruct the client to notify the PHCP if either a temperature greater than 100° F (37.8° C) or hematuria occurs after the first 24 hours postprocedure.

III. Acute Kidney Injury

A. Description

1. **Acute kidney injury (AKI)** is the rapid loss of kidney function from renal cell damage.
2. Occurs abruptly and can be reversible
3. AKI leads to cell hypoperfusion, cell death, and decompensation of renal function.
4. The prognosis depends on the cause and the condition of the client.
5. Near-normal or normal kidney function may resume gradually.

B. Causes

1. Prerenal: Outside the kidney; caused by intravascular volume depletion such as with blood loss associated with trauma or surgery, dehydration, decreased cardiac output (as with cardiogenic shock), decreased peripheral vascular resistance, decreased
renovascular blood flow, and prerenal infection or obstruction.

2. Intrarenal: Within the parenchyma of the kidney; caused by tubular necrosis, prolonged prerenal ischemia, intrarenal infection or obstruction, and nephrotoxicity (Box 54-3)

3. Postrenal: Between the kidney and urethral meatus, such as bladder neck obstruction, bladder cancer, calculi, and postrenal infection

C. Phases of AKI and interventions (Box 54-4)

1. Onset: Begins with precipitating event
2. Oliguric phase
   a. For some clients, oliguria does not occur and the urine output is normal; otherwise, the duration of oliguria is 8 to 15 days; the longer the duration, the less chance of recovery.
   b. Sudden decrease in urine output; urine output is less than 400 mL/day.
   c. Signs of excess fluid volume:
      Hypertension, edema, pleural and pericardial effusions, dysrhythmias, heart failure, and pulmonary edema
   d. Signs of uremia: Anorexia, nausea, vomiting, and pruritus
   e. Signs of metabolic acidosis: Kussmaul’s respirations
   f. Signs of neurological changes: Tingling of extremities, drowsiness progressing to disorientation, and then coma
   g. Signs of pericarditis: Friction rub, chest pain with inspiration, and low-grade fever
   h. Laboratory analysis (see Box 54-4)
   i. With early recognition or potential for AKI, client may be treated with fluid challenges (IV boluses of 500 to 1000 mL over 1 hour).
   j. Restrict fluid intake; if hypertension is present, daily fluid allowances may be 400 to 1000 mL plus the measured urinary output.
   k. Administer medications, such as
diuretics, as prescribed to increase renal blood flow and diuresis of retained fluid and electrolytes.

3. Diuretic phase
   a. Urine output rises slowly, followed by diuresis (4 to 5 L/day).
   b. Excessive urine output indicates that damaged nephrons are recovering their ability to excrete wastes.
   c. Dehydration, hypovolemia, hypotension, and tachycardia can occur.
   d. Level of consciousness improves.
   e. Laboratory analysis (see Box 54-4)
   f. Administer IV fluids as prescribed, which may contain electrolytes to replace losses.

4. Recovery phase (convalescent)
   a. Recovery is a slow process; complete recovery may take 1 to 2 years.
   b. Urine volume returns to normal.
   c. Memory improves.
   d. Strength increases.
   e. The older adult is less likely than a younger adult to regain full kidney function.
   f. Laboratory analysis (see Box 54-4)
   g. AKI can progress to chronic kidney disease (CKD).

The signs and symptoms of AKI are primarily caused by the retention of nitrogenous wastes, the retention of fluids, and the inability of the kidneys to regulate electrolytes.

D. Assessment: Assess objective and subjective data noted in the phases of AKI (see Box 54-4).
E. Other interventions
   1. Monitor vital signs, especially for signs of hypertension, tachycardia, tachypnea, and an irregular heart rate.
   2. Monitor urine and intake and output hourly and urine color and characteristics.
   3. Monitor daily weight (same scale, same
clothes, same time of day), noting that an increase of 0.5 to 1 lb/day (0.25 to 0.5 kg/day) indicates fluid retention.

4. Monitor for changes in the BUN, serum creatinine, and serum electrolyte levels.

5. Monitor for acidosis (may need to be treated with sodium bicarbonate).

7. Monitor for altered level of consciousness caused by uremia.

8. Monitor for signs of infection because the client may not exhibit an elevated temperature or an increased WBC count.

9. Monitor the lungs for wheezes and rhonchi and monitor for edema, which can indicate fluid overload.

10. Administer the prescribed diet, which is usually a low-to moderate-protein (to decrease the workload on the kidneys) and high-carbohydrate diet; ill clients may require nutritional support with supplements, enteral feedings, or parenteral nutrition.

11. Restrict potassium and sodium intake as prescribed based on the electrolyte level.

12. Administer medications as prescribed; be alert to the mechanism for metabolism and excretion of all prescribed medications.

13. Be alert to nephrotoxic medications, which may be prescribed (see Box 54-3).

14. Be alert to the PHCP’s adjustment of medication dosages for kidney injury.

15. Prepare the client for dialysis if prescribed; continuous renal replacement therapy may be used in AKI to treat fluid volume overload or rapidly developing azotemia and metabolic acidosis.

16. Provide emotional support by allowing opportunities for the client to express concerns and fears and by encouraging family interactions.

17. Promote consistency in caregivers.

18. Also refer to Section IV, E in this chapter (Special problems in kidney disease and interventions).
IV. Chronic Kidney Disease (CKD)

A. Description

1. CKD is a slow, progressive, irreversible loss in kidney function, with a GFR less than or equal to 60 mL per minute for 3 months or longer.
2. It occurs in stages (with loss of 75% of functioning nephrons, the client becomes symptomatic) and eventually results in uremia or end-stage kidney disease (with loss of 90% to 95% of functioning nephrons) (Table 54-2).
3. Hypervolemia can occur because of the kidneys’ inability to excrete sodium and water; hypovolemia can occur because of the kidneys’ inability to conserve sodium and water.

CKD affects all major body systems and may require dialysis or kidney transplantation to maintain life.

B. Primary causes

1. May follow AKI
2. Diabetes mellitus and other metabolic disorders
3. Hypertension
4. Chronic urinary obstruction
5. Recurrent infections
6. Renal artery occlusion
7. Autoimmune disorders

C. Assessment

1. Assess body systems for the manifestations of CKD (Box 54-5).
2. Assess psychological changes, which could include emotional lability, withdrawal, depression, anxiety, denial, dependence–independence conflict, changes in body image, and suicidal behavior.

D. Interventions

1. Same as the interventions for AKI.
2. Administer a prescribed diet, which is usually a moderate-protein (to decrease the workload on the kidneys) and high-carbohydrate, low-potassium, and low-phosphorus diet.
3. Provide oral care to prevent stomatitis and reduce discomfort from mouth sores.
4. Provide skin care to prevent pruritus.
5. Teach the client about fluid and dietary restrictions and the importance of daily weights.
6. Provide support to promote acceptance of the chronic
illness and prepare the client for long-term dialysis and transplantation, or explain to the client about her or his choice to decline dialysis or transplantation; with elderly clients, provide information that kidney function is declining and in time may reach end-stage renal disease and require dialysis; encourage healthy lifestyle and discuss choices.

E. Special problems in kidney disease and interventions (Box 54-6)

1. Activity intolerance and insomnia
   a. Fatigue results from anemia and the buildup of wastes from the diseased kidneys.
   b. Provide adequate rest periods.
   c. Teach the client to plan activities to avoid fatigue.
   d. Mild central nervous system (CNS) depressants may be prescribed to promote rest.

2. Anemia
   a. Anemia results from the decreased secretion of erythropoietin by damaged nephrons, resulting in decreased production of red blood cells.
   b. Monitor for decreased hemoglobin and hematocrit levels.
   c. Administer hematopoietics such as epoetin alfa or darbepoetin alfa, as prescribed to promote maturity of the red blood cells.
   d. Administer folic acid as prescribed.
   e. Administer iron orally as prescribed, but not at the same time as phosphate binders.
   f. Administer stool softeners as prescribed because of the constipating effects of iron.
   g. Note that oral iron is not well absorbed by the GI tract in CKD and causes nausea and vomiting; parenteral iron may be used if iron deficiencies persist despite folic acid or oral iron administration.
   h. Administer blood transfusions; prescribed only when necessary (acute
blood loss, symptomatic anemia), because they decrease the stimulus to produce red blood cells.

i. Blood transfusions also cause the development of antibodies against human tissues, which can make matching for organ transplantation difficult.

3. Gastrointestinal bleeding
a. Urea is broken down by the intestinal bacteria to ammonia; ammonia irritates the GI mucosa, causing ulceration and bleeding.
b. Monitor for decreasing hemoglobin and hematocrit levels.
c. Monitor stools for occult blood.
d. Avoid the administration of acetylsalicylic acid, because it is excreted by the kidneys; if administered, aspirin toxicity can occur and prolong the bleeding time.

Place the client with kidney disease on continuous telemetry. The client can develop hyperkalemia, resulting in the risk for dysrhythmias.

4. Hyperkalemia
a. Monitor vital signs for hypertension or hypotension and the apical heart rate; an irregular heart rate could indicate dysrhythmias.
b. Monitor the serum potassium level; an elevated serum potassium level can cause decreased cardiac output, heart blocks, fibrillation, or asystole (Fig. 54-1).
c. Provide a low-potassium diet (see Chapter 11 for a list of foods that are high in potassium).
d. Administer electrolyte-binding and electrolyte-excreting medications such as oral or rectal sodium polystyrene
sulfonate as prescribed to lower the serum potassium level.

e. Administer prescribed medications: 50% dextrose and regular insulin IV may be prescribed to shift potassium into the cells; calcium gluconate IV may be prescribed to reduce myocardial irritability from hyperkalemia; and sodium bicarbonate IV may be prescribed to correct acidosis.

f. Administer prescribed loop diuretics to excrete potassium.

g. Avoid potassium-retaining medications such as spironolactone and triamterene, because these medications will increase the potassium level.

h. Prepare the client for peritoneal dialysis (PD) or hemodialysis as prescribed.

5. Hypermagnesemia

a. Results from decreased renal excretion of magnesium.

b. Monitor for cardiac manifestations such as bradycardia, peripheral vasodilation, and hypotension.

c. Monitor CNS changes, such as drowsiness or lethargy.

d. Monitor neuromuscular manifestations, such as reduced or absent deep tendon reflexes or weak or absent voluntary skeletal muscle contractions.

e. Administer loop diuretics as prescribed to excrete magnesium.

f. Administer calcium as prescribed for resulting cardiac problems.

g. Avoid medications that contain magnesium, such as antacids; some laxatives and enemas may also contain magnesium.

h. During severe elevations, avoid foods that increase magnesium levels (see Chapter 11 for a list of foods that are high in magnesium).

6. Hyperphosphatemia

a. As the phosphorus level rises, the calcium level drops; this leads to the
stimulation of parathyroid hormone, causing bone demineralization.
b. Treatment is aimed at lowering the serum phosphorus level.
   c. Administer phosphate binders as prescribed with meals to lower serum phosphate levels.
   d. Administer stool softeners and laxatives as prescribed, because phosphate binders are constipating.
e. Teach the client about the need to limit the intake of foods high in phosphorus (see Chapter 11 for a list of foods that are high in phosphorus).

7. Hypertension
   a. Caused by failure of the kidneys to maintain BP homeostasis.
   b. Monitor vital signs for elevated BP.
   c. Maintain fluid and sodium restrictions as prescribed.
   d. Administer diuretics and antihypertensives as prescribed.

8. Hypervolemia
   a. Monitor vital signs for an elevated BP.
   b. Monitor intake and output and daily weight for indications of fluid retention.
   c. Monitor for periorbital, sacral, and peripheral edema.
   d. Monitor the serum electrolyte levels.
   e. Monitor for hypertension and notify the PHCP if there are sustained elevations.
   f. Monitor for signs of heart failure and pulmonary edema, such as restlessness, heightened anxiety, tachycardia, dyspnea, basilar lung crackles, and blood-tinged sputum; notify the PHCP immediately if signs occur.
   g. Maintain fluid restriction.
   h. Avoid the administration of large amounts of IV fluids.
   i. Administer diuretics as prescribed.
9. Hypocalcemia
   a. Results from a high phosphorus level and the inability of the diseased kidney to activate vitamin D
   b. The absence of vitamin D causes poor calcium absorption from the intestinal tract.
   c. Monitor the serum calcium level.
   d. Administer calcium supplements as prescribed.
   e. Administer activated vitamin D as prescribed.
   f. See Chapter 11 for a list of foods that are high in calcium.

10. Hypovolemia
    a. Monitor the vital signs for hypotension and tachycardia.
    b. Monitor for decreasing intake and output and a reduction in the daily weight.
    c. Monitor for dehydration.
    d. Monitor electrolyte levels.
    e. Provide replacement therapy based on the serum electrolyte level values.

11. Infection
    a. The client is at risk for infection caused by a suppressed immune system, dialysis access site, and possible malnutrition.
    b. Monitor for signs of infection.
    c. Avoid urinary catheters when possible; if used, provide catheter care per protocol.
    d. Provide strict asepsis during urinary catheter insertion and other invasive procedures.
    e. Instruct the client to avoid fatigue and avoid persons with infections.
    f. Administer antibiotics as prescribed,
monitoring for nephrotoxic effects.

12. Metabolic acidosis
   a. The kidneys are unable to excrete hydrogen ions or manufacture bicarbonate, resulting in acidosis.
   b. Administer alkalizers such as sodium bicarbonate as prescribed.
   c. Note that clients with CKD adjust to low bicarbonate levels and as a result do not become acutely ill.

13. Muscle cramps
   a. Occur from electrolyte imbalances and the effects of uremia on peripheral nerves
   b. Monitor serum electrolyte levels.
   c. Administer electrolyte replacements and medications to control muscle cramps as prescribed.
   d. Administer heat and massage as prescribed.

14. Neurological changes
   a. The buildup of active particles and fluids causes changes in the brain cells and leads to confusion and impairment in decision-making ability.
   b. Peripheral neuropathy results from the effects of uremia on peripheral nerves.
   c. Monitor the level of consciousness and for confusion.
   d. Monitor for restless leg syndrome, which is also common during dialysis treatments.
   e. Teach the client to examine areas of decreased sensation for signs of injury.

15. Ocular irritation
   a. Calcium deposits in the conjunctivae cause burning and watering of the eyes.
   b. Administer medications to control the calcium and phosphate levels as prescribed.
   c. Administer lubricating eye drops.
   d. Protect the client from injury.

16. Potential for injury
17. Pruritus

a. The client is at risk for fractures caused by alterations in the absorption of calcium, excretion of phosphate, and vitamin D metabolism.
b. Provide for a safe environment.
c. Avoid injury; tissue breakdown causes increased serum potassium levels.

18. Psychosocial problems

a. To rid the body of excess wastes, urate crystals are excreted through the skin, causing pruritus.
b. The deposit of urate crystals (uremic frost) occurs in advanced stages of kidney disease.
c. Monitor for skin breakdown, rash, and uremic frost.
d. Provide meticulous skin care and oral hygiene.
e. Avoid the use of soaps.
f. Administer antihistamines and antipruritics as prescribed to relieve itching.
g. Teach the client to keep the nails trimmed to prevent local infection from scratching.

V. Uremic Syndrome

A. Description: Systemic clinical and laboratory manifestations of severe and/or end-stage kidney disease due to accumulation of nitrogenous waste products in the blood caused by the kidneys’
inability to filter out these waste products.

B. Assessment

1. Oliguria
2. Presence of protein, red blood cells, and casts in the urine
3. Elevated levels of urea, uric acid, potassium, and magnesium in the urine
4. Hypotension or hypertension
5. Alterations in the level of consciousness
6. Electrolyte imbalances
7. Stomatitis
8. Nausea or vomiting
9. Diarrhea or constipation

C. Interventions

1. Monitor vital signs for hypertension, tachycardia, and an irregular heart rate.
2. Monitor serum electrolyte levels.
3. Monitor intake and output and for oliguria.
4. Provide a limited but high-quality protein diet as prescribed.
5. Provide a limited sodium, nitrogen, potassium, and phosphate diet as prescribed.
6. Assist the client to cope with body image disturbances caused by uremic syndrome.

VI. Hemodialysis

A. Description

1. Hemodialysis is an intermittent renal replacement therapy involving the process of cleansing the client’s blood.
2. It involves the diffusion of dissolved particles from 1 fluid compartment into another across a semipermeable membrane; the client’s blood flows through 1 fluid compartment of a dialysis filter, and the dialysate is in another fluid compartment.

B. Functions of hemodialysis

1. Cleanses the blood of accumulated waste products
2. Removes the byproducts of protein metabolism such as urea, creatinine, and uric acid from the blood
3. Removes excess body fluids
4. Maintains or restores the buffer system of the body
5. Corrects electrolyte levels in the body

C. Principles of hemodialysis

1. The semipermeable membrane is made of a thin, porous cellophane.
2. The pore size of the membrane allows small particles
to pass through, such as urea, creatinine, uric acid, and water molecules.

3. Proteins, bacteria, and some blood cells are too large to pass through the membrane.
4. The client’s blood flows into the dialyzer; the movement of substances occurs from the blood to the dialysate by the principles of osmosis, diffusion, and ultrafiltration.
5. Osmosis is the movement of fluids across a semipermeable membrane from an area of lower concentration of particles to an area of higher concentration of particles.
6. Diffusion is the movement of particles from an area of higher concentration to one of lower concentration.
7. Ultrafiltration is the movement of fluid across a semipermeable membrane as a result of an artificially created pressure gradient.

D. Dialysate bath
1. A dialysate bath is composed of water and major electrolytes.

2. The dialysate need not be sterile because bacteria and viruses are too large to pass through the pores of the semipermeable membrane; however, the dialysate must meet specific standards, and water is treated to ensure a safe water supply.

E. Interventions
1. Monitor vital signs before, during, and after dialysis; the client’s temperature may elevate because of slight warming of the blood from the dialysis machine (notify the PHCP about excessive temperature elevations because this could indicate sepsis, requiring blood cultures to be collected).
2. Monitor laboratory values, specifically the BUN, creatinine, and complete blood cell counts before, during, and after dialysis.
3. Assess the client for fluid overload before dialysis and fluid volume deficit following dialysis.
4. Weigh the client before and after dialysis to determine fluid loss. Note that the client will not urinate or will urinate small amounts (may be less than 30 mL/hr).
5. Assess the patency of the blood access device before, during, and after dialysis.
6. Monitor for bleeding; heparin is added to the dialysis bath to prevent clots from forming in the dialyzer or
the blood tubing.
7. Monitor for hypovolemia during dialysis, which can occur from blood loss or excess fluid and electrolyte removal.
8. Provide adequate nutrition; the client may eat before or during dialysis.
9. Identify the client’s reactions to the treatment and support coping mechanisms; encourage independence and involvement in care.

**Withhold antihypertensives and other medications that can affect the BP or result in hypotension until after hemodialysis treatment. Also withhold medications that could be removed by dialysis, such as water-soluble vitamins, certain antibiotics, and digoxin.**

VII. Access for Hemodialysis
   A. Subclavian and femoral catheters
      1. Description
         a. A subclavian (subclavian vein) or femoral (femoral vein) catheter may be inserted for short-term or temporary use in AKI.
         b. The catheter is used until a fistula or graft matures or develops, which is typically 6 weeks, or may be required when the client’s fistula or graft access has failed because of infection or clotting.
      2. Interventions
         a. Assess insertion site for hematoma, bleeding, catheter dislodgement, and infection.
         b. These catheters should only be used for dialysis treatments and accessed by dialysis personnel.
         c. Maintain an occlusive dressing over the catheter insertion site.
      3. Subclavian vein catheter
         a. The catheter is usually filled with heparin and capped to maintain patency between dialysis treatments. Heparin is aspirated from the line before dialysis.
         b. The catheter should not be uncapped except for dialysis treatments.
         c. The catheter may be left in place for up to 6 weeks if no complications occur.
4. Femoral vein catheter

a. Assess the extremity for circulation, temperature, and pulses.
b. Prevent pulling or disconnecting of the catheter when giving care.
c. Because the groin is not a clean site, meticulous perineal care is required.
d. Use an IV infusion pump or controller with microdrip tubing if a heparin infusion through the catheter to maintain patency is prescribed.

The client with a femoral vein catheter should not sit up more than 45 degrees or lean forward, because the catheter may kink and occlude.

B. External arteriovenous shunt (Fig. 54-2)

1. Description

a. Two Silastic cannulas are surgically inserted into an artery and vein in the forearm or leg to form an external blood path.
b. The cannulas are connected to form a U shape; blood flows from the client’s artery through the shunt into the vein.
c. A tube leading to the membrane compartment of the dialyzer is connected to the arterial cannula.
d. Blood fills the membrane compartment, passes through the dialyzer, and is returned to the client through a tube connected to the venous cannula.
e. When dialysis is complete, the cannulas are clamped and reattached, reforming the U shape.

2. Advantages

a. The external arteriovenous shunt can be used immediately following its creation.
b. No venipuncture is necessary for dialysis.

3. Disadvantages

a. Disconnection or dislodgment of the external shunt
b. Risk of hemorrhage, infection, or clotting
c. Potential for skin erosion around the catheter site

4. Interventions

a. Avoid getting the shunt wet.
b. Wrap a dressing completely around the shunt and keep it dry and intact.
c. Keep cannula clamps at the client’s bedside or attached to the arteriovenous dressing for use in case of accidental disconnection.
d. Teach the client that the shunt extremity should not be used for monitoring BP, drawing blood, placing IV lines, or administering injections.
e. Fold back the dressing to expose the shunt tubing and assess for signs of hemorrhage, infection, or clotting.
f. Monitor skin integrity around the insertion site.
g. Auscultate for a bruit and palpate for a thrill, although a bruit may not be heard with the shunt.
h. Notify the PHCP immediately if signs of clotting, hemorrhage, or infection occur.

5. Signs of clotting

a. Fibrin: White flecks in the tubing
b. Separation of serum and cells
c. Absence of a previously heard bruit; thrill absent on palpation
d. Coolness of the tubing or extremity
e. Tingling sensation at site or in extremity

C. Internal arteriovenous fistula (see Fig. 54-2)

1. Description

a. A permanent access of choice for the client with CKD requiring dialysis.
b. The fistula is created surgically by anastomosis of a large artery and large vein in the arm.
c. The flow of arterial blood into the venous system causes the vein to become engorged (matured or developed).
d. Maturity takes about 4 to 6 weeks, depending on the client’s ability to do hand-flexing exercises such as ball squeezing, which help the fistula mature.
e. The fistula is required to be mature before it can be used, because the engorged vein is punctured with a large-bore needle for the dialysis procedure.
f. Subclavian or femoral catheters, PD, or an external arteriovenous shunt can be used for dialysis while the fistula is maturing or developing.
g. Avoid taking BP or performing venipuncture for intravenous access or lab draws to protect the integrity of the fistula.
h. Fistulas are dressed with pressure dressings after hemodialysis to prevent bleeding. Ensure the removal of the pressure dressing within the prescribed time frame or according to agency policy.

2. Advantages
   a. Because the fistula is internal, the risk of clotting and bleeding is low.
   b. The fistula can be used indefinitely.
   c. The fistula has a decreased incidence of infection, because it is internal and is not exposed.
   d. Once healing has occurred, no external dressing is required.
   e. The fistula allows freedom of movement.

3. Disadvantages
   a. The fistula cannot be used immediately after insertion, so planning ahead for an alternative access for dialysis is important.
   b. Needle insertions through the skin and tissues to the fistula are required for dialysis.
   c. Infiltration of the needles during dialysis can occur and cause hematomas.
   d. An aneurysm can form in the fistula.
   e. Heart failure can occur from the
increased blood flow in the venous system.

Arterial steal syndrome can develop in a client with an internal arteriovenous fistula. In this complication, too much blood is diverted to the vein, and arterial perfusion to the hand is compromised.

D. Internal arteriovenous graft (see Fig. 54-2)
1. Description
   a. The internal graft may be used for chronic dialysis clients who do not have adequate blood vessels for the creation of a fistula.
   b. An artificial graft made of Gore-Tex or a bovine (cow) carotid artery is used to create an artificial vein for blood flow.
   c. The procedure involves the anastomosis of an artery to a vein, using an artificial graft.
   d. The graft can be used 2 weeks after insertion.
   e. Complications of the graft include clotting, aneurysms, and infection.
2. Advantages and disadvantages: Same as for internal arteriovenous fistula

E. Interventions for an arteriovenous fistula and arteriovenous graft
1. Teach the client that the extremity should not be used for monitoring BP, drawing blood, placing IV lines, or administering injections, and that the client should inform all health care personnel of its presence.
2. Teach the client with an arteriovenous fistula to perform hand-flexing exercises such as ball squeezing (if prescribed) to promote graft maturity.
3. Note the temperature and capillary refill of the extremity.
4. Palpate pulses below the fistula or graft, and monitor for hand swelling as an indication of ischemia.
5. Monitor for clotting.
   a. Complaints of tingling or discomfort in the extremity
   b. Inability to palpate a thrill or auscultate a bruit over the fistula or graft
7. Monitor for infection.
8. Monitor lung and heart sounds for signs of heart
failure.
9. Notify the PHCP immediately if signs of clotting, infection, or arterial steal syndrome occur.

To ensure patency, palpate for a thrill or auscultate for a bruit over the fistula or graft. Notify the PHCP if a thrill or bruit is absent.

VIII. Complications of Hemodialysis (Box 54-7)
A. If signs of complications occur, the dialysis is slowed or stopped, depending on the complication, and the PHCP is notified immediately.
B. The nurse stays with the client and monitors the client, including vital signs, while another nurse obtains initial prescriptions from the PHCP.
C. See Priority Nursing Actions for air embolism.

Priority Nursing Actions

Air Embolism in a Client Receiving Hemodialysis

1. Stop the hemodialysis.
2. Turn the client on the left side, with the head down (Trendelenburg’s position).
3. Notify the primary health care provider (PHCP) and Rapid Response Team for the hospitalized client.
4. Administer oxygen.
5. Assess vital signs and pulse oximetry.
6. Document the event, actions taken, and the client’s response.

Reference

IX. Peritoneal Dialysis
A. Description
1. The peritoneum acts as the dialyzing membrane (semipermeable membrane) to achieve dialysis, and the membrane is accessed by insertion of a PD catheter through the abdomen.
2. PD works on the principles of osmosis, diffusion, and ultrafiltration; PD occurs via the transfer of fluid and solute from the bloodstream through the peritoneum into the dialysate solution.
3. The peritoneal membrane is large and porous, allowing solutes and fluid to move via osmosis from an area of higher concentration in the body to an area
of lower concentration in the dialyzing fluid.
4. The peritoneal cavity is rich in capillaries; therefore, it provides a ready access to the blood supply.

B. Contraindications to PD
1. Peritonitis
2. Recent abdominal surgery
3. Abdominal adhesions
4. Other GI problems such as diverticulosis

C. Access for PD (Fig. 54-3)
1. A siliconized rubber catheter such as a Tenckhoff catheter is surgically inserted into the client’s peritoneal cavity to allow infusion of dialysis fluid; the catheter site is covered by a sterile dressing that is changed daily and when soiled or wet.
2. The preferred insertion site is 3 to 5 cm below the umbilicus; this area is relatively avascular and has less fascial resistance.
3. The catheter is tunneled under the skin, through the fat and muscle tissue to the peritoneum; it is stabilized with inflatable Dacron cuffs in the muscle and under the skin.
4. Over a period of 1 to 2 weeks following insertion, fibroblasts and blood vessels grow around the cuffs, fixing the catheter in place and providing an extra barrier against dialysate leakage and bacterial invasion.
5. If the client is scheduled for transplant surgery, the PD catheter may be either removed or left in place if the need for dialysis is suspected post-transplantation.

D. Dialysate solution
1. The solution is sterile.
2. All dialysis solutions are prescribed by the PHCP; the solution contains electrolytes and minerals and has a specific osmolarity, specific glucose concentration, and other medication additives as prescribed.
3. The higher the glucose concentration, the greater the hypertonicity and the amount of fluid removed during a PD exchange.
4. Increasing the glucose concentration increases the concentration of active particles that cause osmosis, increases the rate of ultrafiltration, and increases the amount of fluid removed.
5. If hyperkalemia is not a problem, potassium may be added to each bag of dialysate solution.
6. Heparin is added to the dialysate solution to prevent clotting of the catheter.
7. Prophylactic antibiotics may be added to the dialysate solution to prevent peritonitis.
8. Insulin may be added to the dialysate solution for the client with diabetes mellitus.

E. PD infusion

1. Description
   a. One infusion (fill), dwell, and drain is considered 1 exchange.
   b. Fill: 1 to 2 L of dialysate as prescribed is infused by gravity into the peritoneal space, which usually takes 10 to 20 minutes.
   c. Dwell time: The amount of time that the dialysate solution remains in the peritoneal cavity is prescribed by the PHCP and can last 20 to 30 minutes to 8 or more hours, depending on the type of dialysis used.
   d. Drain (outflow): Fluid drains out of body by gravity into the drainage bag.

2. Interventions before treatment
   a. Monitor vital signs.
   b. Monitor daily weight on the same scale.
   c. Have the client void, if possible.
   d. Assess electrolyte and glucose levels.
   e. Assess the peritoneal catheter dressing and site.

3. Interventions during treatment
   a. Monitor vital signs.
   b. Monitor for respiratory distress, pain, or discomfort.
   c. Monitor for signs of pulmonary edema.
   d. Monitor for hypotension and hypertension.
   e. Monitor for malaise, nausea, and vomiting.
   f. Assess the catheter site dressing for wetness or bleeding.
   g. Monitor dwell time as prescribed by the PHCP.
   h. Do not allow dwell time to
extend beyond the PHCP’s prescription, because this increases the risk for hyperglycemia.
i. Initiate outflow; turn the client from side to side if the outflow is slow to start.
j. Monitor outflow, which should be a continuous stream after the clamp is opened.
k. Monitor outflow for color and clarity.
l. Monitor intake and output accurately; if outflow is less than inflow, the difference is equal to the amount absorbed or retained by the client during dialysis and should be counted as intake.
m. An outflow greater than inflow as well as the appearance of frank blood or cloudiness in the outflow should be reported to the PHCP.

F. Types of PD

1. Continuous ambulatory peritoneal dialysis (CAPD)

a. Closely resembles renal function because it is a continuous process
b. Does not require a machine for the procedure
c. Promotes client independence
d. The client performs self-dialysis 24 hours a day, 7 days a week.
e. Four dialysis cycles are usually administered in a 24-hour period, including an overnight 8-hour dwell time.
f. Dialysate, 1.5 to 2 L, is instilled into the abdomen 4 times daily and allowed to dwell as prescribed (bags are weighed to determine output); the catheter is clamped and the bag is rolled up during dwell time.
g. After dwell, the bag is placed lower than the insertion site and the clamp is opened so that fluid drains out by gravity flow.
h. After fluid is drained, the bag is changed, new dialysate is instilled into the abdomen, and the process
continues.

i. Between exchanges, the catheter is clamped.

2. Automated peritoneal dialysis (Box 54-8)
   a. Automated dialysis requires a peritoneal cycling machine.
   b. Automated dialysis can be done as intermittent peritoneal dialysis, continuous cycling peritoneal dialysis, or nightly peritoneal dialysis.
   c. The exchanges are automated instead of manual.

X. Complications of Peritoneal Dialysis

Infection is a concern with PD; sites of infection are either the catheter insertion site or the peritoneum, causing peritonitis.

A. Peritonitis

1. Monitor for signs and symptoms of peritonitis: Fever, cloudy outflow, rebound abdominal tenderness, abdominal pain, general malaise, nausea, and vomiting.
2. Cloudy or opaque outflow is an early sign of peritonitis.
3. If peritonitis is suspected, obtain a sample for culture and sensitivity of the outflow to determine the infective organism.
4. Antibiotics may be added to the dialysate.
5. Avoid infections by maintaining meticulous sterile technique when connecting and disconnecting PD solution bags and when caring for the catheter insertion site.
6. Prevent the catheter insertion site dressing from becoming wet during care of the client or the dialysis procedure; change the dressing if wet or soiled.
7. Follow institutional procedure for connecting and disconnecting PD solution bags, which may include scrubbing the connection sites with an antiseptic solution.

B. Abdominal pain

1. Peritoneal irritation during inflow commonly causes abdominal cramping and discomfort during the first few exchanges; the pain usually disappears after 1 to 2 weeks of dialysis treatments.
2. Warm the dialysate before administration,
using a special dialysate warmer pad, because the cold temperature of the dialysate can cause discomfort.

C. Abnormal outflow characteristics indicative of complications
1. Bloody outflow after the first few exchanges indicates vascular complications (the outflow should be clear after the initial exchanges).
3. Urine-colored outflow indicates bladder perforation.
4. Cloudy outflow indicates peritonitis.

D. Insufficient outflow
1. The main cause of insufficient outflow is a full colon; encourage a high-fiber diet, because constipation can cause inflow and outflow problems. Administer stool softeners as prescribed.
2. Insufficient outflow may also be caused by catheter migration out of the peritoneal area; if this occurs, an x-ray will be prescribed to evaluate catheter position.
3. Maintain the drainage bag below the client’s abdomen.
4. Check for kinks in the tubing.
5. Change the client’s outflow position by turning the client to a side-lying position or ambulating the client.
6. Check for fibrin clots in the tubing and milk the tubing to dislodge the clot as prescribed.

E. Leakage around the catheter site
1. Clear fluid that leaks from the catheter exit site will be noted.
2. It takes 1 to 2 weeks following insertion of the catheter before fibroblasts and blood vessels grow into the catheter cuffs, which fix it in place and provide an extra barrier against dialysate leakage and bacterial invasion.
3. Smaller amounts of dialysate need to be used; it may take up to 2 weeks for the client to tolerate a full 2-L exchange without leaking around the catheter site.

XI. Kidney Transplantation (Fig. 54-4)
A. Description
1. A human kidney from a compatible donor is implanted into a recipient.
2. Kidney transplantation is performed for irreversible kidney failure; specific criteria are established for
eligibility for a transplant.

3. The recipient must take immunosuppressive medications for life.

B. Donors

1. Donors may be living donors (related or unrelated to the client), non-heart-beating donors (NHBDs), or cadaver donors.
2. The most desirable source of kidneys for transplantation is living related donors who closely match the client.
3. Non-heart-beating donors are those who have been declared dead by cardiopulmonary criteria and have organs harvested immediately after death; these persons have consented previously to organ donation.
4. Cadaver donors are those who have suffered irreversible brain injury; these persons are maintained with mechanical ventilation and must have adequate perfusion to the kidneys.
5. Physical criteria for donors include absence of systemic disease and infection, no history of cancer, no kidney disease or hypertension, and adequate kidney function.
6. Donors are screened for ABO blood group, tissue-specific antigen, human leukocyte antigen suitability, and mixed lymphocyte culture index (histocompatibility); donors are also screened for the presence of any communicable diseases and undergo a complete medical evaluation as well as a nephrology consultation.
7. The donor must be in excellent health, with 2 properly functioning kidneys.
8. The emotional well-being of the donor is determined.
9. Complete understanding of the donation process and outcome by the donor is necessary; usually kidney removal from the donor is done using a laparoscopic procedure.

C. Preoperative interventions

1. Verify histocompatibility tests of donor, which will be done by organ bank personnel.
2. Administer immunosuppressive medications to the recipient as prescribed.
3. Maintain strict aseptic technique.
4. Verify that hemodialysis of the recipient was completed 24 hours before transplantation.
5. Ensure that the recipient is free of any infections.
6. Assess renal function studies.
7. Encourage discussion of feelings of the live donor and the recipient.
8. Provide psychological support to the live donor, NHBD, or cadaver donor family and to the recipient.

D. Postoperative interventions for the recipient

1. The transplanted kidney is placed in the anterior iliac fossa; usually the recipient’s diseased kidneys are left in place, except for those with polycystic kidney disease, in which the kidneys are often very enlarged and painful.
2. Urine output usually begins immediately if the donor was a living donor; it may be delayed for a few days or more with other donor types.
3. Hemodialysis may be performed until adequate kidney function is established.
4. Monitor vital signs and for signs of complications such as rejection, thrombosis, renal artery stenosis, or wound problems.
5. Monitor urine output hourly; immediately report an abrupt decrease in output.
6. Monitor IV fluids closely; for the first 12 to 24 hours, IV fluid replacement is based on hourly urine output.
7. Administer prescribed diuretics and osmotic agents.
8. Monitor daily weight to evaluate fluid status.
9. Monitor daily laboratory results to evaluate renal function, including hematocrit, BUN, and serum creatinine levels, and monitor urine for blood and specific gravity.
10. Position the client in a semi-Fowler’s position to promote gas exchange, turning from the back to the nonoperative side.
11. Monitor urinary catheter patency; the urinary catheter usually remains in the bladder for 3 to 5 days to allow for anastomosis healing; it is removed as soon as possible to prevent infection.
12. Note that urine is pink and may be bloody initially but gradually returns to normal within several days to weeks.
13. Notify the PHCP if gross hematuria and clots are noted in the urine.
14. Monitor the 3-way bladder irrigation, if present, for clots; irrigate only if an PHCP’s prescription is present.
15. Maintain aseptic technique and monitor for infection.
17. Monitor for bowel sounds and for the passage of flatus; initiate a specific diet and oral fluids as prescribed when flatus and bowel sounds return (usually, fluids, sodium, and potassium are restricted if the client is oliguric).

18. Maintain good oral hygiene, monitoring for stomatitis and bacterial and fungal infections.

19. Encourage coughing and deep-breathing exercises.

20. Administer immunosuppressive medications as prescribed.

22. Promote relationship between the live donor and recipient.

23. Monitor both the donor and the recipient for depression.

24. Provide the recipient with instructions following the kidney transplantation (Box 54-9).

25. Assist the recipient to cope with the body image disturbances that occur from long-term use of immunosuppressants.

26. Advise the recipient of available support groups.

E. Graft rejection

1. Assessment (Box 54-10)

2. Hyperacute rejection
   a. Hyperacute rejection occurs within 48 hours after the transplant.
   b. Intervention: Removal of rejected kidney

3. Acute rejection
   a. Occurs within 1 week postoperatively, but can occur any time post-transplantation.
   b. Intervention: Potentially reversible with increased immunosuppressive therapy.

4. Chronic rejection
   a. Occurs slowly months to years after transplant.
   b. Interventions: Immunosuppressive medications and dialysis if necessary.

Except in identical twin donors and recipients, the major postoperative complication following renal transplant is graft rejection.

XII. Cystitis (Urinary Tract Infection)
A. Description
1. Cystitis (urinary tract infection [UTI]) is an inflammation of the bladder from an infection, obstruction of the urethra, or other irritants (Box 54-11).
2. The most common causative organisms are *Escherichia coli* and *Enterobacter, Pseudomonas*, and *Serratia* species.
3. Cystitis is more common in women, because women have a shorter urethra than men and the urethra in the woman is located close to the rectum.
4. Sexually active and pregnant women are most vulnerable to cystitis.

B. Assessment
1. Frequency and urgency
2. Burning on urination
3. Voiding in small amounts
4. Inability to void
5. Incomplete emptying of the bladder
6. Lower abdominal discomfort or back discomfort; bladder spasms
7. Cloudy, dark, foul-smelling urine
8. Hematuria
9. Malaise, chills, fever
10. WBC count greater than 11,000 mm$^3$ (11.0 × 10$^9$/L) on urinalysis

*Altered mentation is a sign of a UTI in older adults; frequency and urgency may not be specific symptoms of UTI because of urinary elimination changes that occur with aging.*

C. Interventions
1. Before administering prescribed antibiotics, obtain a urine specimen for culture and sensitivity, if prescribed, to identify bacterial growth.
2. Encourage the client to increase fluids up to 3000 mL/day, especially if the client is taking a sulfonamide; sulfonamides can form crystals in concentrated urine.
3. Administer prescribed medications, which may include analgesics, antiseptics, antispasmodics, antibiotics, and antimicrobials.
4. Maintain an acid urine pH (5.5); instruct the client about foods to consume to maintain acidic urine.
5. Provide heat to the abdomen or sitz baths for complaints of discomfort.
6. Note that if the client is prescribed an aminoglycoside, sulfonamide, or nitrofurantoin, the actions of these medications are decreased by acidic urine.
7. Use sterile technique when inserting a urinary catheter.
8. Provide meticulous perineal care for the client with an indwelling catheter.
9. Discourage caffeine products such as coffee, tea, and cola.

10. Client education
   a. Avoid alcohol.
   b. Take medications as prescribed.
   c. Take antibiotics on schedule and complete the entire course of medications as prescribed, which may be 10 to 14 days.
   d. Repeat the urine culture following treatment.
   e. Prevent recurrence of cystitis (Box 54-12).

XIII. Urethritis

A. Description
   1. Inflammation of the urethra commonly associated with a sexually transmitted infection (STI); may occur with cystitis.
   2. In men, urethritis most often is caused by gonorrhea or chlamydial infection.
   3. In women, urethritis most often is caused by feminine hygiene sprays, perfumed toilet paper or sanitary napkins, spermicidal jelly, UTI, or changes in the vaginal mucosal lining.

B. Assessment
   1. Pain or burning on urination
   2. Frequency and urgency
   3. Nocturia
   4. Difficulty voiding
   5. Males may have clear to mucopurulent discharge from the penis.
   6. Females may have lower abdominal discomfort.

C. Interventions
   1. Encourage fluid intake.
   2. Prepare the client for testing to determine whether an STI is present.
   3. Administer antibiotics as prescribed.
   4. Instruct the client in the administration of sitz or tub baths.
   5. If stricture occurs, prepare the client for dilation of the
urethra and instillation of an antiseptic solution.
6. Instruct the female client to avoid the use of perfumed
toilet paper or sanitary napkins and feminine hygiene
sprays.
7. Instruct the client to avoid intercourse until the
symptoms subside or treatment of the STI is
complete.
8. Instruct the client about STIs if this is the cause.
   a. Prevent STIs by the use of latex
      condoms or abstinence.
   b. All sexual partners during the 30 days
      before diagnosis with chlamydial
      infection should be notified, examined,
      and treated if indicated.
   c. Chlamydial infection often coexists with
      gonorrhea; diagnostic testing is done
      for both STIs.
   d. Treatment for STIs includes antibiotics
      as prescribed to treat the causative
      organism.
   e. A serious primary complication of
      chlamydial infection is sterility.
   f. Follow-up culture may be requested in 4
to 7 days to evaluate the effectiveness
of medications.

XIV. Ureteritis
   A. Description: An inflammation of the ureter commonly associated
      with bacterial or viral infections and pyelonephritis
   B. Assessment
   C. Interventions
      1. Dysuria
      2. Frequent urination
      3. Clear to mucopurulent penile discharge in males
      4. Treatment includes identifying and treating the
         underlying cause and providing symptomatic relief.
      5. Metronidazole or clotrimazole may be prescribed for
         treating Trichomonas infection.
      6. Nystatin or fluconazole may be prescribed for treating
         yeast infections.
      7. Doxycycline or azithromycin may be prescribed for
         treating chlamydial infections.

XV. Pyelonephritis
   A. Description
      1. An inflammation of the renal pelvis and the
         parenchyma, commonly caused by bacterial invasion
      2. Acute pyelonephritis often occurs after bacterial
         contamination of the urethra or following an invasive
         procedure of the urinary tract.
3. Chronic pyelonephritis most commonly occurs following chronic urinary flow obstruction with reflux.
4. *E. coli* is the most common causative bacterial organism.

B. Acute pyelonephritis
1. Acute pyelonephritis occurs as a new infection or recurs as a relapse of a previous infection.
2. It can progress to bacteremia or chronic pyelonephritis.
3. Assessment
   a. Fever and chills
   b. Tachycardia and tachypnea
   c. Nausea
   d. Flank pain on the affected side
   e. Costovertebral angle tenderness
   f. Headache
   g. Dysuria
   h. Frequency and urgency
   i. Cloudy, bloody, or foul-smelling urine
   j. Increased WBCs in the urine

C. Chronic pyelonephritis
1. A slow, progressive disease usually associated with recurrent acute attacks
2. Causes contraction of the kidney and dysfunction of the nephrons, which are replaced by scar tissue
3. Causes the ureter to become fibrotic and narrowed by strictures
4. Can lead to AKI or CKD
5. Assessment
   a. Frequently diagnosed incidentally when a client is being evaluated for hypertension
   b. Inability to conserve sodium
   c. Poor urine-concentrating ability
   d. Pyuria
   e. Azotemia
   f. Proteinuria

D. Interventions
1. Monitor vital signs, especially for elevated temperature.
2. Encourage fluid intake up to 3000 mL/day to reduce fever and prevent dehydration.
3. Monitor intake and output (ensure that output is a minimum of 1500 mL in 24 hours).
5. Encourage adequate rest.
6. Instruct the client about a high-calorie, low-protein
diet.
7. Provide warm, moist compresses to the flank area to help relieve pain.
8. Encourage the client to take warm baths for pain relief.
9. Administer analgesics, antipyretics, antibiotics, urinary antiseptics, and antiemetics as prescribed.
10. Monitor for signs of AKI or CKD.
11. Encourage follow-up urine culture.

XVI. Glomerulonephritis: Refer to Chapter 37

XVII. Nephrotic Syndrome: Refer to Chapter 37

XVIII. Polycystic Kidney Disease
  A. Description
  1. Cyst formation and hypertrophy of the kidneys, which leads to cystic rupture, infection, formation of scar tissue, and damaged nephrons
  2. There is no specific treatment to arrest the progress of the destructive cysts.
  3. The ultimate result of this disease is CKD.

  B. Types
  1. Infantile polycystic disease: An inherited autosomal recessive trait that results in the death of the infant within a few months after birth
  2. Adult polycystic disease: An autosomal dominant trait that manifests between 30 and 40 years of age and results in end-stage kidney disease.

  C. Assessment
  1. Often asymptomatic until the age of 30 to 40 years
  2. Flank, lumbar, or abdominal pain that worsens with activity and is relieved when lying down
  3. Fever and chills
  4. Recurrent UTIs
  5. Hematuria, proteinuria, pyuria
  6. Calculi
  7. Hypertension
  8. Palpable abdominal masses and enlarged kidneys
  9. Increased abdominal girth

  D. Interventions
  1. Monitor for gross hematuria, which indicates cyst rupture.
  2. Increase sodium and water intake because sodium loss rather than retention occurs.
  3. Provide bed rest if ruptured cysts and bleeding occur.
  4. Monitor pain, teach use of pain medications (avoid nonsteroidal antiinflammatory drugs [NSAIDs] and
aspirin because of the risk for bleeding), and use dry heat to abdomen and flank areas for comfort when cysts are infected.

5. Prevent constipation from pressure of cysts on colon by adequate fiber in diet, stool softeners, adequate fluid intake, and exercise.

6. Prepare the client for percutaneous cyst puncture for relief of obstruction or for draining an abscess.

7. Administer antihypertensives as prescribed.

8. Prevent and/or treat UTIs.

9. Prepare the client for dialysis or renal transplantation.

10. Encourage the client to seek genetic counseling.

11. Provide psychological support to the client and family.

12. Provide psychosocial support and genetic counseling for family members without polycystic kidney disease who may want to donate a kidney.

XIX. Hydronephrosis
   A. Description (Fig. 54-5)
   1. Distention of the renal pelvis and calices caused by an obstruction of normal urine flow
   2. The urine becomes trapped proximal to the obstruction.
   3. The causes include calculus, tumors, scar tissue, ureter obstructions, and hypertrophy of the prostate.

   B. Assessment
   1. Hypertension
   2. Headache
   3. Colicky or dull flank pain that radiates to the groin

   C. Interventions
   1. Monitor vital signs frequently.
   2. Monitor for fluid and electrolyte imbalances, including dehydration after the obstruction is relieved.
   3. Monitor for diuresis, which can lead to fluid depletion.
   5. Monitor urine for specific gravity and albumin and glucose levels.
   6. Administer fluid replacement as prescribed.
   7. Prepare the client for insertion of a nephrostomy tube or a surgical procedure to relieve the obstruction if prescribed.

XX. Renal Calculi
   A. Description
   1. Calculi are stones that can form anywhere in the
urinary tract; however, the most frequent site is the kidneys.

2. Problems resulting from calculi are severe intermittent pain, obstruction, tissue trauma, secondary hemorrhage, and infection.

3. The stone can be located through radiography of the kidneys, ureters, and bladder; IV pyelography; computed tomography (CT) scanning; and renal ultrasonography.

4. A stone analysis is done after passage to determine the type of stone and assist in determining treatment.

5. **Urolithiasis** refers to the formation of urinary calculi; these form in the ureters.

6. **Nephrolithiasis** refers to the formation of kidney calculi; these form in the renal parenchyma.

7. When a calculus occludes the ureter and blocks the flow of urine, the ureter dilates, producing hydroureter (see Fig. 54-5).

8. If the obstruction is not removed, urinary stasis results in infection, impairment of renal function on the side of the blockage, hydronephrosis (see Fig. 54-5), and irreversible kidney damage.

B. Causes

1. Family history of stone formation
2. Diet high in calcium, vitamin D, protein, oxalate, purines, or alkali
3. Obstruction and urinary stasis
4. Dehydration
5. Use of diuretics, which can cause volume depletion
6. UTIs and prolonged urinary catheterization
7. Immobilization
8. Hypercalcemia and hyperparathyroidism
9. Elevated uric acid level, such as in gout

C. Assessment

1. Renal colic, which originates in the lumbar region and radiates around the side and down to the testicles in men and to the bladder in women
2. Ureteral colic, which radiates toward the genitalia and thighs
3. Sharp, severe pain of sudden onset
4. Dull, aching pain in the kidney
5. Nausea and vomiting, pallor, and diaphoresis during acute pain
6. Urinary frequency, with alternating retention
7. Signs of a UTI
8. Low-grade fever
9. High numbers of red blood cells, WBCs, and bacteria noted in the urinalysis report
10. Gross hematuria

D. Interventions

1. Monitor vital signs, especially temperature, for signs of infection.
2. Monitor intake and output.
3. Assess for fever, chills, and infection.
4. Monitor for nausea, vomiting, and diarrhea.
5. Encourage fluid intake up to 3000 mL/day, unless contraindicated, to facilitate the passage of the stone and prevent infection; monitor for obstruction.
6. Administer fluids intravenously as prescribed if unable to take fluids orally or in adequate amounts to increase the flow of urine and facilitate passage of the stone.
7. Provide warm baths and heat to the flank area (massage therapy should be avoided).
8. Administer analgesics at regularly scheduled intervals as prescribed to relieve pain.
9. Assess the client’s response to pain medication.
10. Assist the client in performing relaxation techniques to assist in relieving pain.
11. Encourage client ambulation, if stable, to promote the passage of the stone.
12. Turn and reposition the immobilized client to promote passage of the stone.
13. Instruct the client in the diet restrictions specific to the stone composition if prescribed (Box 54-13).
14. Prepare the client for surgical procedures if prescribed.

For the client with renal calculi, strain all urine for the presence of stones and send the stones to the laboratory for analysis.

XXI. Treatment Options for Renal Calculi (Fig. 54-6)

A. Cystoscopy

1. Cystoscopy may be done for stones in the bladder or lower ureter.
2. One or two ureteral catheters are inserted past the stone.
3. The catheters are left in place for 24 hours to drain the urine trapped proximal to the stone and to dilate the ureter.
4. A continuous chemical irrigation may be prescribed to
dissolve the stone.

B. Extracorporeal shock wave lithotripsy (ESWL)
1. A noninvasive mechanical procedure for breaking up stones located in the kidney or upper ureter so that they can pass spontaneously or be removed by other methods.
2. A stent may be placed to facilitate passing stone fragments.
3. Fluoroscopy is used to visualize the stone, and ultrasonic waves are delivered to the area of the stone to disintegrate it.
4. The stones are passed in the urine within a few days.
5. The client is taught to watch for signs of urinary obstruction, bleeding, or hematoma formation.
6. Instruct the client to increase fluid intake to flush out the stone fragments.

C. Percutaneous lithotripsy
1. An invasive procedure in which a guide is inserted under fluoroscopy near the area of the stone; an ultrasonic wave is aimed at the stone to break it into fragments.
2. Percutaneous lithotripsy may be performed via cystoscopy or nephroscopy (a small flank incision is needed for nephroscopy).
3. The client might have an indwelling urinary catheter.
4. A nephrostomy tube may be placed to administer chemical irrigations to break up the stone; the nephrostomy tube may remain in place for 1 to 5 days.
5. Encourage the client to drink 3000 to 4000 mL of fluid per day as prescribed following the procedure.
6. Instruct the client to monitor for complications of infection, hemorrhage, and extravasation of fluid into the retroperitoneal cavity.

D. Ureterolithotomy
1. An open surgical procedure performed if lithotripsy is not effective for removal of a stone in the ureter.
2. An incision is made through the lower abdomen or flank and then into the ureter to remove the stone.
3. The client may have a drain, ureteral stent catheter, and/or indwelling bladder catheter.

E. Pyelolithotomy and nephrolithotomy
1. Pyelolithotomy is an incision into the renal pelvis to
remove a stone; a large flank incision is required, and
the client may have a drain and indwelling bladder catheter.

2. Nephrolithotomy is an incision into the kidney made
to remove a stone; a large flank incision is required,
and the client may have a nephrostomy tube and an
indwelling bladder catheter.

F. Partial or total nephrectomy
1. Performed for extensive kidney damage, renal
infection, severe obstruction from stones or tumors,
and prevention of stone recurrence

2. Monitor the incision, particularly if a drain is
in place, because it will drain large amounts of urine.

3. Protect the skin from urinary drainage,
changing dressings frequently if necessary; place an
ostomy pouch over the drain to protect the skin if
urinary drainage is excessive.

4. Monitor the nephrostomy tube, which may be
attached to a drainage bag, for a continuous flow of
urine.

5. Do not irrigate the nephrostomy or bladder
catheters unless specifically prescribed.

6. Encourage fluid intake to ensure a urine
output of 2500 to 3000 mL/day or more as prescribed.

XXII. Kidney Tumors
A. Description
1. Kidney tumors may be benign or malignant, bilateral
or unilateral.

2. Common sites of metastasis of malignant tumors
include bone, lungs, liver, spleen, and the other
kidney.

3. The exact cause of renal carcinoma is unknown.

B. Assessment
1. Dull flank pain
2. Palpable renal mass
3. Painless gross hematuria

C. Radical nephrectomy
1. Description
a. Surgical removal of the entire kidney,
adjacent adrenal gland, and renal
artery and vein
b. Radiation therapy and possibly
chemotherapy may follow radical

1863
nephrectomy.
c. Before surgery, radiation may be used
to embolize (occlude) the arteries
supplying the kidney to reduce
bleeding during nephrectomy.

2. Postoperative interventions
   a. Monitor vital signs for signs of bleeding
      (hypotension and tachycardia).
   b. Monitor for abdominal
distention, decreases in urinary output,
and alterations in level of
consciousness as signs of bleeding;
check the bed linens under the client
for bleeding.
   c. Monitor for signs of adrenal
   insufficiency, which include a large
   urinary output followed by
   hypotension and subsequent oliguria.
   d. Administer fluids and packed red
   blood cells intravenously as
   prescribed.
   e. Monitor intake and output and daily
   weight.
   f. Monitor for a urinary output of
   30 to 50 mL/hr to ensure adequate
   renal function.
   g. Maintain the client in a semi-
   Fowler’s position.
   h. If a nephrostomy tube is in
   place, do not irrigate (unless
   specifically prescribed) or manipulate
   the tube.

XXIII. Epididymitis
A. Description
   1. Acute or chronic inflammation of the epididymis that
   occurs as a result of a UTI, STI, prostatitis, or long-
   term use of a bladder catheter
   2. The infective organism travels upward through the
   urethra and ejaculatory duct and along the vas
dererens to the epididymis.
B. Assessment
1. Scrotal and groin pain
2. Swelling in the scrotum and groin
3. Pus and bacteria in the urine
4. Fever and chills
5. Abscess development

C. Interventions
1. Encourage fluid intake.
2. Encourage bed rest with the scrotum elevated to prevent traction on the spermatic cord, facilitate drainage, and relieve pain.
3. Instruct the client in the intermittent application of cold compresses to the scrotum.
4. Instruct the client in the use of tub or sitz baths.
5. Instruct the client in the administration of antibiotics for self and sexual partner if the cause is chlamydial or gonorrheal infection.
6. Instruct the client to avoid lifting, straining, and sexual contact until the infection subsides.
7. Instruct the client to limit the force of the urine stream, because organisms can be forced into the vas deferens and epididymis from strain or pressure during voiding.
8. Teach the client that condom use can help prevent urethritis and epididymitis.
9. Teach the client measures to prevent UTI or STI recurrence.

XXIV. Prostatitis
A. Description
1. Inflammation of the prostate gland commonly caused by an infectious agent; may be acute or chronic.
2. The bacterial type occurs as a result of the organism reaching the prostate via the urethra, bladder, bloodstream, or lymphatic channels.
3. The abacterial type usually occurs following a viral illness or a decrease in sexual activity.

B. Assessment
1. Bacterial prostatitis
   a. Client becomes acutely ill.
   b. Fever and chills
   c. Frequency and urgency of urination; dysuria
   d. Perineal and low back pain
   e. Urethral discharge
   f. Prostate is tender, indurated, and warm to the touch.
   g. Urethral discharge on palpation of prostate
   h. WBCs are found in prostatic secretions.
1. Urine culture is usually positive for gram-negative bacteria, especially after prostate massage.

2. Abacterial prostatitis (most common form of chronic prostatitis)
   a. Backache
   b. Dysuria
   c. Perineal pain
   d. Frequency
   e. Hematuria
   f. Irregularly enlarged, firm, and tender prostate

C. Interventions
1. Encourage adequate fluid intake.
2. Instruct the client in the use of tub or sitz baths to promote comfort.
3. Administer antibiotics, analgesics, antispasmodics, and stool softeners as prescribed.
4. Inform the client of activities to drain the prostate, such as intercourse, masturbation, and prostatic massage.
5. Instruct the client to avoid spicy foods, coffee, alcohol, prolonged automobile rides, and sexual intercourse during an acute inflammation.

XXV. Benign Prostatic Hypertrophy (Hyperplasia)

A. Description
1. Benign prostatic hypertrophy (benign prostatic hyperplasia; BPH) is a slow enlargement of the prostate gland, with hypertrophy and hyperplasia of normal tissue.
2. Enlargement compresses the urethra, resulting in partial or complete obstruction.
3. Usually occurs in men older than 50 years

B. Assessment
1. Diminished size and force of urinary stream (early sign of BPH)
2. Urinary urgency and frequency
3. Nocturia
4. Inability to start (hesitancy) or continue a urinary stream
5. Feelings of incomplete bladder emptying
6. Postvoid dribbling from overflow incontinence (later sign)
7. Urinary retention and bladder distention
8. Hematuria
9. Urinary stasis and UTIs
10. Dysuria and bladder pain

1866
C. Interventions
1. Encourage fluid intake of up to 2000 to 3000 mL/day unless contraindicated.
2. Prepare for urinary catheterization to drain the bladder and prevent distention.
3. Avoid administering medications that cause urinary retention, such as anticholinergics, antihistamines, decongestants, and antidepressants.
4. Administer medications as prescribed to shrink the prostate gland and improve urine flow.
5. Administer medications as prescribed to relax prostatic smooth muscle and improve urine flow.
6. Instruct the client to decrease intake of caffeine and artificial sweeteners and limit spicy or acidic foods.
7. Instruct the client to follow a timed voiding schedule.
8. Prepare the client for surgery or invasive procedures as prescribed (Figs. 54-7 and 54-8).

D. Surgical interventions and postoperative care (see Chapter 44)

XXVI. Bladder Cancer: Refer to Chapter 44
XXVII. Bladder Trauma

A. Description
1. Occurs following a blunt or penetrating injury to the lower abdomen
2. Blunt trauma causes compression of the abdominal wall and bladder.
3. Penetrating wounds occur as a result of a stabbing, gunshot wound, or other objects piercing the abdominal wall.
4. A fractured pelvis that causes bone fragments to puncture the bladder is a common cause of bladder trauma.

B. Assessment
1. **Anuria**
2. Hematuria
3. Pain below the level of the umbilicus; can radiate to the shoulders
4. Nausea and vomiting

C. Interventions
1. Monitor vital signs.
2. Monitor for hematuria, bleeding, and signs of shock.
3. Maintain bed rest.
4. If blood is seen at the meatus, avoid urinary catheterization until a retrograde ureterogram can be obtained.
5. Prepare the client for insertion of a suprapubic catheter to aid in urinary drainage if prescribed.
6. Prepare the client for surgical repair of the laceration if indicated.

**Box 54-1**

**Risk Factors Associated with Renal Problems**

- Chemical or environmental toxin exposure
- Contact sports
- Diabetes mellitus
- Family history of renal disease
- Frequent urinary tract infections
- Heart failure
- High-sodium diet
- Hypertension
- Medications
- Polycystic kidney disease
- Trauma
- Urolithiasis or nephrolithiasis

**Box 54-2**

**Normal Renal Function Values**

- Blood urea nitrogen (BUN) level, 10 to 20 mg/dL (3.6 to 7.1 mmol/L)
- Serum creatinine level, 0.6 to 1.2 mg/dL (53 to 106 mcmol/L) for males and 0.5 to 1.1 mg/dL (44 to 97 mcmol/L) for females
- BUN/creatinine ratio, 6 to 25

**Table 54-1**

**Box 54-3**

**Potentially Nephrotoxic Substances**

**Medications**

**Antibiotics: Anti-infectives**

- Amphotericin B
- Methicillin
- Polymyxin B
- Rifampin
- Sulfonamides
- Tetracycline hydrochloride
- Vancomycin

**Aminoglycoside Antibiotics**

- Gentamicin
- Kanamycin
- Neomycin
- Tobramycin

**Antineoplastics**

- Cisplatin
- Cyclophosphamide
- Methotrexate

**Nonsteroidal Anti-inflammatory Drugs (NSAIDs)**

- Celecoxib
- Flurbiprofen
- Ibuprofen
- Indomethacin
- Ketorolac
- Meclofenamate
- Meloxicam
- Nabumetone
- Naproxen
• Oxaprozin
• Rofecoxib
• Tolmetin

Other Medications

• Acetaminophen
• Captopril
• Cyclosporine
• Fluorinate anesthetics
• **d**-Penicillamine
• Phenazopyridine hydrochloride
• Quinine

Other Substances

• Organic solvents
• Carbon tetrachloride
• Ethylene glycol

Nonpharmacological Chemical Agents

• Radiographic contrast dye
• Pesticides
• Fungicides
• Myoglobin (from breakdown of skeletal muscle)

Heavy Metals and Ions

• Arsenic
• Bismuth
• Copper sulfate
• Gold salts
• Lead
• Mercuric chloride

Acute Kidney Injury: Phases and Laboratory Findings

Onset

- Begins with precipitating event

Oliguric Phase

- Elevated blood urea nitrogen (BUN) and serum creatinine levels
- Decreased urine specific gravity (prerenal causes) or normal (intrarenal causes)
- Decreased glomerular filtration rate (GFR) and creatinine clearance
- Hyperkalemia
- Normal or decreased serum sodium level
- Hypovolemia
- Hypocalcemia
- Hyperphosphatemia

Diuretic Phase

- Gradual decline in BUN and serum creatinine levels, but still elevated
- Continued low creatinine clearance with improving GFR
- Hypokalemia
- Hyponatremia
- Hypovolemia

Recovery Phase (Convalescent)

- Increased GFR
- Stabilization or continual decline in BUN and serum creatinine levels toward normal
- Complete recovery (may take 1 to 2 years)

Table 54-2

CKD, Chronic kidney disease; ESRD, end-stage renal disease; GFR, glomerular filtration rate.

Data from Ignatavicius D, Workman ML: *Medical-surgical nursing: patient-centered*
**Box 54-5**

**Key Features of Chronic Kidney Disease**

**Neurological Manifestations**

- Asterixis
- Ataxia (alteration in gait)
- Inability to concentrate or decreased attention span
- Lethargy and daytime drowsiness
- Myoclonus
- Paresthesias
- Seizures
- Slurred speech
- Tremors, twitching, or jerky movements
- Coma

**Cardiovascular Manifestations**

- Hypertension
- Heart failure
- Peripheral edema
- Cardiomyopathy
- Pericardial effusion
- Pericardial friction rub
- Uremic pericarditis
- Cardiac tamponade

**Respiratory Manifestations**

- Crackles
- Deep sighing, yawning
- Depressed cough reflex
- Shortness of breath
- Tachypnea
- Kussmaul's respirations
- Pleural effusion
- Pulmonary edema
- Uremic halitosis
- Uremic pneumonia

**Hematological Manifestations**

- Abnormal bleeding and bruising
- Anemia

**Gastrointestinal Manifestations**

- Anorexia, nausea, vomiting
- Changes in taste acuity and sensation
- Constipation
- Diarrhea
- Metallic taste in the mouth
- Stomatitis
- Uremic colitis (diarrhea)
- Uremic fetor
- Uremic gastritis (possible gastrointestinal bleeding)

**Urinary Manifestations**

- Polyuria, nocturia (early)
- Proteinuria
- Diluted, straw-colored appearance
- Hematuria
- Oliguria, anuria (later)

**Integumentary Manifestations**

- Decreased skin turgor
- Dry skin
- Yellow-gray pallor
- Ecchymosis
- Pruritus
- Purpura
- Soft tissue calcifications
- Uremic frost (late, premorbid)

**Musculoskeletal Manifestations**

- Bone pain
• Muscle weakness and cramping
• Pathological fractures
• Renal osteodystrophy

**Reproductive Manifestations**

• Decreased fertility
• Decreased libido
• Impotence
• Infrequent or absent menses

**Box 54-6**

**Special Problems in Kidney Disease**

• Activity intolerance and insomnia
• Anemia
• Gastrointestinal bleeding
• Hyperkalemia
• Hypermagnesemia
• Hyperphosphatemia
• Hypertension
• Hypervolemia
• Hypocalcemia
• Hypovolemia
• Infection
• Metabolic acidosis
• Muscle cramps
• Neurological changes
• Ocular irritation
• Potential for injury
• Pruritus
• Psychosocial problems
FIG. 54-1 Cardiac rhythm changes with hyperkalemia.
Fig. 54-2 Vascular access for hemodialysis. A, External shunt. B, Internal arteriovenous fistula. C, Internal arteriovenous graft. D, A hemodialysis graft while connected to a hemodialysis machine. (D, From Lewis et al., 2011.)

Box 54-7

Complications of Hemodialysis

- Air embolus
- Disequilibrium syndrome
- Electrolyte alterations
- Encephalopathy
- Hemorrhage
- Hepatitis
- Hypotension
- Sepsis
- Shock
Box 54-8

Types of Automated Peritoneal Dialysis

Continuous Cycling Peritoneal Dialysis

- Dialysis requires a peritoneal cycling machine.
- Dialysis usually consists of 3 cycles done at night and 1 cycle with an 8-hour dwell done in the morning.
- The sterile catheter system is opened only for the on-and-off procedures, which reduces the risk of infection.
- The client does not need to do exchanges during the day.

Intermittent Peritoneal Dialysis

- Dialysis requires a peritoneal cycling machine.
- Dialysis is not a continuous procedure.
- Dialysis is performed for 10 to 14 hours, 3 or 4 times a week.

Nightly Peritoneal Dialysis

- Dialysis requires a cycling machine.
- Dialysis is performed for 8 to 12 hours each night, with no daytime exchanges or dwells.
**Box 54-9**

**Client Instructions Following Kidney Transplantation**

- Avoid prolonged periods of sitting.
- Monitor intake and output.
- Recognize the signs and symptoms of infection and rejection.
- Use medications as prescribed, and maintain immunosuppressive therapy for life.
- Avoid contact sports.
- Avoid exposure to persons with infections.
- Know the signs and symptoms that require the need to contact the primary health care provider or nephrologist.
- Ensure follow-up care.

**Box 54-10**

**Clinical Signs of Renal Transplant (Graft) Rejection**

- Temperature higher than 100°F (37.8°C)
- Pain or tenderness over the grafted kidney
- 2- to 3-lb (0.9 to 1.4 kg) weight gain in 24 hours
- Edema
- Hypertension
- Malaise
- Elevated blood urea nitrogen and serum creatinine levels
- Decreased creatinine clearance
- Elevated white blood cell count
- Rejection indicated by ultrasound or biopsy

**Box 54-11**

**Causes of Cystitis**

- Allergens or irritants, such as soaps, sprays, bubble bath, perfumed sanitary napkins
- Bladder distention
- Calculus
- Hormonal changes, influencing alterations in vaginal flora
- Indwelling urinary catheters
- Invasive urinary tract procedures
- Loss of bactericidal properties of prostatic secretions in the male
- Microorganisms
- Poor-fitting vaginal diaphragms
- Sexual intercourse
- Synthetic underwear and pantyhose
- Urinary stasis
- Use of spermicides
- Wet bathing suits

**Box 54-12**

**Client Instructions for Prevention of Cystitis**

- Use good perineal care, wiping front to back.
- Avoid bubble baths, tub baths, and vaginal deodorants or sprays.
- Void every 2 to 3 hours.
- Wear cotton pants and avoid wearing tight clothes or pantyhose with slacks.
- Avoid sitting in a wet bathing suit for prolonged periods of time.
- If pregnant, void every 2 hours.
- If menopausal, use estrogen vaginal creams to restore pH.
- Use water-soluble lubricants for intercourse, especially after menopause.
Void and drink a glass of water after intercourse.

FIG. 54-5 Hydronephrosis and hydroureter.

Box 54-13

Nutritional Therapy for Calculi

*Note:* Depending on the type of calculi, the diet is modified to decrease foods that are high in the substance that is the cause of the calculi.

**Purine**

- *High:* Sardines, herring, mussels, liver, kidney, goose, venison, meat soups, sweetbreads
- *Moderate:* Chicken, salmon, crab, veal, mutton, bacon, pork, beef, ham
Calcium

- **High:** Milk, cheese, ice cream, yogurt, sauces containing milk; all beans (except green beans), lentils; fish with fine bones (e.g., sardines, kippers, herring, salmon); dried fruits, nuts; cocoa powder, chocolate, cocoa

Oxalate

- **High:** Dark roughage, spinach, rhubarb, asparagus, cabbage, tomatoes, beets, nuts, celery, parsley, runner beans; chocolate, cocoa, instant coffee, cocoa powder, tea; Worcestershire sauce

* Uric acid is a waste product from purine in food.

![FIG. 54-6 Treatment options for ureteral stones. ESWL, Extracorporeal shock wave lithotripsy.](image-url)
FIG. 54-7  Transurethral resection of the prostate.
FIG. 54-8  Surgical approaches for prostatectomy.  

A, Retropubic approach involves a low abdominal incision.  

B, Perineal approach involves an incision between the scrotum and anus.  

C, Suprapubic approach involves a midline abdominal incision.
**Practice Questions**

641. A client with acute kidney injury has a serum potassium level of 7.0 mEq/L (7.0 mmol/L). The nurse should plan which actions as a priority? Select all that apply.

- [ ] 1. Place the client on a cardiac monitor.
- [ ] 2. Notify the primary health care provider (PHCP).
- [ ] 3. Put the client on NPO (nothing by mouth) status except for ice chips.
- [ ] 4. Review the client’s medications to determine whether any contain or retain potassium.
- [ ] 5. Allow an extra 500 mL of intravenous fluid intake to dilute the electrolyte concentration.

642. A client with chronic kidney disease being hemodialyzed suddenly becomes short of breath and complains of chest pain. The client is tachycardic, pale, and anxious, and the nurse suspects air embolism. What are the priority nursing actions? Select all that apply.

- [ ] 1. Administer oxygen to the client.
- [ ] 2. Continue dialysis at a slower rate after checking the lines for air.
- [ ] 3. Notify the primary health care provider (PHCP) and Rapid Response Team.
- [ ] 4. Stop dialysis, and turn the client on the left side with head lower than feet.
- [ ] 5. Bolus the client with 500 mL of normal saline to break up the air embolus.

643. A client arrives at the emergency department with complaints of low abdominal pain and hematuria. The client is afebrile. The nurse next assesses the client to determine a history of which condition?

- [ ] 1. Pyelonephritis
- [ ] 2. Glomerulonephritis
- [ ] 3. Trauma to the bladder or abdomen
- [ ] 4. Renal cancer in the client’s family

644. The nurse discusses plans for future treatment options with a client with symptomatic polycystic kidney disease. Which treatment should be included in this discussion? Select all that apply.

- [ ] 1. Hemodialysis
- [ ] 2. Peritoneal dialysis
3. Kidney transplant
4. Bilateral nephrectomy
5. Intense immunosuppression therapy

645. A client is admitted to the emergency department following a fall from a horse, and the primary health care provider (PHCP) prescribes insertion of a urinary catheter. While preparing for the procedure, the nurse notes blood at the urinary meatus. The nurse should take which action?
   1. Notify the PHCP before performing the catheterization.
   2. Use a small-sized catheter and an anesthetic gel as a lubricant.
   3. Administer parenteral pain medication before inserting the catheter.
   4. Clean the meatus with soap and water before opening the catheterization kit.

646. The nurse is assessing the patency of a client’s left arm arteriovenous fistula prior to initiating hemodialysis. Which finding indicates that the fistula is patent?
   1. Palpation of a thrill over the fistula.
   2. Presence of a radial pulse in the left wrist.
   3. Visualization of enlarged blood vessels at the fistula site.
   4. Capillary refill less than 3 seconds in the nailbeds of the fingers on the left hand.

647. A male client has a tentative diagnosis of urethritis. The nurse should assess the client for which manifestation of the disorder?
   1. Hematuria and pyuria
   2. Dysuria and proteinuria
   3. Hematuria and urgency
   4. Dysuria and penile discharge

648. The nurse is assessing a client with epididymitis. The nurse anticipates which findings on physical examination?
   1. Fever, diarrhea, groin pain, and ecchymosis
   2. Nausea, painful scrotal edema, and ecchymosis
   3. Fever, nausea, vomiting, and painful scrotal edema
   4. Diarrhea, groin pain, testicular torsion, and scrotal edema

649. A client complains of fever, perineal pain, and urinary urgency, frequency, and dysuria. To assess whether the client’s problem is related to bacterial prostatitis, the nurse reviews the results of the prostate examination for which characteristic of this disorder?
   1. Soft and swollen prostate gland
   2. Swollen and boggy prostate gland
   3. Tender and edematous prostate gland
   4. Tender, indurated prostate gland that is warm to the touch

650. The nurse is collecting data from a client. Which symptom described by the client is characteristic of an early symptom of benign prostatic hyperplasia?
   1. Nocturia
   2. Scrotal edema
   3. Occasional constipation
4. Decreased force in the stream of urine

651. The nurse monitoring a client receiving peritoneal dialysis notes that the client’s outflow is less than the inflow. Which actions should the nurse take? Select all that apply.

- Check the level of the drainage bag.
- Reposition the client to her or his side.
- Place the client in good body alignment.
- Check the peritoneal dialysis system for kinks.
- Contact the primary health care provider (PHCP).
- Increase the flow rate of the peritoneal dialysis solution.

652. A hemodialysis client with a left arm fistula is at risk for arterial steal syndrome. The nurse should assess for which manifestations of this complication?

- Warmth, redness, and pain in the left hand
- Ecchymosis and audible bruit over the fistula
- Edema and reddish discoloration of the left arm
- Pallor, diminished pulse, and pain in the left hand

653. The nurse is reviewing a client’s record and notes that the primary health care provider has documented that the client has chronic kidney disease. On review of the laboratory results, the nurse most likely would expect to note which finding?

- Elevated creatinine level
- Decreased hemoglobin level
- Decreased red blood cell count
- Increased number of white blood cells in the urine

654. A client with chronic kidney disease returns to the nursing unit following a hemodialysis treatment. On assessment, the nurse notes that the client’s temperature is 38.5°C (101.2°F). Which nursing action is most appropriate?

- Encourage fluid intake.
- Continue to monitor vital signs.
- Notify the primary health care provider.
- Monitor the site of the shunt for infection.

655. The nurse is performing an assessment on a client who has returned from the dialysis unit following hemodialysis. The client is complaining of headache and nausea and is extremely restless. Which is the priority nursing action?

- Monitor the client.
- Elevate the head of the bed.
- Assess the fistula site and dressing.
- Notify the primary health care provider (PHCP).

656. A client with severe back pain and hematuria is found to have hydronephrosis due to urolithiasis. The nurse anticipates which treatment will be done to relieve the obstruction? Select all that apply.

- Peritoneal dialysis
2. Analysis of the urinary stone
3. Intravenous opioid analgesics
4. Insertion of a nephrostomy tube
5. Placement of a ureteral stent with ureteroscopy

657. The nurse is instructing a client with diabetes mellitus about peritoneal dialysis. The nurse tells the client that it is important to maintain the prescribed dwell time for the dialysis because of the risk of which complication?
   1. Peritonitis
   2. Hyperglycemia
   3. Hyperphosphatemia
   4. Disequilibrium syndrome

658. A week after kidney transplantation, a client develops a temperature of 101°F (38.3°C), the blood pressure is elevated, and there is tenderness over the transplanted kidney. The serum creatinine is rising and urine output is decreased. The x-ray indicates that the transplanted kidney is enlarged. Based on these assessment findings, the nurse anticipates which treatment?
   1. Antibiotic therapy
   2. Peritoneal dialysis
   3. Removal of the transplanted kidney
   4. Increased immunosuppression therapy

659. A client is admitted to the hospital with a diagnosis of benign prostatic hyperplasia, and a transurethral resection of the prostate is performed. Four hours after surgery, the nurse takes the client’s vital signs and empties the urinary drainage bag. Which assessment finding indicates the need to notify the primary health care provider (PHCP)?
   1. Red, bloody urine
   2. Pain rated as 2 on a 0 to 10 pain scale
   3. Urinary output of 200 mL higher than intake
   4. Blood pressure, 100/50 mm Hg; pulse, 130 beats per minute

660. The client newly diagnosed with chronic kidney disease recently has begun hemodialysis. Knowing that the client is at risk for disequilibrium syndrome, the nurse should assess the client during dialysis for which associated manifestations?
   1. Hypertension, tachycardia, and fever
   2. Hypotension, bradycardia, and hypothermia
   3. Restlessness, irritability, and generalized weakness
   4. Headache, deteriorating level of consciousness, and twitching

**Answers**

641. **Answer:** 1, 2, 4

**Rationale:** The normal potassium level is 3.5 to 5.0 mEq/L (3.5 to 5.0 mmol/L). A
potassium level of 7.0 is elevated. The client with hyperkalemia is at risk of developing cardiac dysrhythmias and cardiac arrest. Because of this, the client should be placed on a cardiac monitor. The nurse should notify the PHCP and also review medications to determine whether any contain potassium or are potassium retaining. The client does not need to be put on NPO status. Fluid intake is not increased because it contributes to fluid overload and would not affect the serum potassium level significantly.

**Test-Taking Strategy:** Note the **strategic word**, **priority**. First, note that the potassium level is significantly elevated to select options 1 and 4. Also, use the **ABCs** — **airway, breathing, and circulation** — to select option 2.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Planning

**Content Area:** Adult Health: Renal and Urinary

**Health Problem:** Adult Health: Renal and Urinary: Acute kidney injury

**Priority Concepts:** Clinical Judgment; Fluids and Electrolytes

642. **Answer:** 1, 3, 4

**Rationale:** If the client experiences air embolus during hemodialysis, the nurse should terminate dialysis immediately, position the client so the air embolus is in the right side of the heart, notify the PHCP and Rapid Response Team, and administer oxygen as needed. Slowing the dialysis treatment or giving an intravenous bolus will not correct the air embolism or prevent complications.

**Test-Taking Strategy:** Note the **strategic word**, **priority**. Recall that air embolism is an emergency situation that affects the cardiopulmonary system suddenly and profoundly. Select the options that deal with the problem, supply oxygen, and get needed assistance.

**Level of Cognitive Ability:** Synthesizing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Complex Care: Emergency Situations/Management

**Health Problem:** Adult Health: Renal and Urinary: Chronic kidney disease

**Priority Concepts:** Clinical Judgment; Gas Exchange

643. **Answer:** 3

**Rationale:** Bladder trauma or injury should be considered or suspected in the client with low abdominal pain and hematuria. Glomerulonephritis and pyelonephritis would be accompanied by fever and are thus not applicable to the client described in this question. Renal cancer would not cause pain that is felt in the low abdomen; rather, the pain would be in the flank area.

**Test-Taking Strategy:** Note the **strategic word**, **next**. Eliminate options 1 and 2 because they are **comparable or alike**, knowing that any inflammatory disease or infection is accompanied by fever. Because this client is afebrile, these are not
possible options. Use knowledge of anatomy and pain assessment to select the correct option. Pain from renal cancer is a later finding and is localized in the flank area.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity

**Content Area:** Adult Health: Renal and Urinary  
**Health Problem:** N/A  
**Priority Concepts:** Clinical Judgment; Pain  
**Reference:** Lewis et al. (2017), p. 1050.

644. **Answer:** 1, 3, 4

**Rationale:** Polycystic kidney disease is a genetic familial disease in which the kidneys enlarge with cysts that rupture and scar the kidney, eventually resulting in end-stage renal disease. Treatment options include hemodialysis or kidney transplant. Clients usually undergo bilateral nephrectomy to remove the large, painful, cyst-filled kidneys. Peritoneal dialysis is not a treatment option due to the cysts. The condition does not respond to immunosuppression.

**Test-Taking Strategy:** Focus on the subject, treatment options for polycystic kidney disease. Recall that the condition results in end-stage renal disease. This will direct you to the correct options.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Adult Health: Renal and Urinary  
**Health Problem:** Adult Health: Renal and Urinary: Hereditary diseases  
**Priority Concepts:** Clinical Judgment; Client Education  

645. **Answer:** 1

**Rationale:** The presence of blood at the urinary meatus may indicate urethral trauma or disruption. The nurse notifies the PHCP, knowing that the client should not be catheterized until the cause of the bleeding is determined by diagnostic testing. The other options include performing the catheterization procedure and therefore are incorrect.

**Test-Taking Strategy:** Focus on the subject, the complications associated with a traumatic fall. Noting the words blood at the urinary meatus suggests more extensive internal trauma that could be further aggravated by the catheterization.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Adult Health: Renal and Urinary  
**Health Problem:** N/A  
**Priority Concepts:** Clinical Judgment; Safety  
Rationale: The nurse assesses the patency of the fistula by palpating for the presence of a thrill or auscultating for a bruit. The presence of a thrill and bruit indicate patency of the fistula. Enlarged visible blood vessels at the fistula site are a normal observation but are not indicative of fistula patency. Although the presence of a radial pulse in the left wrist and capillary refill less than 3 seconds in the nailbeds of the fingers on the left hand indicate adequate circulation to the hand, they do not assess fistula patency.

Test-Taking Strategy: Eliminate options 2 and 4 first because they are comparable or alike, and assess for adequate circulation in the distal portion of the extremity (not the fistula). Enlarged blood vessels occur when the fistula is created. Select option 1, because a thrill indicates blood flow and patency of the fistula.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Renal and Urinary
Health Problem: Adult Health: Renal and Urinary: Chronic kidney disease
Priority Concepts: Clinical Judgment; Clotting

Rationale: Urethritis in the male client often results from chlamydial infection and is characterized by dysuria, which is accompanied by a clear to mucopurulent discharge. Because this disorder often coexists with gonorrhea, diagnostic tests are done for both and include culture and rapid assays. Hematuria is not associated with urethritis. Proteinuria is associated with kidney dysfunction.

Test-Taking Strategy: Focus on the subject, manifestations of urethritis. Recalling that urethritis generally is accompanied by dysuria in the male client will assist you in eliminating options 1 and 3. Knowing that the problem originates in the urethra, not the kidneys, will assist you in eliminating option 2, because proteinuria indicates a problem with kidney function.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Renal and Urinary
Health Problem: Adult Health: Renal and Urinary: Inflammation/Infections
Priority Concepts: Infection; Sexuality

Rationale: Typical signs and symptoms of epididymitis include scrotal pain and edema, which often are accompanied by fever, nausea and vomiting, and chills. Epididymitis most often is caused by infection, although sometimes it can be caused by trauma. The remaining options do not present all of the accurate manifestations.
**Test-Taking Strategy:** Any disorder that ends in *-itis* results from inflammation or infection. Therefore, an expected finding would be elevated temperature. With this in mind, eliminate options 2 and 4 because they are **comparable or alike** and do not contain fever as part of the option. Knowing that ecchymosis results from bleeding, which is not part of this clinical picture, directs you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Renal and Urinary

**Health Problem:** Adult Health: Renal and Urinary: Inflammation/Infections

**Priority Concepts:** Infection; Inflammation

**Reference:** Lewis et al. (2017), p. 1284.

649. **Answer:** 4

**Rationale:** The client with bacterial prostatitis has a swollen and tender prostate gland that is also warm to the touch, firm, and indurated. Systemic symptoms include fever with chills, perineal and low back pain, and signs of urinary tract infection, which often accompany the disorder.

**Test-Taking Strategy:** Focus on the subject, manifestations of bacterial prostatitis. Begin to answer this question by reasoning that inflammation of the prostate gland would cause the area to be tender. This would allow you to eliminate options 1 and 2. Recalling that inflammation is accompanied by local warmth will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Content Area:** Adult Health: Renal and Urinary

**Health Problem:** Adult Health: Renal and Urinary: Inflammation/Infections

**Priority Concepts:** Infection; Inflammation

**Reference:** Lewis et al. (2017), p. 1282-1283.

650. **Answer:** 4

**Rationale:** Decreased force in the stream of urine is an early symptom of benign prostatic hyperplasia. The stream later becomes weak and dribbling. The client then may develop hematuria, frequency, urgency, urge incontinence, and nocturia. If untreated, complete obstruction and urinary retention can occur. Constipation or scrotal edema is not associated with benign prostatic hyperplasia.

**Test-Taking Strategy:** Note the strategic word, *early.* Also, if you know that benign prostatic hyperplasia can lead to urinary obstruction, look for the option that identifies the least severe symptom.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Renal and Urinary

**Health Problem:** Adult Health: Renal and Urinary: Obstructive problems
Priority Concepts: Elimination; Inflammation

651. Answer: 1, 2, 3, 4

Rationale: If outflow drainage is inadequate, the nurse attempts to stimulate outflow by changing the client’s position. Turning the client to the side or making sure that the client is in good body alignment may assist with outflow drainage. The drainage bag needs to be lower than the client’s abdomen to enhance gravity drainage. The connecting tubing and peritoneal dialysis system are also checked for kinks or twisting, and the clamps on the system are checked to ensure that they are open. There is no reason to contact the PHCP. Increasing the flow rate should not be done and also is not associated with the amount of outflow solution.

Test-Taking Strategy: Focus on the subject, outflow is less than inflow, and use the principles related to gravity flow and preventing obstruction to flow to answer this question. This will assist in determining the correct interventions.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Adult Health: Renal and Urinary
Health Problem: Adult Health: Renal and Urinary: Chronic kidney disease
Priority Concepts: Clinical Judgment; Elimination

652. Answer: 4

Rationale: Steal syndrome results from vascular insufficiency after creation of a fistula. The client exhibits pallor and a diminished pulse distal to the fistula. The client also complains of pain distal to the fistula, caused by tissue ischemia. Warmth and redness probably would characterize a problem with infection. Ecchymosis and a bruit are normal findings for a fistula.

Test-Taking Strategy: Focus on the subject, arterial steal syndrome. Eliminate signs associated with infection or normal fistula findings. Recalling that steal syndrome results from vascular insufficiency after creation of a fistula will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Renal and Urinary
Health Problem: Adult Health: Renal and Urinary: Chronic kidney disease
Priority Concepts: Clinical Judgment; Perfusion

653. Answer: 1

Rationale: The creatinine level is the most specific laboratory test to determine renal function. The creatinine level increases when at least 50% of renal function is
lost. A decreased hemoglobin level and red blood cell count are associated with anemia or blood loss and not specifically with decreased renal function. Increased white blood cells in the urine are noted with urinary tract infection.

**Test-Taking Strategy:** Note the **strategic words**, *most likely*. Recalling the relationship between the creatinine level and renal function will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Renal and Urinary

**Health Problem:** Adult Health: Renal and Urinary: Chronic kidney disease

**Priority Concepts:** Cellular Regulation; Elimination

654. **Answer:** 3

**Rationale:** A temperature of 101.2° F (38.5° C) is significantly elevated and may indicate infection. The nurse should notify the primary health care provider (PHCP). Dialysis clients cannot have fluid intake encouraged. Vital signs and the shunt site should be monitored, but the PHCP should be notified first.

**Test-Taking Strategy:** Note the **strategic words**, *most appropriate*. Focus on the data in the question. Note the temperature elevation. This warrants notification of the PHCP, who may prescribe diagnostic tests or medications.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Adult Health: Renal and Urinary

**Health Problem:** Adult Health: Renal and Urinary: Chronic kidney disease

**Priority Concepts:** Clinical Judgment; Elimination

655. **Answer:** 4

**Rationale:** Disequilibrium syndrome may be caused by rapid removal of solutes from the body during hemodialysis. These changes can cause cerebral edema that leads to increased intracranial pressure. The client is exhibiting early signs and symptoms of disequilibrium syndrome, and appropriate treatments with anticonvulsive medications and barbiturates may be necessary to prevent a life-threatening situation. The PHCP must be notified. Monitoring the client, elevating the head of the bed, and assessing the fistula site are correct actions, but the priority action is to notify the PHCP.

**Test-Taking Strategy:** Note the **strategic word**, *priority*, and focus on the client’s signs and symptoms. **Determine if an abnormality exists.** Recalling the serious complications associated with hemodialysis such as disequilibrium syndrome will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity
**Integrated Process**: Nursing Process—Implementation

**Content Area**: Adult Health: Renal and Urinary

**Health Problem**: Adult Health: Renal and Urinary: Chronic kidney disease

**Priority Concepts**: Clinical Judgment; Intracranial Regulation

656. **Answer**: 4, 5

**Rationale**: Urolithiasis is the condition that occurs when a stone forms in the urinary system. Hydronephrosis develops when the stone has blocked the ureter and urine backs up and dilates and damages the kidney. Priority treatment is to allow the urine to drain and relieve the obstruction in the ureter. This is accomplished by placement of a percutaneous nephrostomy tube to drain urine from the kidney and placement of a ureteral stent to keep the ureter open. Peritoneal dialysis is not needed, since the kidney is functioning. Stone analysis will be done later when the stone has been retrieved and analyzed. Opioid analgesics are necessary for pain relief but do not treat the obstruction.

**Test-Taking Strategy**: Focus on the subject, treatment to relieve the obstruction. Think about what each option will accomplish. Eliminate the options that do not address the obstruction.

**Level of Cognitive Ability**: Analyzing

**Client Needs**: Physiological Integrity

**Integrated Process**: Nursing Process—Analysis

**Content Area**: Adult Health: Renal and Urinary

**Health Problem**: Adult Health: Renal and Urinary: Obstructive problems

**Priority Concepts**: Clinical Judgment; Elimination

657. **Answer**: 2

**Rationale**: An extended dwell time increases the risk of hyperglycemia in the client with diabetes mellitus as a result of absorption of glucose from the dialysate and electrolyte changes. Diabetic clients may require extra insulin when receiving peritoneal dialysis. Peritonitis is a risk associated with breaks in aseptic technique. Hyperphosphatemia is an electrolyte imbalance that occurs with renal dysfunction. Disequilibrium syndrome is a complication associated with hemodialysis.

**Test-Taking Strategy**: Focus on the subject, a complication associated with an extended dwell time. Noting the client’s diagnosis and recalling that the dialysate solution contains glucose will direct you to the correct option.

**Level of Cognitive Ability**: Applying

**Client Needs**: Physiological Integrity

**Integrated Process**: Teaching and Learning

**Content Area**: Adult Health: Renal and Urinary

**Health Problem**: Adult Health: Renal and Urinary: Chronic kidney disease

**Priority Concepts**: Elimination; Glucose Regulation

**Rationale:** Acute rejection most often occurs within 1 week after transplantation but can occur any time post-transplantation. Clinical manifestations include fever, malaise, elevated white blood cell count, acute hypertension, graft tenderness, and manifestations of deteriorating renal function. Treatment consists of increasing immunosuppressive therapy. Antibiotics are used to treat infection. Peritoneal dialysis cannot be used with a newly transplanted kidney due to the recent surgery. Removal of the transplanted kidney is indicated with hyperacute rejection, which occurs within 48 hours of the transplant surgery.

**Test-Taking Strategy:** Note the words *A week after kidney transplantation*. Focus on the **data in the question** and the time frame and symptoms, which describe acute rejection. Recall the treatment for **acute rejection** to direct you to the correct option.

**Level of Cognitive Ability:** Synthesizing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Analysis

**Content Area:** Adult Health: Renal and Urinary

**Health Problem:** Adult Health: Immune: Transplantation

**Priority Concepts:** Elimination; Immunity

---

**Rationale:** Frank bleeding (arterial or venous) may occur during the first day after surgery. Some hematuria is usual for several days after surgery. A urinary output of 200 mL more than intake is adequate. A client pain rating of 2 on a 0 to 10 scale indicates adequate pain control. A rapid pulse with a low blood pressure is a potential sign of excessive blood loss. The PHCP should be notified.

**Test-Taking Strategy:** Focus on the **subject**, the need to notify the PHCP, and determine if an abnormality exists. Think about the expected findings following this procedure and note that the vital signs are not within the normal range and could indicate excessive blood loss.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Analysis

**Content Area:** Adult Health: Renal and Urinary

**Health Problem:** Adult Health: Renal and Urinary: Obstructive problems

**Priority Concepts:** Collaboration; Clotting

**Reference:** Lewis et al. (2017), pp. 1274-1275.

---

**Rationale:** Disequilibrium syndrome is characterized by headache, mental confusion, decreasing level of consciousness, nausea, vomiting, twitching, and possible seizure activity. Disequilibrium syndrome is caused by rapid removal of solutes from the body during hemodialysis. At the same time, the blood–brain barrier interferes with the efficient removal of wastes from brain tissue. As a result,
water goes into cerebral cells because of the osmotic gradient, causing increased intracranial pressure and onset of symptoms. The syndrome most often occurs in clients who are new to dialysis and is prevented by dialyzing for shorter times or at reduced blood flow rates. Tachycardia and fever are associated with infection. Generalized weakness is associated with low blood pressure and anemia. Restlessness and irritability are not associated with disequilibrium syndrome.

**Test-Taking Strategy:** Focus on the subject, disequilibrium syndrome. Think about the pathophysiology and that brain cells are responsive to changes in osmolarity. This will assist you to choose the correct option describing neurological symptoms.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Renal and Urinary

**Health Problem:** Adult Health: Renal and Urinary: Chronic kidney disease

**Priority Concepts:** Elimination; Intracranial Regulation

CHAPTER 55
Renal and Urinary Medications

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Elimination; Safety

I. Urinary Tract Antiseptics
   A. Description
      1. Urinary tract antiseptics inhibit the growth of bacteria in the urine (Box 55-1).
      2. Act as disinfectants within the urinary tract.
      3. Used to treat acute cystitis or urinary tract infections (UTIs).
      4. Urinary tract antiseptics do not achieve effective antibacterial concentrations in blood or tissues and therefore cannot be used for infections outside the urinary tract.

B. Side and adverse effects and nursing considerations
   1. Fosfomycin
      a. The medication is available as granules that must be dissolved; instruct the client to mix the contents of a package in about ½ cup (120 mL) of cold water, stir well, and drink all of the liquid.
      b. Medications that increase gastrointestinal motility reduce the absorption of fosfomycin.
   2. Methenamine
      a. Used to treat chronic UTIs but not recommended for acute infections.
      b. Administer after meals and at bedtime to minimize gastric distress.
      c. Chronic high-dose therapy can cause bladder irritation.
      d. Methenamine can cause crystalluria and should not be used in clients with renal impairment.
      e. Decomposition of the medication
generates ammonia; therefore, it should not be used for clients with liver dysfunction.

f. Methenamine requires acidic urine with a pH of 5.5 or lower.

g. Increasing fluid intake reduces antibacterial effects by diluting the medication and raising urine pH.

h. Methenamine should not be combined with sulfonamides because of the risk of crystalluria and urinary tract injury.

i. Clients taking this medication should avoid alkalinizing agents, including over-the-counter antacids containing sodium bicarbonate or sodium carbonate.

3. Nitrofurantoin
   a. Gastrointestinal effects include anorexia, nausea, vomiting, and diarrhea; administration with milk or meals minimizes gastrointestinal distress.

   b. Pulmonary reactions include dyspnea, chest pain, chills, fever, cough, and alveolar infiltrates; these resolve in 2 to 4 days following cessation of treatment.

c. Hematological effects include agranulocytosis, leukopenia, thrombocytopenia, and megaloblastic anemia.

d. Peripheral neuropathy effects include muscle weakness, tingling sensations, and numbness.

e. Neurological effects include headache, vertigo, drowsiness, and nystagmus.

f. Allergic reactions include anaphylaxis, hives, rash, and tingling sensations around the mouth.
g. Nitrofurantoin may impart a
harmless brown color to the urine.
h. Nitrofurantoin is
contraindicated in clients with renal
impairment.
i. Instruct the client in expected side and
adverse effects, signs warranting
notification of the primary health care
provider (PHCP), and not to take
nitrofurantoin with antacids.

II. Fluoroquinolones (Box 55-2)
A. Description: Suppress bacterial growth by inhibiting an enzyme
necessary for DNA synthesis; active against a broad spectrum of
microbes
B. Side and adverse effects and nursing considerations

1. Can cause dizziness, drowsiness, gastric
distress, diarrhea, vaginitis, nausea, and vomiting
2. Adverse effects include psychoses, hallucinations,
confusion, tremors, hypersensitivity, and interstitial
nephritis.

![Warning]

With fluoroquinolones, there is an increased risk for tendonitis
and tendon rupture. The Achilles tendon is most often involved, but the
shoulder and hand tendons can also be affected. Clients at increased
risk are those over the age of 60 years, those taking corticosteroids, and
clients who have undergone organ transplant.

3. Fluoroquinolones should be used with caution
in clients with hepatic, renal, or central nervous
system (CNS) disorders.
4. Monitor client for side and adverse effects.
5. Ciprofloxacin and ofloxacin may be taken with or
without food.
6. Intravenously administered ciprofloxacin and
ofloxacin are infused slowly over 60 minutes to
minimize discomfort and vein irritation.
7. Advise the client to report dizziness,
lightheadedness, visual disturbances, increased light
sensitivity, and feelings of depression, because these
signs could indicate CNS toxicity.
8. Inform the client of signs of hepatic and renal toxicity and the importance of reporting these signs to the PHCP.

Administer oral fluoroquinolones with a full glass of water and ensure that the client maintains a urine output of at least 1200 to 1500 mL daily to minimize the development of crystalluria.

III. Sulfonamides (Box 55-3)
   A. Description: Suppress bacterial growth by inhibiting the synthesis of folic acid; active against a broad spectrum of microbes; used primarily to treat acute UTIs
   B. Side and adverse effects and nursing considerations
      1. Hypersensitivity reactions include rash, fever, and photosensitivity.
      2. Stevens-Johnson syndrome, the most severe hypersensitivity response, produces symptoms that include widespread lesions of the skin and mucous membranes, fever, malaise, and toxemia.
      3. Sulfonamides can cause hemolytic anemia, agranulocytosis, leukopenia, and thrombocytopenia; instruct the client to notify the PHCP if sore throat or fever occurs.
      4. Administer sulfonamides with caution in clients with renal impairment.
      5. Sulfonamides are contraindicated if hypersensitivity exists to sulfonamides, sulfonylureas, or thiazide or loop diuretics.
      6. Sulfonamides are contraindicated in infants younger than 2 months and in pregnant women or mothers who are breast-feeding.
      7. Sulfonamides can potentiate the effects of warfarin sodium, phenytoin, and orally administered hypoglycemics (when combined with sulfonamides, hypoglycemics may require a reduction in dosage).
      8. Instruct the client to take the medication on an empty stomach with a full glass of water.
      9. Instruct the client to complete the entire course of the prescribed medication.
     10. Instruct the client to avoid prolonged exposure to sunlight, wear protective clothing, and apply a sunscreen to exposed skin.
     11. Adults should maintain a daily urine output of at least 1200 mL by consuming 8 to 10 glasses of water each day to minimize the risk of renal damage from the medication.
12. Inform the client that some combination medications of sulfonamides can cause the urine to turn dark brown or red.

13. The sulfonamide combination of trimethoprim- sulfamethoxazole is more effective than either medication alone, because it inhibits the sequential steps in bacterial folic acid synthesis.

14. Trimethoprim-sulfamethoxazole is used cautiously with clients experiencing impaired kidney function, folate deficiency, severe allergy, or bronchial asthma.

15. An intravenous (IV) dose of trimethoprim- sulfamethoxazole is administered over 60 to 90 minutes and is not mixed with other medications.

Sulfonamides should be withheld if a rash is noted. Inform the client to contact the PHCP if a rash appears.

IV. Urinary Tract Analgesics (Box 55-4)

A. Description: A urinary tract analgesic is administered with an antibiotic because the analgesic only treats pain, not the infection.

B. Side and adverse effects
   1. Nausea
   2. Headache
   3. Vertigo

C. Nursing considerations
   1. Instruct the client that the urine will turn red or orange and could stain clothing; tears and contact lenses will also become red or orange tinged.
   2. A urinary tract analgesic is contraindicated in clients with renal or hepatic disease.
   3. The medication interferes with accurate urine testing for glucose and ketones.

V. Anticholinergics/Antispasmodics (Box 55-5)

A. Description: Used for overactive bladder (urge incontinence)

B. Side and adverse effects
   1. Anorexia, nausea, vomiting, and dry mouth
   2. Blurred vision
   3. Confusion in older clients
   4. Constipation
   5. Decreased sweating
   6. Dizziness
   7. Drowsiness
8. Dry eyes
9. Gastric distress
10. Headache
11. Tachycardia
12. Urinary retention

C. Nursing considerations
1. Extended-release capsules should not be split, chewed, or crushed.
2. Tolterodine should be used cautiously in clients with narrow-angle glaucoma.
3. Do not administer oxybutynin to clients with known hypersensitivity, gastrointestinal or genitourinary obstruction, glaucoma, severe colitis, or myasthenia gravis.
4. Do not administer propantheline to clients with narrow-angle glaucoma, obstructive uropathy, gastrointestinal disease, or ulcerative colitis.
5. Instruct the client to avoid hazardous activities because of the effects of dizziness and drowsiness.
6. Monitor intake and output.
7. Provide gum or hard candy for dry mouth.
8. Monitor for signs of toxicity (CNS stimulation) such as hypotension or hypertension, confusion, tachycardia, flushed or red face, signs of respiratory depression, nervousness, restlessness, hallucinations, and irritability.

Antispasmodic medications used to treat overactive bladder (urge incontinence) should not be used by clients diagnosed with open-angle glaucoma. These medications will block the flow of intraocular fluid and raise the intraocular pressure. This may cause permanent damage to the optic nerve.

VI. Cholinergics
A. Description: Bethanechol chloride is a cholinergic used to increase bladder tone and function and to treat nonobstructive urinary retention and neurogenic bladder.
B. Side and adverse effects
1. Headache
2. Hypotension
3. Flushing and sweating
4. Increased salivation
5. Nausea and vomiting
6. Abdominal cramps
7. Diarrhea
8. Urinary urgency
9. Bronchoconstriction
10. Transient complete heart block

C. Nursing considerations

1. Administer on an empty stomach, 1 hour before or 2 hours after meals to lessen nausea and vomiting.
2. Never administer by the intramuscular or IV route.
3. Monitor intake and output.
4. Monitor for increased bladder tone and function.
5. Monitor for cholinergic overdose (excessive salivation, sweating, involuntary urination and defecation, bradycardia, and severe hypotension).
6. Have atropine sulfate (antidote for cholinergic overdose) readily available for IV or subcutaneous administration.

VII. Medications for Preventing Organ Rejection (Box 55-6)

A. Medications include immunosuppressants, corticosteroids, cytotoxic medications, and antibodies.

B. Some medications may be used in combination to produce different actions on the immune system; combination therapy also allows for administration of the medications in lower doses, reducing the possibility of adverse effects.

C. Cyclosporine

1. Cyclosporine inhibits calcineurin and acts on T lymphocytes to suppress the production of interleukin-2, interferon-γ, and other cytokines.
2. Cyclosporine may be used to prevent rejection of allogeneic kidney, liver, and heart transplants.
3. Prednisone may be administered concurrently.
4. Oral administration of cyclosporine is preferred; IV administration is reserved for clients who cannot take the medication orally.
5. Blood levels of the medication should be measured regularly because of its nephrotoxic effects.

6. The most common adverse effects are nephrotoxicity, infection, hypertension, tremor, and hirsutism.
7. Assure the client that hirsutism is reversible; instruct on depilatory (hair removal) methods.
8. Other adverse effects include neurotoxicity, gastrointestinal effects, hyperkalemia, and hyperglycemia.
9. The risk of infection and lymphomas is increased with the use of cyclosporine.
10. Cyclosporine is contraindicated in the presence of hypersensitivity, pregnancy and breast-feeding, recent inoculation with live virus vaccines, and recent contact with an active infection such as chickenpox or herpes zoster.
11. Cyclosporine is embryotoxic, and women of childbearing age should use a mechanical form of contraception and avoid oral contraceptives.
12. The client should be informed about the possibility of renal damage and liver damage and the need for periodic liver function tests and determination of coagulation factors and blood urea nitrogen, serum creatinine, serum potassium, and blood glucose levels.
13. The client should be instructed to monitor for early signs of infection and to report these signs immediately.
14. Available in a pill form; if the client is unable to swallow the pill, instruct the client to follow the medication administration instructions exactly; dispense the oral liquid medication into a glass container using a specially calibrated pipette, mix well, and drink immediately; rinse the glass container with diluent and drink it to ensure ingestion of the complete dose; dry the outside of the pipette and return to its cover for storage.
15. To promote palatability, instruct the client to mix the liquid medication with milk, chocolate milk, or orange juice just before administration.
16. Consuming grapefruit juice is prohibited because it raises cyclosporine levels and increases the risk of toxicity.
17. Ketoconazole, erythromycin, and amphotericin B can elevate cyclosporine levels.
18. Phenytoin, phenobarbital, rifampin, and trimethoprim-sulfamethoxazole can decrease cyclosporine levels.
19. Renal damage can be intensified by the concurrent use
of other nephrotoxic medications.

D. Sirolimus
1. Sirolimus is used for the prevention of renal transplant rejection by inhibiting the response of helper T lymphocytes and B lymphocytes to cytokinesis.
2. It may be used with cyclosporine or tacrolimus and corticosteroids.
3. Increases the risk of infection, increases the risk of renal injury, increases the risk of lymphocele (a complication of renal transplant surgery), and raises cholesterol and triglyceride levels
4. Side and adverse effects include rash, acne, anemia, thrombocytopenia, joint pain, diarrhea, and hypokalemia.

E. Tacrolimus
1. Tacrolimus inhibits calcineurin and thereby prevents T cells from producing interleukin-2, interferon-γ, and other cytokines.
2. Tacrolimus is more effective than cyclosporine but is more toxic.
3. Adverse effects are similar to those of cyclosporine and include nephrotoxicity, infection, hypertension, tremor, hirsutism, neurotoxicity, gastrointestinal effects, hyperkalemia, and hyperglycemia.
4. Tacrolimus should be used cautiously in immunosuppressed clients and those with renal, hepatic, or pancreatic impairment.
5. Tacrolimus is contraindicated for clients hypersensitive to cyclosporine.
6. Monitor blood glucose levels and administer prescribed insulin or oral hypoglycemics.

F. Prednisone
1. Prednisone is a glucocorticoid that inhibits accumulation of inflammatory cells at inflammation sites.
2. Hyperglycemia and hypokalemia can occur with prednisone use; monitor glucose and serum potassium levels.
3. See Chapter 47 for additional information about prednisone.

G. Azathioprine
1. Azathioprine suppresses cell-mediated and humoral immune responses by inhibiting the proliferation of B
and T lymphocytes.

2. Can cause neutropenia and thrombocytopenia from bone marrow suppression.
3. Contraindicated in pregnancy; associated with an increased incidence of neoplasms.
4. Monitor hematocrit, white blood cell count, platelet count, liver enzyme levels, and coagulation factors.

H. Mycophenolate mofetil
1. Mycophenolate mofetil causes selective inhibition of B- and T-lymphocyte proliferation.
2. May be used with cyclosporine or tacrolimus and glucocorticoids for prophylaxis against organ rejection.
3. Adverse effects include diarrhea, severe neutropenia, vomiting, and sepsis.
4. Mycophenolate mofetil is associated with an increased risk of infection and malignancies.
5. Absorption is decreased by the use of magnesium and aluminum antacids and by cholestyramine.
6. It is contraindicated in pregnancy and during breastfeeding.
7. Instruct the client to take the medication on an empty stomach and not to open or crush capsules.
8. Instruct the client to contact the PHCP for unusual bleeding or bruising, sore throat, mouth sores, abdominal pain, or fever.

Persons who have undergone organ transplant, such as a kidney, must take the prescribed immunosuppressant medications at the same time each day to ensure that the immune system is sufficiently suppressed to prevent organ rejection.

I. Basiliximab
1. Basiliximab binds to interleukin-2 receptors on lymphocytes, resulting in diminished cell-mediated immune reactions.
2. Used primarily as an induction agent at the time of transplantation; may be used with other immunosuppressants to prevent acute rejection of transplanted kidneys.
3. Administered by the IV route; initial dose is administered within 2 hours before transplantation.
4. Side and adverse effects include headache, insomnia, dizziness, and tremors; chest pain, gastrointestinal distress, edema, shortness of breath, pain in the joints,
and slow wound healing can also occur.

J. Antithymocyte globulin, equine  
1. Antithymocyte globulin, equine, causes a decrease in the number and activity of thymus-derived lymphocytes and is used to suppress organ rejection following renal, liver, bone marrow, and heart transplantation.  
2. It is used primarily to treat acute rejection episodes.  
   3. Before the first infusion, the client should undergo intradermal skin testing to determine hypersensitivity.  
4. Because this product is made using equine and human blood components, it may carry a risk of transmitting infectious agents, such as viruses.  
5. Monitor the platelet count and report low counts to the PHCP per agency policy.  
6. Arrange for outpatient referral for repeated infusions after discharge.

VIII. Hematopoietic Growth Factors (Box 55-7)  
A. Erythropoietic growth factors  
1. Stimulate the production of red blood cells  
2. Used to treat anemia of chronic kidney disease, chemotherapy-induced anemia, anemia caused by zidovudine, and anemia in clients requiring surgery.  
3. Initial effects can be seen within 1 to 2 weeks, and the hematocrit reaches normal levels in 2 to 3 months.  
   4. Major adverse effect is hypertension.  
5. Adverse effects can also include heart failure, thrombotic effects such as stroke or myocardial infarction, and cardiac arrest.

B. Leukopoietic growth factors  
1. Stimulate the production of white blood cells (leukocytes)  
2. Used for clients undergoing myelosuppressive chemotherapy or bone marrow transplantation and those with severe chronic neutropenia.  
3. Can cause bone pain, leukocytosis, and elevation of plasma uric acid, lactate dehydrogenase, and alkaline phosphatase levels; long-term therapy has caused splenomegaly.

C. Thrombopoietic growth factor  
1. Stimulates the production of platelets  
2. Used for clients undergoing myelosuppressive chemotherapy to minimize thrombocytopenia and to decrease the need for platelet transfusions
3. Adverse effects include fluid retention, cardiac dysrhythmias, conjunctival infection, visual blurring, and papilledema.

IX. Medications for Benign Prostatic Hyperplasia (Box 55-8)
   A. Alpha blockers
      1. Relax bladder neck muscles and muscle fibers in the prostate, allowing urine to pass more easily
      2. Adverse effects include dizziness and retrograde ejaculation
   B. 5a-alpha reductase inhibitors
      1. Shrinks the prostate by preventing hormonal changes that result in growth of the prostate
      2. May take up to 6 months to be effective
      3. Adverse effects include retrograde ejaculation

---

**Box 55-1**

**Urinary Tract Antiseptics**

- Amoxicillin
- Cefixime
- Fosfomycin
- Methenamine
- Nitrofurantoin

**Alpha blockers**

- Alfuzosin
- Doxazosin
- Tamsulosin
- Silodosin

**5α-alpha reductase inhibitors**

- Finasteride
- Dutasteride
Practice Questions

661. A client who has a cold is seen in the emergency department with an inability to void. Because the client has a history of benign prostatic hyperplasia, the nurse determines that the client should be questioned about the use of which medication?
   1. Diuretics
   2. Antibiotics
   3. Antilipemics
   4. Decongestants

662. Nitrofurantoin is prescribed for a client with a urinary tract infection. The client contacts the nurse and reports a cough, chills, fever, and difficulty breathing. The nurse should make which interpretation about the client’s complaints?
   1. The client may have contracted the flu.
   2. The client is experiencing anaphylaxis.
   3. The client is experiencing expected effects of the medication.
   4. The client is experiencing a pulmonary reaction requiring cessation of the medication.

663. The nurse is providing discharge instructions to a client receiving trimethoprim-sulfamethoxazole. Which instruction should be included in the list?
   1. Advise that sunscreen is not needed.
   2. Drink 8 to 10 glasses of water per day.
   3. Decrease the dosage when symptoms are improving to prevent an allergic response.
   4. If the urine turns dark brown, call the primary health care provider (PHCP) immediately.

664. Trimethoprim-sulfamethoxazole is prescribed for a client. The nurse should instruct the client to report which symptom if it develops during the course of this medication therapy?
   1. Nausea
   2. Diarrhea
   3. Headache
   4. Sore throat

665. Phenazopyridine is prescribed for a client with a urinary tract infection. The nurse evaluates that the medication is effective based on which observation?
   1. Urine is clear amber.
   2. Urination is not painful.
   3. Urge incontinence is not present.
   4. A reddish-orange discoloration of the urine is present.

666. Bethanechol chloride is prescribed for a client with urinary retention. Which disorder would be a contraindication to the administration of this medication?
   1. Gastric atony
   2. Urinary strictures
   3. Neurogenic atony
4. Gastroesophageal reflux

667. The nurse, who is administering bethanechol chloride, is monitoring for cholinergic overdose associated with the medication. The nurse should check the client for which sign of overdose?
   1. Dry skin
   2. Dry mouth
   3. Bradycardia
   4. Signs of dehydration

668. Oxybutynin chloride is prescribed for a client with urge incontinence. Which sign would indicate a possible toxic effect related to this medication?
   1. Pallor
   2. Drowsiness
   3. Bradycardia
   4. Restlessness

669. Following kidney transplantation, cyclosporine is prescribed for a client. Which laboratory result would indicate an adverse effect from the use of this medication?
   1. Hemoglobin level of 14.0 g/dL (140 mmol/L)
   2. Creatinine level of 0.6 mg/dL (53 mcmol/L)
   3. Blood urea nitrogen level of 25 mg/dL (8.8 mmol/L)
   4. Fasting blood glucose level of 99 mg/dL (5.5 mmol/L)

670. The nurse is providing dietary instructions to a client who has been prescribed cyclosporine. Which food item should the nurse instruct the client to exclude from the diet?
   1. Red meats
   2. Orange juice
   3. Grapefruit juice
   4. Green, leafy vegetables

671. Tacrolimus is prescribed for a client who underwent a kidney transplant. Which instruction should the nurse include when teaching the client about this medication?
   1. Eat at frequent intervals to avoid hypoglycemia.
   2. Take the medication with a full glass of grapefruit juice.
   3. Change positions carefully due to risk of orthostatic hypotension.
   4. Take the oral medication every 12 hours at the same times every day.

672. The nurse is reviewing the laboratory results for a client receiving tacrolimus. Which laboratory result would indicate to the nurse that the client is experiencing an adverse effect of the medication?
   1. Potassium level of 3.8 mEq/L (3.8 mmol/L)
   2. Platelet count of 300,000 mm$^3$ (300 $\times 10^9$/L)
   3. Fasting blood glucose of 200 mg/dL (11.1 mmol/L)
   4. White blood cell count of 6000 mm$^3$ (6.0 $\times 10^9$/L)

673. The nurse receives a call from a client concerned about eliminating brown-colored urine after taking nitrofurantoin for a urinary tract infection. The nurse should make which appropriate response?
   1. “Continue taking the medication; the brown urine occurs and is not harmful.”
2. “Take magnesium hydroxide with your medication to lighten the urine color.”
3. “Discontinue taking the medication and make an appointment for a urine culture.”
4. “Decrease your medication to half the dose, because your urine is too concentrated.”

674. A client with chronic kidney disease is receiving epoetin alfa. Which laboratory result would indicate a therapeutic effect of the medication?
   1. Hematocrit of 33% (0.33)
   2. Platelet count of 400,000 mm$^3$ (400 × 10$^9$/L)
   3. White blood cell count of 6000 mm$^3$ (6.0 × 10$^9$/L)
   4. Blood urea nitrogen level of 15 mg/dL (5.4 mmol/L)

675. A client with a urinary tract infection is receiving ciprofloxacin by the intravenous (IV) route. The nurse appropriately administers the medication by performing which action?
   1. Infusing slowly over 60 minutes
   2. Infusing in a light-protective bag
   3. Infusing only through a central line
   4. Infusing rapidly as a direct IV push medication

**Answers**

661. Answer: 4

**Rationale:** In the client with benign prostatic hyperplasia, episodes of urinary retention can be triggered by certain medications, such as decongestants, anticholinergics, and antidepressants. These medications lessen the voluntary ability to contract the bladder. The client should be questioned about the use of these medications if he has urinary retention. Diuretics increase urine output. Antibiotics and antilipemics do not affect ability to urinate.

**Test-Taking Strategy:** Focus on the subject, medications that could exacerbate or contribute to urinary retention in the client with benign prostatic hyperplasia. Recalling that medications that contain anticholinergics may cause urinary retention will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing
**Client Needs:** Physiological Integrity
**Integrated Process:** Nursing Process—Assessment
**Content Area:** Adult Health: Renal and Urinary
**Health Problem:** Adult Health: Renal and Urinary: Obstructive problems
**Priority Concepts:** Elimination; Safety
**Reference:** Lewis et al. (2017), p. 1273.

662. Answer: 4

**Rationale:** Nitrofurantoin can induce 2 kinds of pulmonary reactions: acute and subacute. Acute reactions, which are most common, manifest with dyspnea, chest
pain, chills, fever, cough, and alveolar infiltrates. These symptoms resolve 2 to 4
days after discontinuing the medication. Acute pulmonary responses are thought to
be hypersensitivity reactions. Subacute reactions are rare and occur during
prolonged treatment. Symptoms (e.g., dyspnea, cough, malaise) usually regress over
weeks to months following nitrofurantoin withdrawal. However, in some clients,
permanent lung damage may occur. The remaining options are incorrect
interpretations.

Test-Taking Strategy: Focus on the subject, interpreting the client’s complaints,
and the information in the question. Note the relationship of the information in the
question and the words pulmonary reaction in the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Analysis
Content Area: Pharmacology: Renal and Urinary Medications: Urinary tract
antiseptics
Health Problem: Adult Health: Renal and Urinary: Inflammation/Infections
Priority Concepts: Clinical Judgment; Infection

663. Answer: 2

Rationale: Each dose of trimethoprim-sulfamethoxazole should be administered
with a full glass of water, and the client should maintain a high fluid intake to avoid
crystalluria. The medication is more soluble in alkaline urine. The client should not
be instructed to taper or discontinue the dose. Clients should be advised to use
sunscreen since the skin becomes sensitive to the sun. Some forms of trimethoprim-
sulfamethoxazole cause urine to turn dark brown or red. This does not indicate the
need to notify the PHCP.

Test-Taking Strategy: Focus on the subject, client instructions for trimethoprim-
sulfamethoxazole. Recalling that this medication is used to treat urinary tract
infections will direct you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Pharmacology: Renal and Urinary Medications: Sulfonamides
Health Problem: Adult Health: Renal and Urinary: Inflammation/Infections
Priority Concepts: Client Teaching; Infection

664. Answer: 4

Rationale: Clients taking trimethoprim-sulfamethoxazole should be informed
about early signs and symptoms of blood disorders that can occur from this
medication. These include sore throat, fever, and pallor, and the client should be
instructed to notify the primary health care provider (PHCP) if these occur. The
other options do not require PHCP notification.

Test-Taking Strategy: Focus on the subject, the symptoms to report. Knowledge
that this medication can cause blood dyscrasias will direct you to the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Pharmacology: Renal and Urinary Medications: Sulfonamides  
**Health Problem:** Adult Health: Renal and Urinary: Inflammation/Infections  
**Priority Concepts:** Client Education; Infection  

665. **Answer:** 2

**Rationale:** Phenazopyridine is a urinary analgesic. It is effective when it eliminates pain and burning with urination. It does not eliminate the bacteria causing the infection, so it would not make the urine clear amber. It does not treat urge incontinence. It will cause the client to have reddish-orange discoloration of urine, but this is a side effect of the medication, not the desired effect.

**Test-Taking Strategy:** Note the strategic word, *effective*. Focus on the subject, effectiveness of phenazopyridine. Recalling the classification of this medication and that it is a urinary analgesic will direct you to the correct option.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Pharmacology: Renal and Urinary Medications: Urinary tract analgesics  
**Health Problem:** Adult Health: Renal and Urinary: Inflammation/Infections  
**Priority Concepts:** Elimination; Pain  

666. **Answer:** 2

**Rationale:** Bethanechol chloride can be hazardous to clients with urinary tract obstruction or weakness of the bladder wall. The medication has the ability to contract the bladder and thereby increase pressure within the urinary tract. Elevation of pressure within the urinary tract could damage or rupture the bladder in clients with these conditions.

**Test-Taking Strategy:** Focus on the subject, a contraindication for the use of the medication. Noting that the medication is used for urinary retention may assist in directing you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Analysis  
**Content Area:** Pharmacology: Renal and Urinary Medications: Cholinergics  
**Health Problem:** Adult Health: Renal and Urinary: Obstructive problems  
**Priority Concepts:** Elimination; Safety  
**Reference:** Skidmore-Roth (2017), pp. 141-142.

667. **Answer:** 3
**Rationale:** Cholinergic overdose of bethanechol chloride produces manifestations of excessive muscarinic stimulation such as salivation, sweating, involuntary urination and defecation, bradycardia, and severe hypotension. Remember that the sympathetic nervous system speeds the heart rate and the cholinergic (parasympathetic) nervous system slows the heart rate. Treatment includes supportive measures and the administration of atropine sulfate (anticholinergic) subcutaneously or intravenously.

**Test-Taking Strategy:** Focus on the subject, signs of cholinergic overdose. Noting that options 1, 2, and 4 are comparable or alike will assist in eliminating these options.

**Level of Cognitive Ability:** Analyzing
**Client Needs:** Physiological Integrity
**Integrated Process:** Nursing Process—Assessment
**Content Area:** Pharmacology: Renal and Urinary Medications: Cholinergics
**Health Problem:** N/A
**Priority Concepts:** Elimination; Safety
**Reference:** Lilley et al. (2017), pp. 327-328.

668. **Answer:** 4

**Rationale:** Toxicity (overdosage) of oxybutynin produces central nervous system excitation, such as nervousness, restlessness, hallucinations, and irritability. Other signs of toxicity include hypotension or hypertension, confusion, tachycardia, flushed or red face, and signs of respiratory depression. Drowsiness is a frequent side effect of the medication but does not indicate overdosage.

**Test-Taking Strategy:** Focus on the subject, signs of toxicity (overdosage) of oxybutynin. Remember that restlessness is a sign of toxicity.

**Level of Cognitive Ability:** Analyzing
**Client Needs:** Physiological Integrity
**Integrated Process:** Nursing Process—Assessment
**Content Area:** Pharmacology: Renal and Urinary Medications: Anticholinergics/antispasmodics
**Priority Concepts:** Clinical Judgment; Safety
**Health Problem:** N/A

669. **Answer:** 3

**Rationale:** Cyclosporine is an immunosuppressant. Nephrotoxicity can occur from the use of cyclosporine. Nephrotoxicity is evaluated by monitoring for elevated blood urea nitrogen and serum creatinine levels. The normal blood urea nitrogen level is 10 to 20 mg/dL (3.6 to 7.1 mmol/L). The normal creatinine level for a male is 0.6 to 1.2 mg/dL (53 to 106 mcmol/L) and for a female is 0.5 to 1.1 mg/dL (44 to 97 mcmol/L). Cyclosporine can lower complete blood cell count levels. A normal hemoglobin is 14 to 18 g/dL (140 to 180 mmol/L) for a male and 12 to 16 g/dL (120 to 160 mmol/L) for a female. A normal hemoglobin is not an adverse effect. Cyclosporine does affect the glucose level. The normal fasting glucose is 70 to 99.
Test-Taking Strategy: Focus on the subject, the adverse effects of cyclosporine. Recall that cyclosporine can be nephrotoxic. The correct option is the only one that indicates an increased level of a renal function test. Also, recalling the normal laboratory reference levels will direct you to the correct option, the only abnormal level.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Analysis
Content Area: Pharmacology: Renal and Urinary Medications: Organ rejection prevention
Health Problem: Adult Health: Immune: Transplantation
Priority Concepts: Immunity; Safety
Reference: Lewis et al. (2017), pp. 211, 1026.

670. Answer: 3

Rationale: A compound present in grapefruit juice inhibits metabolism of cyclosporine through the cytochrome P450 system. As a result, consumption of grapefruit juice can raise cyclosporine levels by 50% to 100%, thereby greatly increasing the risk of toxicity. Red meats, orange juice, and green, leafy vegetables do not interact with the cytochrome P450 system.

Test-Taking Strategy: Focus on the subject, the item to exclude from the diet. Recall that grapefruit juice is contraindicated with many medications. Use of general pharmacology guidelines will direct you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Pharmacology: Renal and Urinary Medications: Organ rejection prevention
Health Problem: N/A
Priority Concepts: Client Education; Safety

671. Answer: 4

Rationale: Tacrolimus is a potent immunosuppressant used to prevent organ rejection in transplant clients. It is important that the medication be taken at 12-hour intervals to maintain a stable blood level to prevent organ rejection. Adverse effects include hyperglycemia and hypertension, so the client does not eat frequently to avoid hypoglycemia or use precautions to avoid orthostatic hypotension. Tacrolimus is metabolized through the cytochrome P450 system, so grapefruit juice is not allowed.

Test-Taking Strategy: Focus on the subject, teaching a transplant client regarding tacrolimus. Focus on the goal of avoiding organ rejection by maintaining a stable level of tacrolimus in the blood by taking the medication at regular intervals every day.
Rationale: A fasting blood glucose level of 200 mg/dL (11.1 mmol/L) is significantly elevated above the normal range of 70 to 99 mg/dL (3.9–5.5 mmol/L) and suggests an adverse effect. Recall that fasting blood glucose levels are sometimes based on primary health care provider preference. Other adverse effects include neurotoxicity evidenced by headache, tremor, and insomnia; gastrointestinal effects such as diarrhea, nausea, and vomiting; hypertension; and hyperkalemia. The remaining options identify normal reference levels. The normal potassium level is 3.5 to 5.0 mEq/L (3.5 to 5.0 mmol/L). The normal platelet count is 150,000 to 400,000 mm$^3$ (150 to 400 × 10$^9$/L). The normal white blood cell count is 5000 to 10,000 mm$^3$ (5 to 10 × 10$^9$/L).

Test-Taking Strategy: Focus on the subject, an adverse effect. Note that options 1, 2, and 4 are comparable or alike and represent normal values. The correct option has the only abnormal value, reflecting an elevation.

Rationale: Nitrofurantoin imparts a harmless brown color to the urine, and the medication should not be discontinued until the prescribed dose is completed. Magnesium hydroxide will not affect urine color. In addition, antacids should be avoided because they interfere with medication effectiveness.

Test-Taking Strategy: Focus on the subject, brown-colored urine. Option 2 can be eliminated, because antacids should be avoided as a result of their interference with the effectiveness of nitrofurantoin. In addition, magnesium hydroxide will not have an effect on urine color. Next, eliminate options 3 and 4, because the nurse should not tell the client to discontinue medication or alter the dose.
Rationale: Epoetin alfa is synthetic erythropoietin, which the kidneys produce to stimulate red blood cell production in the bone marrow. It is used to treat anemia associated with chronic kidney disease. The normal hematocrit level is 42% to 52% (0.42 to 0.52) for males and 37% to 47% (0.37 to 0.47) for females. Therapeutic effect is seen when the hematocrit reaches between 30% and 33% (0.30 and 0.33). The normal platelet count is 150,000 to 400,000 mm$^3$ (150 to 400 × 10$^9$/L). The normal blood urea nitrogen level is 10 to 20 mg/dL (3.6 to 7.1 mmol/L). The normal white blood cell count is 5000 to 10,000 mm$^3$ (5 to 10 × 10$^9$/L). Platelet production, white blood cell production, and blood urea nitrogen do not respond to erythropoietin.

Test-Taking Strategy: Focus on the subject, a therapeutic effect. Relate the name of the medication, epoetin alfa, to the potential action or effect of erythropoietin. The only laboratory test that would reflect the effect of this medication is a hematocrit of 33% (0.33), found in the correct option.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Pharmacology: Hematological Medications: Hematopoietic agents
Health Problem: Adult Health: Renal and Urinary: Chronic kidney disease
Priority Concepts: Clinical Judgment; Evidence

Rationale: Ciprofloxacin is prescribed for treatment of mild, moderate, severe, and complicated infections of the urinary tract, lower respiratory tract, and skin and skin structure. A single dose is administered slowly over 60 minutes to minimize discomfort and vein irritation. Ciprofloxacin is not light-sensitive, may be infused through a peripheral IV access, and is not given by IV push method.

Test-Taking Strategy: Focus on the subject, the appropriate way to administer an IV medication ciprofloxacin. Recall that this medication has adverse effects, so IV push would not be the recommended method of administration. Eliminate option 3 because of the closed-ended word, “only.” Next, it is necessary that the presence of light does not affect the integrity of this medication.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Pharmacology: Renal and Urinary Medications: Urinary tract antiseptics
Health Problem: Adult Health: Renal and Urinary: Inflammation/Infections
Priority Concepts: Clinical Judgment; Safety
Introduction

Pyramid to Success

Pyramid Points focus on safety and nursing interventions for clients with impairment of sight or hearing and on the nursing care related to disorders such as cataracts, glaucoma, and retinal detachment. Communicating with clients who are visually or hearing impaired is also a priority. Emergency interventions for eye and ear disorders and injuries are a priority point. Pyramid Points also focus on client instructions related to medication administration, sensory perceptual alterations and safety issues, and available support systems.

Client Needs: Learning Objectives

Safe and Effective Care Environment

Caring for the recipient of a tissue (corneal) donation
Communicating with the interprofessional health care team
Establishing priorities
Maintaining asepsis with procedures and treatments
Maintaining standard and other precautions
Preventing accidents that can occur as a result of sensory impairments
Upholding client rights
Verifying that informed consent for invasive procedures is obtained

Health Promotion and Maintenance

Discussing changes that occur with the aging process
Discussing expected body image changes and self-care deficits
Implementing measures for the prevention and early detection of health problems and diseases related to the eye and the ear
Performing physical assessments of the eye and ear
Providing home care instructions following procedures related to the eye and ear
Providing instructions regarding activity limitations or postoperative activities
Providing instructions regarding the administration of eye and ear medications
Teaching regarding the importance of compliance with the prescribed therapy

Psychosocial Integrity
Assessing the client’s ability to cope with feelings of isolation, fear, or anxiety regarding a possible change in vision and/or hearing status, and loss of independence
Discussing role changes
Identifying family support systems
Informing the client about available community resources
Monitoring for sensory perceptual alterations
Using appropriate communication techniques for impaired vision and hearing

**Physiological Integrity**

Monitoring for complications related to procedures
Monitoring for expected responses to therapy
Providing care for assistive devices such as eyeglasses, contact lenses, and hearing aids
Taking action in medical emergencies
Priority Concepts

Safety, Sensory Perception

I. Anatomy and Physiology of the Eye
   A. The eye
      1. The eye is 1 inch (2.5 cm) in diameter and is located in the anterior portion of the orbit.
      2. The orbit is the bony structure of the skull that surrounds the eye and offers protection to the eye.
   B. Layers of the eye
      1. External layer
         a. The fibrous coat that supports the eye
         b. Contains the cornea, the dense transparent outer layer
         c. Contains the sclera, the fibrous “white of the eye”
      2. Middle layer
         a. Called the uveal tract
         b. Consists of the choroid, ciliary body, and iris
         c. The choroid is the dark brown membrane located between the sclera and the retina that has dark pigmentation to prevent light from reflecting internally.
         d. The choroid lines most of the sclera and is attached to the retina but can detach easily from the sclera.
         e. The choroid contains many blood vessels and supplies nutrients to the retina.
         f. The ciliary body connects the choroid with the iris and secretes aqueous humor that helps give the eye its shape; the muscles of the ciliary body control the thickness of the lens.
         g. The iris is the colored portion of the
eye, located in front of the lens, and it has a central circular opening called the *pupil*. The pupil controls the amount of light (darkness produces dilation and light produces constriction) admitted into the retina.

3. Internal layer

   a. Consists of the retina, a thin, delicate structure in which the fibers of the optic nerve are distributed.
   b. The retina is bordered externally by the choroid and sclera and internally by the vitreous.
   c. The retina is the visual receptive layer of the eye in which light waves are changed into nerve impulses; it contains blood vessels and photoreceptors called *rods* and *cones*.

C. Vitreous body

   1. Contains a gelatinous substance that occupies the vitreous chamber, the space between the lens and the retina
   2. The vitreous body transmits light and gives shape to the posterior eye.

D. Vitreous

   1. Gel-like substance that maintains the shape of the eye
   2. Provides additional physical support to the retina

E. Rods and cones

   1. Rods are responsible for peripheral vision and function at reduced levels of illumination.
   2. Cones function at bright levels of illumination and are responsible for color vision and central vision.

F. Optic disc

   1. It is a creamy pink to white depressed area in the retina.
   2. The optic nerve enters and exits the eyeball at this area.
   3. This area is called the *blind spot* because it contains only nerve fibers, lacks photoreceptor cells, and is insensitive to light.

G. Macula lutea

   1. Small, oval, yellowish-pink area located laterally and temporally to the optic disc
   2. The central depressed part of the macula is the
fovea centralis, the area of sharpest and keenest vision, where most acute vision occurs.
3. Its functions include central vision, night and color vision, and motion detection.

H. Aqueous humor
1. A clear, watery fluid that fills the anterior and posterior chambers of the eye
2. It is produced by the ciliary processes, and the fluid drains into the canal of Schlemm.
3. The anterior chamber lies between the cornea and the iris.
4. The posterior chamber lies between the iris and the lens.

I. Canal of Schlemm: Passageway that extends completely around the eye; it permits fluid to drain out of the eye into the systemic circulation so that a constant intraocular pressure (IOP) is maintained.

J. Lens
1. Transparent convex structure behind the iris and in front of the vitreous body
2. The lens bends rays of light so that the light falls on the retina.
3. The curve of the lens changes to focus on near or distant objects.

K. Conjunctivae: Thin, transparent mucous membranes of the eye that line the posterior surface of each eyelid, located over the sclera

L. Lacrimal gland: Produces tears that are drained through the punctum into the lacrimal duct and sac

M. Eye muscles
1. Muscles do not work independently; each muscle works with the muscle that produces the opposite movement.
2. Rectus muscles exert their pull when the eye turns temporally.
3. Oblique muscles exert their pull when the eye turns nasally.

N. Nerves
1. Cranial nerve II: Optic nerve (sight)
2. Cranial nerve III: Oculomotor (eye movement)
3. Cranial nerve IV: Trochlear (eye movement)
4. Cranial nerve VI: Abducens (eye movement)

O. Blood vessels
1. The ophthalmic artery is the major artery supplying the structures in the eye.
2. The ophthalmic veins drain the blood from the eye.

II. Assessment of Vision (see Chapter 12)

III. Diagnostic Tests for the Eye

A. Fluorescein angiography

1. Description

a. A detailed imaging and recording of ocular circulation by a series of photographs taken after the administration of a dye

b. Used to assess problems with retinal circulation, such as those that occur in diabetic retinopathy, retinal bleeding, and macular degeneration, or to rule out intraocular tumors

2. Preprocedure interventions

a. Assess the client for allergies and previous reactions to dyes.

b. An informed consent is necessary.

c. A mydriatic medication, which causes pupil dilation, is instilled into the eye 1 hour before the test.

d. The dye is injected into a vein of the client’s arm.

e. Inform the client that the dye may cause the skin to appear yellow for several hours after the test and is eliminated gradually through the urine. Urine may be bright green or orange for up to 2 days following the procedure.

f. The client may experience nausea, vomiting, sneezing, paresthesia of the tongue, or pain at the injection site.

g. If hives appear, antihistamines such as diphenhydramine are administered as prescribed.

3. Postprocedure interventions

a. Encourage rest.

b. Encourage fluid intake to assist in eliminating the dye.

c. Remind the client that the yellow skin appearance will disappear.

d. Inform the client that the urine will appear bright green or orange until the dye is excreted.

e. Advise the client to avoid direct sunlight for a few hours after the test
and to wear sunglasses, if staying indoors is not possible.
f. Inform the client that the photophobia will continue until pupil size returns to normal.

B. Computed tomography (CT)
   1. Description
      a. The test is performed to examine the eye, bony structures around the eye, and extraocular muscles.
      b. Contrast material may be used unless eye trauma is suspected.
   2. Interventions
      a. No special client preparation or follow-up care is required.
      b. Instruct the client that he or she will be positioned in a confined space and will need to keep the head still during the procedure.
      c. Ask about and document allergies and/or previous exposure to contrast.

C. Slit lamp
   1. Description
      a. Allows examination of the anterior ocular structures under microscopic magnification.
      b. The client leans on a chin rest to stabilize the head while a narrowed beam of light is aimed so that it illuminates only a narrow segment of the eye.
   2. Interventions: Advise the client about the brightness of the light and the need to look forward at a point over the examiner’s ear.

D. Corneal staining
   1. Description
      a. A topical dye is instilled into the conjunctival sac to outline irregularities of the corneal surface that are not easily visible.
      b. The eye is viewed through a blue filter, and a bright green color indicates areas of a nonintact corneal epithelium.
   2. Interventions
      a. If the client wears contact lenses, the lenses must be removed.
      b. The client is instructed to blink after the
E. Tonometry

1. Description: The test is used primarily to assess for an increase in IOP and potential glaucoma.
2. Noncontact tonometry
   a. No direct contact with the client’s cornea is needed, and no topical eye anesthetic is needed.
   b. A puff of air is directed at the cornea to indent the cornea, which can be unpleasant and may startle the client.
   c. It is a less accurate method of measurement compared with contact tonometry.
3. Contact tonometry
   a. Requires a topical anesthetic
   b. A flattened cone is brought into contact with the cornea, and the amount of pressure needed to flatten the cornea is measured.
   c. The client must be instructed to avoid rubbing the eye following the examination if the eye has been anesthetized because of the potential for scratching the cornea.

F. Ultrasound: Procedure is similar to an ultrasound procedure done in other parts of the body and is done to detect lesions or tumors in the eye.

G. Magnetic resonance imaging (MRI): Similar to an MRI done in other parts of the body; refer to Chapter 58 for additional information on MRI.

IV. Problems of the Eye

A. Risk factors related to eye problems (Box 56-1)

B. Refractive errors
   1. Description
      a. Refraction is the bending of light rays; any problem associated with eye length or refraction can lead to
refractive errors.

b. **Myopia** (nearsightedness): Refractive ability of the eye is too strong for the eye length; images are bent and fall in front of, not on, the retina.

c. **Hyperopia** (farsightedness): Refractive ability of the eye is too weak; images are focused behind the retina.

d. **Presbyopia**: Loss of lens elasticity because of aging; less able to focus the eye for close work and images fall behind the retina.

e. **Astigmatism**: Occurs because of the irregular curvature of the cornea; image focuses at 2 different points on the retina.

2. **Assessment**

a. Refractive errors are diagnosed through a process called *refraction*.

b. The client views an eye chart while various lenses of different strengths are systematically placed in front of the eye and is asked whether the lenses sharpen or worsen the vision.

3. **Nonsurgical interventions**: Eyeglasses or contact lenses

4. **Surgical interventions**

a. Radial keratotomy: Incisions are made through the peripheral cornea to flatten the cornea, which allows the image to be focused closer to the retina; used to treat myopia.

b. Photorefractive keratotomy: A laser beam is used to remove small portions of the corneal surface to reshape the cornea to focus an image properly on the retina; used to treat myopia and astigmatism.

c. Laser-assisted in-situ keratomileusis (LASIK): The superficial layers of the cornea are lifted as a flap, a laser reshapes the deeper corneal layers, and then the corneal flap is replaced; used to treat hyperopia, myopia, and astigmatism.

d. Corneal ring: The shape of the cornea is changed by placing a flexible ring in the outer edges of the cornea; used to
C. Legal blindness

1. Description: In the client who is legally blind, the best visual acuity with corrective lenses in the better eye is 20/200 or less, or the visual field is no greater than 20 degrees in its widest diameter in the better eye.

2. Interventions
   
   a. When speaking to the client who has limited sight or is blind, the nurse should use a normal tone of voice.
   b. Alert the client when approaching.
   c. Orient the client to the environment.
   d. Use a focal point and provide further orientation to the environment from that focal point; ensure that the client has a clear pathway.
   e. Allow the client to touch objects in the room.
   f. Use the clock placement of foods on the meal tray to orient the client.
   g. Promote independence as much as is possible.
   h. Provide radios, televisions, and clocks that give the time orally, or provide a Braille watch.
   i. When ambulating, allow the client to grasp the nurse’s arm at the elbow; the nurse keeps her or his arm close to the body so that the client can detect the direction of movement.
   j. Instruct the client to remain 1 step behind the nurse when ambulating.
   k. Instruct the client in the use of the cane for the blind, which is differentiated from other canes by its straight shape and white color with red tip.
   l. Instruct the client that the cane is held in the dominant hand several inches (centimeters) off the floor.
   m. Instruct the client that the cane sweeps the ground where the client’s foot will be placed next to determine the presence of obstacles.

D. Cataracts (Fig. 56-1)

1. Description
   
   a. A cataract is an opacity of the lens that distorts the image projected onto the
retina and that can progress to blindness.

b. Causes include the aging process (senile cataracts), heredity (congenital cataracts), and injury (traumatic cataracts); cataracts also can result from another eye disease (secondary cataracts).

c. Causes of secondary cataracts include diabetes mellitus, maternal rubella, severe myopia, ultraviolet light exposure, and medications such as corticosteroids.

d. Intervention is indicated when visual acuity has been reduced to a level that the client finds unacceptable or that adversely affects her or his lifestyle.

2. Assessment

   a. Blurred vision and decreased color perception are early signs.

   b. Diplopia, reduced visual acuity, absence of the red reflex, and the presence of a white pupil are late signs. Pain or eye redness is associated with age-related cataract formation.

   c. Loss of vision is gradual.

3. Interventions

   a. Surgical removal of the lens, 1 eye at a time, is performed.

   b. With extracapsular extraction, the lens is lifted out without removing the lens capsule; the procedure may be performed by phacoemulsification, in which the lens is broken up by ultrasonic vibrations and extracted.

   c. With intracapsular extraction, the lens and capsule are removed completely.

   d. A partial iridectomy may be performed with the lens extraction to prevent acute secondary glaucoma.

   e. A lens implantation may be performed at the time of the surgical procedure.

4. Preoperative interventions

   a. Instruct the client regarding the postoperative measures such as the
importance of hand washing and measures to prevent or decrease IOP, such as bending over, coughing, straining, and rubbing the eye.
b. Stress to the client that care after surgery requires instillation of various types of eye drops several times a day for 2 to 4 weeks.
c. Administer eye medications preoperatively, including mydriatics and cycloplegics as prescribed.

5. Postoperative interventions
   a. Elevate the head of the bed 30 to 45 degrees.
   b. Turn the client to the back or nonoperative side.
   c. Maintain an eye patch as prescribed; orient the client to the environment.
   d. Position the client’s personal belongings to the nonoperative side.
   e. Use side rails for safety (per agency guidelines).
   f. Assist with ambulation.

6. Client education (Box 56-2)

E. Glaucoma

1. Description
   a. A group of ocular diseases resulting in increased IOP
   b. IOP is the fluid (aqueous humor) pressure within the eye (normal IOP is 10 to 21 mm Hg).
   c. Increased IOP results from inadequate drainage of aqueous humor from the canal of Schlemm or overproduction of aqueous humor.
   d. The condition damages the optic nerve and can result in blindness.
   e. The gradual loss of visual fields may go unnoticed, because central vision is unaffected.

2. Types
   a. Primary open-angle glaucoma (POAG) results from obstruction to outflow of aqueous humor and is the most common type.
b. Primary angle-closure glaucoma (PACG) results from blocking the outflow of aqueous humor into the trabecular meshwork; causes include lens or pupil dilation from medications or sympathetic stimulation.

3. Assessment

a. Early signs include diminished accommodation and increased IOP.

b. POAG: Painless, and vision changes are slow; results in “tunnel” vision

c. PACG: Blurred vision, halos around lights, and ocular erythema

4. Interventions for acute angle-closure glaucoma

**Acute angle-closure glaucoma is a medical emergency that causes sudden eye pain and possible nausea and vomiting.**

a. Treat acute angle-closure glaucoma as a medical emergency.

b. Administer medications as prescribed to lower IOP.

c. Prepare the client for peripheral iridectomy, which allows aqueous humor to flow from the posterior to the anterior chamber.

5. Interventions for the client with glaucoma

a. Instruct the client on the importance of medications to constrict the pupils (miotics), to decrease the production of aqueous humor (carbonic anhydrase inhibitors), and to decrease the production of aqueous humor and IOP (beta blockers).

b. Instruct the client about the need for lifelong medication use, to wear a MedicAlert bracelet, to avoid anticholinergic medications to prevent increased IOP, and to contact the primary health care provider (PHCP) before taking medications, including over-the-counter medications.

c. Instruct the client to report eye pain, halos around the eyes, and changes in vision to the PHCP.
d. Instruct the client that when maximal medical therapy has failed to halt the progression of visual field loss and optic nerve damage, surgery will be recommended.

e. Prepare the client for trabeculectomy as prescribed, which allows drainage of aqueous humor into the conjunctival spaces by the creation of an opening.

F. Retinal detachment

1. Description

a. Detachment or separation of the retina from the epithelium
b. Occurs when the layers of the retina separate because of the accumulation of fluid between them, or when both retinal layers elevate away from the choroid as a result of a tumor

c. Partial detachment becomes complete if untreated.

d. When detachment becomes complete, blindness occurs.

2. Assessment

a. Flashes of light
b. Floaters or black spots (signs of bleeding)

c. Increase in blurred vision
d. Sense of a curtain being drawn over the eye

e. Loss of a portion of the visual field; painless loss of central or peripheral vision

3. Immediate interventions

a. Provide bed rest.
b. Cover both eyes with patches as prescribed to prevent further detachment.

c. Speak to the client before approaching.
d. Position the client’s head as prescribed.

e. Protect the client from injury.
f. Avoid jerky head movements.
g. Minimize eye stress.
h. Prepare the client for a surgical procedure as prescribed.

4. Surgical procedures
a. Draining fluid from the subretinal space so that the retina can return to the normal position
b. Sealing retinal breaks by cryosurgery, a cold probe applied to the sclera, to stimulate an inflammatory response leading to adhesions
c. Diathermy, the use of an electrode needle and heat through the sclera, to stimulate an inflammatory response
d. Laser therapy, to stimulate an inflammatory response and seal small retinal tears before the detachment occurs
e. Scleral buckling, to hold the choroid and retina together with a splint until scar tissue forms, closing the tear (Fig. 56-2)
f. Insertion of gas or silicone oil to promote reattachment; these agents float against the retina to hold it in place until healing occurs.

5. Postoperative interventions
   a. Maintain eye patches as prescribed.
   b. Monitor for hemorrhage.
   c. Prevent nausea and vomiting and monitor for restlessness, which can cause hemorrhage.
   d. Monitor for sudden, sharp eye pain (notify the PHCP).
   e. Encourage deep breathing but avoid coughing.
   f. Provide bed rest as prescribed.
   g. Position the client as prescribed (positioning depends on the location of the detachment).
   h. Administer eye medications as prescribed.
   i. Assist the client with activities of daily living.
   j. Avoid sudden head movements or anything that increases IOP.
   k. Instruct the client to limit reading for 3 to 5 weeks.
   l. Instruct the client to avoid squinting, straining and constipation, lifting heavy objects, and bending from the waist.
m. Instruct the client to wear dark glasses during the day and an eye patch at night.

n. Encourage follow-up care because of the danger of recurrence or occurrence in the other eye.

G. Macular degeneration

1. A deterioration of the macula, the area of central vision
2. Can be atrophic (age-related or dry) or exudative (wet)
3. Age-related: Caused by gradual blocking of retinal capillaries leading to an ischemic and necrotic macula; rod and cone photoreceptors die.
4. Exudative: Serous detachment of pigment epithelium in the macula occurs; fluid and blood collect under the macula, resulting in scar formation and visual distortion.
5. Interventions are aimed at maximizing the remaining vision.
6. Assessment
   a. A decline in central vision
   b. Blurred vision and distortion
7. Interventions
   a. Initiate strategies to assist in maximizing remaining vision and maintaining independence.
   b. Provide referrals to community organizations.
   c. Laser therapy, photodynamic therapy, or other therapies may be prescribed to seal the leaking blood vessels in or near the macula.

H. Ocular melanoma

1. Most common malignant eye tumor in adults
2. Tumor is usually found in the uveal tract and can spread easily because of the rich blood supply.
3. Assessment
   a. Tumor can be discovered during routine examination.
   b. If the macular area is invaded, blurring of vision occurs.
   c. Increased IOP is present if the canal of Schlemm is invaded.
   d. Change of iris color is noted if the tumor invades the iris.
e. Ultrasonography may be performed to determine tumor size and location.

4. Interventions
a. Surgery: Enucleation
b. Radiation may be given via a radioactive plaque that is sutured to the sclera; the radioactive plaque remains in place until the prescribed radiation dose is delivered.

I. Enucleation and exenteration
1. Description
a. Enucleation is the removal of the entire eyeball.
b. Exenteration is the removal of the eyeball and surrounding tissues and bone.
c. The procedures are performed for the removal of ocular tumors.
d. After the eye is removed, a ball implant is inserted to provide a firm base for a socket prosthesis and to facilitate the best cosmetic result.
e. A prosthesis is fitted about 1 month after surgery.

2. Preoperative interventions
a. Provide emotional support to the client.
b. Encourage the client to verbalize feelings related to loss.
c. Encourage family support in care.

3. Postoperative interventions
a. Monitor vital signs.
b. Assess a pressure patch or dressing as prescribed.
c. Report changes in vital signs or the presence of bright red drainage on the pressure patch or dressing.

J. Hyphema
1. Description: Presence of blood in the anterior chamber that occurs as a result of an injury; usually resolves in 5 to 7 days.
2. Interventions
a. Encourage rest in a semi-Fowler’s position.
b. Avoid sudden eye movements for 3 to 5 days to decrease the likelihood of
bleeding.
c. Administer cycloplegic eye drops as prescribed to relax the eye muscles and place the eye at rest.
d. Instruct the client in the use of eye shields or eye patches as prescribed.
e. Instruct the client to restrict reading and limit watching television.

K. Contusions
1. Description
   a. Bleeding into the soft tissue as a result of an injury.
   b. A contusion causes a black eye; the discoloration disappears in about 10 days.
   c. Pain, photophobia, edema, and diplopia may occur.

2. Interventions
   a. Place ice on the eye immediately.
   b. Instruct the client to receive a thorough eye examination.

L. Foreign bodies
1. Description: An object such as dust or dirt that enters the eye and causes irritation
2. Interventions
   a. Have the client look upward, expose the lower lid, wet a cotton-tipped applicator with sterile normal saline, gently twist the swab over the particle, and remove it.
   b. If the particle cannot be seen, have the client look downward, place a cotton applicator horizontally on the outer surface of the upper eye lid, grasp the lashes, and pull the upper lid outward and over the cotton applicator; if the particle is seen, gently twist a swab over it to remove.

M. Penetrating objects
1. Description: An eye injury in which an object penetrates the eye
2. Interventions
   a. Never remove the object, because it
may be holding ocular structures in place; the object must be removed by the PHCP.
b. Cover the eye with a cup (paper or plastic) and tape in place.
c. Do not allow the client to bend over or lie flat; these positions may move the object.
d. Do not place pressure on the eye.
e. The client is to be seen by the PHCP immediately.
f. X-rays and CT scans of the orbit are usually obtained.
g. MRI is contraindicated because of the possibility of metal-containing projectile movement during the procedure.

N. Chemical burns
1. Description: An eye injury in which a caustic substance enters the eye
2. Interventions (see Priority Nursing Actions)

Priority Nursing Actions

Chemical Eye Injury Interventions in the Emergency Department
1. Quickly assess the client and visual acuity.
2. Check the pH of the eye.
3. Irrigate the eye continuously as prescribed, until the pH is at an acceptable level.
4. Document the event, actions taken, and the client’s response.

Reference

If a chemical splash to the eye occurs, treatment should begin immediately; immediately flush the eyes with water for at least 15 to 20 minutes at the scene of the injury, and then the client is brought to the emergency department. If possible, obtain a sample of the chemical involved.

O. Eye (tissue) donation
1. Donor eyes
   a. Donor eyes are obtained from cadavers.
   b. Donor eyes must be enucleated soon
after death and stored in a preserving solution because of rapid endothelial cell death.

c. Storage, handling, and coordination of donor tissue with surgeons is provided by a network of state and national eye bank associations.

2. Care to the deceased client as a potential eye donor

a. The option of eye donation is discussed with the family.
b. Raise the head of the bed 30 degrees.
c. Instill antibiotic eye drops as prescribed.
d. Close the eyes and apply a small ice pack as prescribed to the closed eyes.

3. Preoperative care to the recipient of the cornea

a. The recipient may be told of the tissue (cornea) availability only several hours to 1 day before the surgery.
b. Assist in alleviating client anxiety.
c. Assess the recipient’s eye for signs of infection.
d. Report the presence of any redness, watery or purulent drainage, or edema around the recipient’s eye to the PHCP.
e. Instill antibiotic drops into the recipient’s eye as prescribed to reduce the number of microorganisms present.
f. Administer fluids and medications intravenously as prescribed.

4. Postoperative care to the recipient

a. The eye is covered with a patch and protective shield that is left in place for 1 day.
b. Do not remove or change the dressing without a PHCP’s prescription.
c. Monitor vital signs.
d. Monitor level of consciousness.
e. Assess the eye dressing.
f. Position the client with the head elevated and on the nonoperative side
to reduce IOP.
g. Orient the client frequently.
h. Monitor for complications of bleeding, wound leakage, infection, and tissue rejection.
i. Instruct the client how to apply a patch and eye shield.
j. Instruct the client to wear the eye shield at night for 1 month and whenever around small children or pets.
k. Advise the client not to rub the eye.
l. Instruct the client to avoid activities that increase IOP.

5. Graft rejection (Fig. 56-3)
   a. Rejection can occur at any time.
   b. Inform the client of the signs of rejection.
   c. Signs include redness, swelling, decreased vision, and pain (RSVP).
   d. The eye is treated with topical corticosteroids.

V. Anatomy and Physiology of the Ear
   A. Functions
      1. Hearing
      2. Maintenance of balance
   B. External ear (pinna)
      1. It is embedded in the temporal bone bilaterally at the level of the eyes.
      2. It extends from the auricle through the external canal to the tympanic membrane or eardrum and includes the mastoid process, the bony ridge located over the temporal bone.
   C. Middle ear
      1. The middle ear consists of the medial side of the tympanic membrane.
      2. It contains 3 bony ossicles.
         a. Malleus
         b. Incus
         c. Stapes
      3. Functions of the middle ear
         a. Conduct sound vibrations from the outer ear to the central hearing apparatus in the inner ear
         b. Protect the inner ear by reducing the amplitude of loud sounds
         c. The auditory canal (eustachian tube) allows equalization of air pressure on
each side of the tympanic membrane so that the membrane does not rupture.

D. Inner ear

1. The inner ear contains the semicircular canals, cochlea, and distal end of the eighth cranial nerve.
2. The semicircular canals contain fluid and hair cells connected to sensory nerve fibers of the vestibular portion of the eighth cranial nerve.
3. The inner ear maintains the sense of balance or equilibrium.
4. The cochlea is the spiral-shaped organ of hearing.
5. The organ of Corti (within the cochlea) is the receptor and organ of hearing.
6. Eighth cranial nerve
   a. The cochlear branch of the nerve transmits neuroimpulses from the cochlea to the brain, where they are interpreted as sound.
   b. The vestibular branch maintains balance and equilibrium.

E. Hearing and equilibrium

1. The external ear conducts sound waves to the middle ear.
2. The middle ear, also called the tympanic cavity, conducts sound waves to the inner ear.
3. The middle ear is filled with air, which is kept at atmospheric pressure by the opening of the auditory canal.
4. The inner ear contains sensory receptors for sound and for equilibrium.
5. The receptors in the inner ear transmit sound waves and changes in body position as nerve impulses.

VI. Assessment of the Ear (see Chapter 12)

VII. Diagnostic Tests for the Ear

A. Tomography

1. Description
   a. Tomography may be performed with or without contrast medium.
   b. Tomography assesses the mastoid, middle ear, and inner ear structures and is especially helpful in the diagnosis of acoustic tumors.
   c. Multiple radiographs of the head are obtained.
2. Interventions
   a. All jewelry is removed.
   b. Lead eye shields are used to cover the cornea to diminish the radiation dose to the eyes.
   c. The client must remain still in a supine position.
   d. No follow-up care is required.
   e. If contrast is to be used, assess for allergies or previous response to contrast.

B. Audiometry
   1. Description
      a. Audiometry measures hearing acuity.
      b. Audiometry uses 2 types, pure tone audiometry and speech audiometry.
      c. Pure tone audiometry is used to identify problems with hearing, speech, music, and other sounds in the environment.
      d. In speech audiometry, the client’s ability to hear spoken words is measured.
      e. After testing, audiographic patterns are depicted on a graph to determine the type and level of the hearing loss.
   2. Interventions
      a. Inform the client regarding the procedure.
      b. Instruct the client to identify the sounds as they are heard.

C. Electronystagmography (ENG)
   1. Description
      a. ENG is a vestibular test that evaluates spontaneous and induced eye movements known as nystagmus.
      b. ENG is used to distinguish between normal nystagmus and medication-induced nystagmus, or nystagmus caused by a lesion in the central or peripheral vestibular pathway.
      c. ENG records changing electrical fields with the movement of the eye, as monitored by electrodes placed on the skin around the eye.
   2. Interventions
      a. The client is instructed to remain NPO
(nothing by mouth) for 3 hours before testing, and to avoid caffeine-containing beverages for 24 to 48 hours before the test.
b. Unnecessary medications are withheld for 24 hours before testing.
c. Instruct the client that this is a long and tiring procedure.
d. The client should bring prescription eyeglasses to the examination.
e. The client sits and is instructed to gaze at lights, focus on a moving pattern, focus on a moving point, and then close the eyes.
f. While sitting in a chair, the client may be rotated to obtain information about vestibular function.
g. In addition, the client’s ears are irrigated with cool and warm water, which may cause nausea and vomiting.
h. Following the procedure, the client begins taking clear fluids slowly and cautiously because nausea and vomiting may occur.
i. Assistance with ambulation may also be necessary following the procedure.

D. MRI: Refer to Chapter 58 for information on MRI.

VIII. Problems of the Ear

A. Risk factors related to ear problems (Box 56-3)

B. Conductive hearing loss (Fig. 56-4)

1. Description
   a. Occurs when sound waves are blocked to the inner ear fibers because of external or middle ear problems
   b. Problems often can be corrected with no damage to hearing or minimal permanent hearing loss.

2. Causes
   a. Any inflammatory process or obstruction of the external or middle ear
   b. Tumors
   c. Otosclerosis
   d. A buildup of scar tissue on the ossicles from previous middle ear surgery

C. Sensorineural hearing loss (see Fig. 56-4)
1. Description
   a. A pathological process of the inner ear or of the sensory fibers that lead to the cerebral cortex
   b. Sensorineural hearing loss is often permanent, and measures must be taken to reduce further damage.

2. Causes
   a. Damage to the inner ear structures
   b. Damage to the eighth cranial nerve or the brain itself
   c. Prolonged exposure to loud noise
   d. Medications
   e. Trauma
   f. Inherited problems
   g. Metabolic and circulatory problems
   h. Infections
   i. Surgery
   j. Meniere’s syndrome
   k. Diabetes mellitus
   l. Myxedema

D. Mixed hearing loss (see Fig. 56-4)
   1. Also known as conductive-sensorineural hearing loss
   2. The client has both sensorineural and conductive hearing loss.

E. Central hearing loss: Involves the inability to interpret sound, including speech, due to a problem in the brain

F. Signs of hearing loss and facilitating communication (Boxes 56-4 and 56-5)

G. Cochlear implantation
   1. Cochlear implants are used for sensorineural hearing loss.
   2. A small computer converts sound waves into electrical impulses.
   3. Electrodes are placed by the internal ear with a computer device attached to the external ear.
   4. Electronic impulses directly stimulate nerve fibers.

H. Hearing aids
   1. Used for the client with conductive hearing loss
   2. Have limited value for the client with sensorineural hearing loss, because they make sounds only louder, not clearer
   3. A difficulty that exists in the use of hearing aids is the amplification of background noise and voices.
   4. Hearing aids are costly and often not covered by insurance. Some clients can obtain hearing aids through a rehabilitation facility or through other
I. Presbycusis

1. Description
   a. A sensorineural hearing loss associated with aging
   b. **Presbycusis** leads to degeneration or atrophy of the ganglion cells in the cochlea and a loss of elasticity of the basilar membranes.
   c. Presbycusis leads to compromise of the vascular supply to the inner ear, with changes in several areas of the ear structure.

2. Assessment
   a. Hearing loss is gradual and bilateral.
   b. Client states that he or she has no problem with hearing but cannot understand what the words are.
   c. Client thinks that the speaker is mumbling.

---

J. Otitis externa: See Chapter 34.
K. Otitis media: See Chapter 34.
   1. Myringotomy: See Chapter 34.
   2. Client education (Box 56-7)

L. Chronic otitis media
   1. Description
      a. A chronic infective, inflammatory, or allergic response involving the structure of the middle ear
      b. Frequent removal of debris from the ear canal may be required.
      c. Myringoplasty can reconstruct the tympanic membrane and ossicles and improve conductive hearing loss.
      d. Mastoidectomy may be performed if the infection has spread to involve the mastoid bone.

---

Instruct the client that cotton-tipped applicators should not be inserted into the ear canal, because their use can lead to trauma to the canal and can puncture the tympanic membrane.
Monitor the client with otitis media closely for response to treatment. Otic and systemic antibiotics may be used to treat the infection, but often the organism is resistant.

2. Preoperative interventions
   a. Administer antibiotic drops as prescribed.
   b. Clean the ear of debris as prescribed; irrigate the ear with a solution of equal parts vinegar and sterile water as prescribed to restore the normal pH of the ear.
   c. Instruct the client to avoid persons with upper respiratory infections, obtain adequate rest, eat a balanced diet, and drink adequate fluids.
   d. Instruct the client in deep breathing and coughing; forceful coughing, which increases pressure in the middle ear, is to be avoided postoperatively.

3. Postoperative interventions
   a. Inform the client that initial hearing after surgery is diminished because of the packing in the ear canal; hearing improvement will occur after the ear canal packing is removed.
   b. Keep the dressing clean and dry.
   c. Keep the client flat as prescribed, with the operative ear up for at least 12 hours.
   d. Administer antibiotics as prescribed.

M. Mastoiditis

1. Description
   a. Mastoiditis may be acute or chronic and results from untreated or inadequately treated chronic or acute otitis media.
   b. The pain is not relieved by myringotomy.

2. Assessment
   a. Swelling behind the ear and pain with minimal movement of the head
   b. Cellulitis on the skin or external scalp over the mastoid process
   c. A reddened, dull, thick, immobile tympanic membrane, with or without
perforation
d. Tender and enlarged postauricular lymph nodes
e. Low-grade fever

3. Interventions
   a. Prepare the client for surgical removal of infected material.
   b. Simple or modified radical mastoidectomy with tympanoplasty is the most common treatment.
   c. Once infected tissue is removed, the tympanoplasty is performed to reconstruct the ossicles and tympanic membrane in an attempt to restore normal hearing.

4. Complications
   a. Damage to the abducens and facial cranial nerves; exhibited by an inability to look laterally (cranial nerve VI, abducens) and a drooping of the mouth on the affected side (cranial nerve VII, facial)
   b. Meningitis
   c. Brain abscess
   d. Chronic purulent otitis media
   e. Wound infections
   f. Vertigo, if the infection spreads into the labyrinth

5. Postoperative interventions
   a. Monitor for dizziness.
   b. Monitor for signs of meningitis, as evidenced by a stiff neck and vomiting, and for other complications.
   c. Prepare for a wound dressing change 24 hours postoperatively.
   d. Monitor the surgical incision for edema, drainage, and redness.
   e. Position the client flat with the operative side up as prescribed.
   f. Restrict the client to bed with bedside commode privileges for 24 hours as prescribed.
   g. Assist the client with getting out of bed to prevent falling or injuries from dizziness.
   h. With reconstruction of the ossicles via a graft, take precautions to prevent dislodging of the graft.
N. Otosclerosis

1. Description

a. A genetic problem of the labyrinthine capsule of the middle ear that results in a bony overgrowth of the tissue surrounding the ossicles.
b. Otosclerosis causes the development of irregular areas of new bone formation and causes the fixation of the bones.
c. Stapes fixation leads to a conductive hearing loss.
d. If the disease involves the inner ear, sensorineural hearing loss is present.
e. Bilateral involvement is common, although hearing loss may be worse in 1 ear.
f. Nonsurgical intervention promotes the improvement of hearing through amplification.
g. Surgical intervention involves removal of the bony growth causing the hearing loss.
h. A partial stapedectomy or complete stapedectomy with prosthesis (fenestration) may be performed surgically.

2. Assessment

a. Slowly progressing conductive hearing loss
b. Bilateral hearing loss
c. A ringing or roaring type of constant tinnitus
d. Loud sounds heard in the ear when chewing
e. Pinkish discoloration (Schwartzte’s sign) of the tympanic membrane, which indicates vascular changes within the ear

O. Fenestration

1. Description

a. Removal of the stapes, with a small hole drilled in the footplate; a prosthesis is connected between the incus and footplate.
b. Sounds cause the prosthesis to vibrate
in the same manner as the stapes.
c. Complications include complete hearing loss, prolonged vertigo, infection, and facial nerve damage.

2. Preoperative interventions
   a. Instruct the client in measures to prevent middle ear or external ear infections.
   b. Instruct the client to avoid excessive nose blowing.

3. Postoperative interventions
   a. Inform the client that hearing is initially worse after the surgical procedure because of swelling, and that no noticeable improvement in hearing may occur for as long as 6 weeks.
   b. Inform the client that the Gelfoam ear packing (if used) interferes with hearing but is used to decrease bleeding.
   c. Assist with ambulating during the first 1 to 2 days after surgery.
   d. Administer antibiotic, antivertiginous, and pain medications as prescribed.
   e. Assess for facial nerve damage, weakness, changes in tactile sensation and taste sensation, vertigo, nausea, and vomiting.
   f. Instruct the client to move the head slowly when changing positions to prevent vertigo.
   g. Instruct the client to avoid persons with upper respiratory infections.
   h. Instruct the client to avoid showering and getting the head and wound wet.
   i. Instruct the client to avoid rapid extreme changes in pressure caused by quick head movements, sneezing, nose blowing, straining, and changes in altitude.
   j. Instruct the client to avoid changes in middle ear pressure, because they could dislodge the graft or prosthesis.

P. Labyrinthitis
1. Description: Infection of the labyrinth that occurs as a complication of acute or chronic otitis media
2. May result from growth of a cholesteatoma, a benign
overgrowth of squamous cell epithelium in the middle ear

3. Assessment
   a. Hearing loss that may be permanent on the affected side
   b. Tinnitus
   c. Spontaneous nystagmus to the affected side
   d. Vertigo
   e. Nausea and vomiting

4. Interventions
   a. Monitor for signs of meningitis, the most common complication, as evidenced by headache, stiff neck, and lethargy.
   b. Administer systemic antibiotics as prescribed.
   c. Advise the client to rest in bed in a darkened room.
   d. Administer antiemetics and antivertiginous medications as prescribed.
   e. Instruct the client that the vertigo subsides as the inflammation resolves.
   f. Instruct the client that balance problems that persist may require gait training through physical therapy.

Q. Meniere’s syndrome

1. Description
   a. Also called endolymphatic hydrops; it refers to dilation of the endolymphatic system by overproduction or decreased reabsorption of endolymphatic fluid.
   b. The syndrome is characterized by tinnitus, unilateral sensorineural hearing loss, and vertigo.
   c. Symptoms occur in attacks and last for several days, and the client becomes totally incapacitated during the attacks.
   d. Initial hearing loss is reversible, but as the frequency of attacks increases, hearing loss becomes permanent.
2. Causes

a. Any factor that increases endolymphatic secretion in the labyrinth
b. Viral and bacterial infections
c. Allergic reactions
d. Biochemical disturbances
e. Vascular disturbance, producing changes in the microcirculation in the labyrinth
f. Long-term stress may be a contributing factor.

3. Assessment

a. Feelings of fullness in the ear
b. Tinnitus, as a continuous low-pitched roar or hummin sound, that is present much of the time but worsens just before and during severe attacks
c. Hearing loss that is worse during an attack
d. Vertigo; that is, a sensation of whirling that might cause the client to fall to the ground
e. Vertigo that is so intense that even while lying down, the client holds the bed or ground in an attempt to prevent the whirling
f. Nausea and vomiting
g. Nystagmus
h. Severe headaches

4. Nonsurgical interventions

a. Prevent injury during vertigo attacks.
b. Provide bed rest in a quiet environment.
c. Provide assistance with walking.
d. Instruct the client to move the head slowly to prevent worsening of the vertigo.
e. Initiate sodium and fluid restrictions as prescribed.
f. Instruct the client to stop smoking.
g. Instruct the client to avoid watching television because the flickering of
lights may exacerbate symptoms.
h. Administer nicotinic acid as prescribed for its vasodilatory effect.
i. Administer antihistamines as prescribed to reduce the production of histamine and the inflammation.
j. Administer antiemetics as prescribed.
k. Administer tranquilizers and sedatives as prescribed to calm the client; allow the client to rest; and control vertigo, nausea, and vomiting.
l. Mild diuretics may be prescribed to decrease endolymph volume.
m. Inform the client about vestibular rehabilitation as prescribed.

5. Surgical interventions
   a. Surgery is performed when medical therapy is ineffective and the functional level of the client has decreased significantly.
   b. Endolymphatic drainage and insertion of a shunt may be an option early in the course of the disease to assist with the drainage of excess fluids.
   c. A resection of the vestibular nerve or total removal of the labyrinth (i.e., a labyrinthectomy) may be performed.

6. Postoperative interventions
   a. Assess packing and dressing on the ear.
   b. Speak to the client on the side of the unaffected ear.
   c. Perform neurological assessments.
   d. Maintain safety.
   e. Assist with ambulating.
   f. Encourage the client to use a bedside commode rather than ambulating to the bathroom.
   g. Administer antivertiginous and antiemetic medications as prescribed.

R. Acoustic neuroma
   1. Description
      a. A benign tumor of the vestibular or acoustic nerve
      b. The tumor may cause damage to hearing and to facial movements and sensations.
      c. Treatment includes surgical removal of
the tumor via craniotomy.
d. Care is taken to preserve the function of the facial nerve.
e. The tumor rarely recurs after surgical removal.
f. Postoperative nursing care is similar to postoperative craniotomy care.

2. Assessment

a. Symptoms usually begin with tinnitus and progress to gradual sensorineural hearing loss.
b. As the tumor enlarges, damage to adjacent cranial nerves occurs.

S. Trauma

1. Description

a. The tympanic membrane has limited stretching ability and gives way under high pressure.
b. Foreign objects placed in the external canal may exert pressure on the tympanic membrane and cause perforation.
c. If the object continues through the canal, the bony structure of the stapes, incus, and malleus may be damaged.
d. A blunt injury to the basal skull and ear can damage the middle ear structures through fractures extending to the middle ear.
e. Excessive nose blowing and rapid changes of pressure that occur with nonpressurized air flights can increase pressure in the middle ear.
f. Depending on the damage to the ossicles, hearing loss may or may not be reversible.

2. Interventions

a. Tympanic membrane perforations usually heal within 24 hours.
b. Surgical reconstruction of the ossicles and tympanic membrane through tympanoplasty or myringoplasty may be performed to improve hearing.

T. Cerumen and foreign bodies
1. Description
   a. Cerumen, or wax, is the most common cause of impacted canals.
   b. Foreign bodies can include vegetables, beads, pencil erasers, insects, and other objects.

2. Assessment
   a. Sensation of fullness in the ear with or without hearing loss
   b. Pain, itching, or bleeding

3. Cerumen
   a. Removal of wax may be done by irrigation.
   b. Irrigation is contraindicated in clients with a history of tympanic membrane perforation or otitis media.
   c. If prescribed to soften cerumen, glycerin or mineral oil is placed in the ear at bedtime; hydrogen peroxide may also be prescribed.
   d. After several days, the ear is irrigated.
   e. The maximum amount of solution that should be used for irrigation is 50 to 70 mL.

   **Important:** Inform the client that ear candles should never be used to remove cerumen. Their use can cause burns and a vacuum effect, causing a perforation in the tympanic membrane.

4. Foreign bodies
   a. With a foreign object of vegetable matter, irrigation is used with care, because this material expands with hydration.
   b. Insects are killed before removal, unless they can be coaxed out by flashlight or a humming noise; lidocaine may be placed in the ear to relieve pain.
   c. Mineral oil or diluted alcohol is instilled to suffocate the insect, which then is removed using ear forceps.
   d. Use a small ear forceps to remove the object; avoid pushing the object farther into the canal and damaging the
Box 56-1

Risk Factors for Eye Problems

- Aging process
- Congenital
- Diabetes mellitus
- Hereditary
- Medications
- Trauma

Box 56-2

Client Education Following Cataract Surgery

- Avoid eye straining.
- Avoid rubbing or placing pressure on the eyes.
- Avoid rapid movements, straining, sneezing, coughing, bending, vomiting, or lifting objects heavier than 5 lb (2.25 kg).
- Take measures to prevent constipation.
- Follow instructions for dressing changes and prescribed eye drops and medications.
- Wipe excess drainage or tearing with a sterile wet cotton ball from the inner to the outer canthus.
- Use an eye shield at bedtime.

FIG. 56-1 The cloudy appearance of a lens affected by cataract. (From Patton, Thibodeau, 2010.)
• If lens implantation is not performed, accommodation is affected and glasses must be worn at all times.

• Cataract glasses act as magnifying glasses and replace central vision only, and objects will appear closer; therefore, the client needs to accommodate, judge distance, and climb stairs carefully.

• Contact lenses provide sharp visual acuity but dexterity is needed to insert them.

• Eye itching and mild discomfort are normal for a few days after the procedure.

• Contact the health care provider about any decrease in vision, severe eye pain, increase in redness, or increase in eye discharge.
FIG. 56-2  The scleral buckling procedure for repair of retinal detachment.

Box 56-3

Risk Factors for Ear Problems

- Aging process
- Infection
- Medications
- Ototoxicity
- Trauma
- Tumors
Anatomy of hearing loss. Hearing loss can be divided into 3 types: (1) conductive (difficulty in the external or the middle ear); (2) sensorineural (difficulty in the inner ear or vestibulocochlear nerve); and (3) mixed conductive-sensorineural (a combination of the two).

**Box 56-4**

**Signs of Hearing Loss**

- Frequently asking others to repeat statements
- Straining to hear
- Turning the head or leaning forward to favor 1 ear
- Shouting in conversation
- Ringing in the ears
- Failing to respond when not looking in the direction of the sound
- Answering questions incorrectly
- Raising the volume of the television or radio
- Avoiding large groups
- Better understanding of speech when in small groups
- Withdrawing from social interactions

**Box 56-5**

1961
Facilitating Communication

- Using written words if the client is able to see, read, and write
- Providing plenty of light in the room
- Getting the attention of the client before beginning to speak
- Facing the client when speaking
- Talking in a room without distracting noises
- Moving close to the client and speaking slowly and clearly
- Keeping hands and other objects away from the mouth when talking to the client
- Talking in normal volume and at a lower pitch because shouting is not helpful and higher frequencies are less easily heard
- Rephrasing sentences and repeating information
- Validating with the client the understanding of statements made by asking the client to repeat what was said
- Reading lips
- Encouraging the client to wear glasses when talking to someone to improve vision for lip reading
- Using sign language, which combines speech with hand movements that signify letters, words, or phrases
- Using telephone amplifiers
- Using flashing lights that are activated by ringing of the telephone or doorbell
- Using specially trained dogs to help the client be aware of sound and alert the client to potential danger

Box 56-6
Client Education Regarding a Hearing Aid

- Begin using the hearing aid slowly to adjust to the device.
- Adjust the volume to the minimal hearing level to prevent feedback squealing.
- Concentrate on the sounds that are to be heard and to filter out background noise.
- Clean the ear mold and cannula per manufacturer’s instructions.
- Keep the hearing aid dry.
- Turn the hearing aid off before removing from the ear to prevent squealing feedback; remove the battery when not in use.
- Keep extra batteries on hand.
- Keep the hearing aid in a safe place.
- Prevent hairsprays, oils, or other hair and face products from coming into contact with the receiver of the hearing aid.
- Instruct the client to keep the hearing aid in the proper environmental climate as
recommended by the manufacturer in order to prolong the life of the device.

Box 56-7
Client Education Following Myringotomy

- Avoid strenuous activities.
- Avoid rapid head movements, bouncing, or bending.
- Avoid straining on bowel movement.
- Avoid drinking through a straw.
- Avoid traveling by air.
- Avoid forceful coughing.
- Avoid contact with persons with colds.
- Avoid washing hair, showering, or getting the head wet for 1 week as prescribed.
- Use proper hand hygiene to prevent infection.
- Instruct the client that if he or she needs to blow the nose, to blow 1 side at a time with the mouth open.
- Instruct the client to keep ears dry by keeping a ball of cotton coated with petroleum jelly in the ear and to change the cotton ball daily.
- Instruct the client to report excessive ear drainage to the primary health care provider.

Practice Questions

676. During the early postoperative period, a client who has undergone a cataract extraction complains of nausea and severe eye pain over the operative site. What should be the initial nursing action?
   1. Call the surgeon.
   2. Reassure the client that this is normal.
   3. Turn the client onto her or his operative side.
   4. Administer the prescribed pain medication and antiemetic.

677. The nurse is developing a teaching plan for a client with glaucoma. Which instruction should the nurse include in the plan of care?
   1. Avoid overuse of the eyes.
   2. Decrease the amount of salt in the diet.
   3. Eye medications will need to be administered for life.
   4. Decrease fluid intake to control the intraocular pressure.

678. The nurse is performing an admission assessment on a client with a diagnosis of detached retina. Which sign or symptom is associated with this eye problem?
   1. Total loss of vision
   2. Pain in the affected eye
3. A yellow discoloration of the sclera
4. A sense of a curtain falling across the field of vision

679. The nurse is performing an otoscopic examination on a client with mastoiditis. On examination of the tympanic membrane, which finding should the nurse expect to observe?
   1. A pink-colored tympanic membrane
   2. A pearly colored tympanic membrane
   3. A transparent and clear tympanic membrane
   4. A red, dull, thick, and immobile tympanic membrane

680. A client is diagnosed with a problem involving the inner ear. Which is the most common client complaint associated with a problem involving this part of the ear?
   1. Pruritus
   2. Tinnitus
   3. Hearing loss
   4. Burning in the ear

681. The nurse is performing an assessment on a client with a suspected diagnosis of cataract. Which clinical manifestation should the nurse expect to note in the early stages of cataract formation?
   1. Diplopia
   2. Eye pain
   3. Floating spots
   4. Blurred vision

682. A client arrives in the emergency department following an automobile crash. The client’s forehead hit the steering wheel, and a hyphema is diagnosed. The nurse should place the client in which position?
   1. Flat in bed
   2. A semi-Fowler’s position
   3. Lateral on the affected side
   4. Lateral on the unaffected side

683. The client sustains a contusion of the eyeball following a traumatic injury with a blunt object. Which intervention should be initiated immediately?
   1. Apply ice to the affected eye.
   2. Irrigate the eye with cool water.
   3. Notify the primary health care provider (PHCP).
   4. Accompany the client to the emergency department.

684. A client arrives in the emergency department with a penetrating eye injury from wood chips that occurred while cutting wood. The nurse assesses the eye and notes a piece of wood protruding from the eye. What is the initial nursing action?
   1. Apply an eye patch.
   2. Perform visual acuity tests.
   3. Irrigate the eye with sterile saline.
   4. Remove the piece of wood using a sterile eye clamp.

685. The nurse is caring for a client following enucleation to treat an ocular tumor and notes the presence of bright red drainage on the dressing. Which action should the nurse take at this time?
   1. Document the finding.
2. Continue to monitor the drainage.
3. Notify the primary health care provider (PHCP).
4. Mark the drainage on the dressing and monitor for any increase in bleeding.

686. A woman was working in her garden. She accidentally sprayed insecticide into her right eye. She calls the emergency department, frantic and screaming for help. The nurse should instruct the woman to take which immediate action?
   1. Irrigate the eyes with water.
   2. Come to the emergency department.
   3. Call the primary health care provider (PHCP).
   4. Irrigate the eyes with diluted hydrogen peroxide.

687. The nurse is preparing a teaching plan for a client who had a cataract extraction with intraocular implantation. Which home care measures should the nurse include in the plan? Select all that apply.
   1. Avoid activities that require bending over.
   2. Contact the surgeon if eye scratchiness occurs.
   3. Take acetaminophen for minor eye discomfort.
   4. Expect episodes of sudden severe pain in the eye.
   5. Place an eye shield on the surgical eye at bedtime.
   6. Contact the surgeon if a decrease in visual acuity occurs.

688. Tonometry is performed on a client with a suspected diagnosis of glaucoma. The nurse looks at the documented test results and notes an intraocular pressure (IOP) value of 23. What should be the nurse’s initial action?
   1. Apply normal saline drops.
   2. Note the time of day the test was done.
   3. Contact the primary health care provider (PHCP).
   4. Instruct the client to sleep with the head of the bed flat.

689. The nurse is caring for a client following craniotomy for removal of an acoustic neuroma. Assessment of which cranial nerve would identify a complication specifically associated with this surgery?
   1. Cranial nerve I, olfactory
   2. Cranial nerve IV, trochlear
   3. Cranial nerve III, oculomotor
   4. Cranial nerve VII, facial nerve

690. The nurse notes that the primary health care provider has documented a diagnosis of presbycusis on a client’s chart. Based on this information, what action should the nurse take?
   1. Speak loudly but mumble or slur the words.
   2. Speak loudly and clearly while facing the client.
   3. Speak at normal tone and pitch, slowly and clearly.
   4. Speak loudly and directly into the client’s affected ear.

691. A client with Meniere’s disease is experiencing severe vertigo. Which instruction should the nurse give to the client to assist in controlling the
vertigo?
1. Increase sodium in the diet.
2. Avoid sudden head movements.
3. Lie still and watch the television.
4. Increase fluid intake to 3000 mL a day.

692. The nurse is preparing to test the visual acuity of a client, using a Snellen chart. Which identifies the accurate procedure for this visual acuity test?
1. The right eye is tested, followed by the left eye, and then both eyes are tested.
2. Both eyes are assessed together, followed by an assessment of the right eye and then the left eye.
3. The client is asked to stand at a distance of 40 feet (12 meters) from the chart and to read the largest line on the chart.
4. The client is asked to stand at a distance of 40 feet (12 meters) from the chart and to read the line that can be read 200 feet (60 meters) away by an individual with unimpaired vision.

693. A client’s vision is tested with a Snellen chart. The results of the tests are documented as 20/60. What action should the nurse implement based on this finding?
1. Provide the client with materials on legal blindness.
2. Instruct the client that he or she may need glasses when driving.
3. Inform the client of where he or she can purchase a white cane with a red tip.
4. Inform the client that it is best to sit near the back of the room when attending lectures.

694. The nurse is caring for a hearing-impaired client. Which approach will facilitate communication?
1. Speak loudly.
2. Speak frequently.
3. Speak at a normal volume.
4. Speak directly into the impaired ear.

Answers

676. Answer: 1

Rationale: Severe pain or pain accompanied by nausea following a cataract extraction is an indicator of increased intraocular pressure and should be reported to the surgeon immediately. Options 2, 3, and 4 are inappropriate actions.

Test-Taking Strategy: Note the strategic word, initial, and the word severe. Eliminate option 2 because this is not a normal condition. The client should not be turned to the operative side; therefore, eliminate option 3. From the remaining options, focusing on the strategic word will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation

Priority Concepts: Clinical Judgment; Pain

677. Answer: 3

Rationale: The administration of eye drops is a critical component of the treatment plan for the client with glaucoma. The client needs to be instructed that medications will need to be taken for the rest of her or his life. Options 1, 2, and 4 are not accurate instructions.

Test-Taking Strategy: Focus on the subject, client teaching for glaucoma. Recalling that medications are an integral component of the treatment plan will assist in directing you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Adult Health: Eye
Health Problem: Adult Health: Eye: Glaucoma
Priority Concepts: Client Education; Sensory Perception

678. Answer: 4

Rationale: A characteristic manifestation of retinal detachment described by the client is the feeling that a shadow or curtain is falling across the field of vision. No pain is associated with detachment of the retina. Options 1 and 3 are not characteristics of this problem. A retinal detachment is an ophthalmic emergency, and even more so if visual acuity is still normal.

Test-Taking Strategy: Focus on the subject, manifestations of retinal detachment. Thinking about the pathophysiology associated with this problem will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Eye
Health Problem: Adult Health: Eye: Retinal Detachment
Priority Concepts: Clinical Judgment; Sensory Perception

679. Answer: 4

Rationale: Otoscopic examination in a client with mastoiditis reveals a red, dull, thick, and immobile tympanic membrane, with or without perforation. Postauricular lymph nodes are tender and enlarged. Clients also have a low-grade fever, malaise, anorexia, swelling behind the ear, and pain with minimal movement of the head.

Test-Taking Strategy: Focus on the subject, the assessment findings in mastoiditis. Think about the pathophysiology associated with mastoiditis and remember that
mastoiditis reveals a red, dull, thick, and immobile tympanic membrane.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Ear

**Health Problem:** Adult Health: Ear: Inflammatory/Infections/Structural Problems

**Priority Concepts:** Infection; Inflammation

**Reference:** Lewis et al. (2017), pp. 384-385.

680. **Answer:** 2

**Rationale:** Tinnitus is the most common complaint of clients with otological problems, especially problems involving the inner ear. Symptoms of tinnitus range from mild ringing in the ear, which can go unnoticed during the day, to a loud roaring in the ear, which can interfere with the client’s thinking process and attention span. Options 1, 3, and 4 are not associated specifically with problems of the inner ear.

**Test-Taking Strategy:** Note the strategic word, most. Recalling the anatomy and the function of the inner ear will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Ear

**Health Problem:** Adult Health: Ear: Vertigo/Tinnitus

**Priority Concepts:** Clinical Judgment; Sensory Perception

681. **Answer:** 4

**Rationale:** A gradual, painless blurring of central vision is the chief clinical manifestation of a cataract. Early symptoms include slightly blurred vision and a decrease in color perception. Options 1, 2, and 3 are not characteristics of a cataract.

**Test-Taking Strategy:** Note the strategic word, early. Remember the pathophysiology related to cataract development. As a cataract develops, the lens of the eye becomes opaque. This description will assist in directing you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Eye

**Health Problem:** Adult Health: Eye: Cataracts

**Priority Concepts:** Clinical Judgment; Sensory Perception

682. **Answer:** 2

**Rationale:** A hyphema is the presence of blood in the anterior chamber. Hyphema
is produced when a force is sufficient to break the integrity of the blood vessels in
the eye and can be caused by direct injury, such as a penetrating injury from a BB or
pellet, or indirectly, such as from striking the forehead on a steering wheel during an
accident. The client is treated by bed rest in a semi-Fowler’s position to assist gravity
in keeping the hyphema away from the optical center of the cornea.

**Test-Taking Strategy:** Focus on the **subject**, care of the client who has sustained a
hyphema. Remember that placing the client flat will produce an increase in pressure
at the injured site. Also, note that the correct option is the one that identifies a
position different from the other options.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Complex Care: Emergency Situations/Management

**Health Problem:** Adult Health: Eye: Inflammation/Infections/Injuries

**Priority Concepts:** Safety; Tissue Integrity

683. **Answer:** 1

**Rationale:** Treatment for a contusion begins at the time of injury. Ice is applied
immediately. The client then should be seen by a PHCP and receive a thorough eye
examination to rule out the presence of other eye injuries.

**Test-Taking Strategy:** Focus on the **strategic word**, immediately. Recalling the
principles related to initial treatment of injuries and noting the type of injury
sustained will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Complex Care: Emergency Situations/Management

**Health Problem:** Adult Health: Eye: Inflammation/Infections/Injuries

**Priority Concepts:** Clinical Judgment; Tissue Integrity

684. **Answer:** 2

**Rationale:** If the eye injury is the result of a penetrating object, the object may be
noted protruding from the eye. This object must never be removed except by the
ophthalmologist, because it may be holding ocular structures in place. Application of
an eye patch or irrigation of the eye may disrupt the foreign body and cause further
tearing of the cornea.

**Test-Taking Strategy:** Note the **strategic word**, initial, and note the word
penetrating. This should indicate that a laceration has occurred and that interventions
are directed at preventing further disruption of the integrity of the eye. The only
option that will prevent further disruption is to assess visual acuity.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation
685. Answer: 3

Rationale: If the nurse notes the presence of bright red drainage on the dressing, it must be reported to the PHCP, because this indicates hemorrhage. Options 1, 2, and 4 are inappropriate at this time.

Test-Taking Strategy: Determine if an abnormality exists. Note the words, bright red. Since an abnormality does exist, eliminate options that state to document and continue to monitor because an action is needed.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Complex Care: Emergency Situations/Management
Health Problem: Adult Health: Eye: Inflammation/Infections/Injuries
Priority Concepts: Clinical Judgment; Tissue Integrity

686. Answer: 1

Rationale: In this type of accident, the client is instructed to irrigate the eyes immediately with running water for at least 20 minutes, or until the emergency medical services personnel arrive. In the emergency department, the cleansing agent of choice is usually normal saline. Calling the PHCP and going to the emergency department delays necessary intervention. Hydrogen peroxide is never placed in the eyes.

Test-Taking Strategy: Note the strategic word, immediate. Focus on the type of injury and eliminate options 2 and 3 because they delay necessary intervention. Next, eliminate option 4 because hydrogen peroxide is never placed in the eyes.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Complex Care: Emergency Situations/Management
Health Problem: Adult Health: Eye: Ocular tumors, retinoblastoma
Priority Concepts: Clinical Judgment; Tissue Integrity

687. Answer: 1, 3, 5, 6

Rationale: Following eye surgery, some scratchiness and mild eye discomfort may occur in the operative eye and usually is relieved by mild analgesics. If the eye pain becomes severe, the client should notify the surgeon, because this may indicate hemorrhage, infection, or increased intraocular pressure (IOP). The nurse also would instruct the client to notify the surgeon of increased purulent drainage, increased
redness, or any decrease in visual acuity. The client is instructed to place an eye shield over the operative eye at bedtime to protect the eye from injury during sleep and to avoid activities that increase IOP, such as bending over.

**Test-Taking Strategy:** Focus on the **subject**, postoperative care following eye surgery. Recalling that the eye needs to be protected and that increased IOP is a concern will assist in determining the home care measures to be included in the plan.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Adult Health: Eye

**Health Problem:** Adult Health: Eye: Cataracts

**Priority Concepts:** Client Education; Safety

**Reference:** Lewis et al. (2017), p. 376.

688. **Answer:** 2

**Rationale:** Tonometry is a method of measuring intraocular fluid pressure. Pressures between 10 and 21 mm Hg are considered within the normal range. However, IOP is slightly higher in the morning. Therefore, the initial action is to check the time the test was performed. Normal saline drops are not a specific treatment for glaucoma. It is not necessary to contact the PHCP as an initial action. Flat positions may increase the pressure.

**Test-Taking Strategy:** Focus on the **subject**, normal IOP, and note the **strategic word**, initial. Remember that normal IOP is between 10 and 21 mm Hg and the pressure may be higher in the morning.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Adult Health: Eye

**Health Problem:** Adult Health: Eye: Glaucoma

**Priority Concepts:** Clinical Judgment; Sensory Perception

689. **Answer:** 4

**Rationale:** An acoustic neuroma (or vestibular schwannoma) is a unilateral benign tumor that occurs where the vestibulocochlear or acoustic nerve (cranial nerve VIII) enters the internal auditory canal. It is important that an early diagnosis be made, because the tumor can compress the trigeminal and facial nerves and arteries within the internal auditory canal. Treatment for acoustic neuroma is surgical removal via a craniotomy. Assessment of the trigeminal and facial nerves is important. Extreme care is taken to preserve remaining hearing and preserve the function of the facial nerve. Acoustic neuromas rarely recur following surgical removal.

**Test-Taking Strategy:** Focus on the **subject**, a complication following surgery. Think about the anatomical location of an acoustic neuroma and the nerves that the neuroma can compress to direct you to the correct option.

**Level of Cognitive Ability:** Analyzing
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Ear  
**Health Problem:** Adult Health: Ear: Hearing Loss  
**Priority Concepts:** Clinical Judgment; Sensory Perception  

690. **Answer:** 3

**Rationale:** Presbycusis is a type of hearing loss that occurs with aging. Presbycusis is a gradual sensorineural loss caused by nerve degeneration in the inner ear or auditory nerve. When communicating with a client with this condition, the nurse should speak at a normal tone and pitch, slowly and clearly. It is not appropriate to speak loudly, mumble or slur words, or speak into the client’s affected ear.  
**Test-Taking Strategy:** Focus on the **subject**, presbycusis and the effective method to communicate. Visualize each of the communication techniques to direct you to the correct option.  
**Level of Cognitive Ability:** Applying

---

691. **Answer:** 2

**Rationale:** The nurse instructs the client to make slow head movements to prevent worsening of the vertigo. Dietary changes such as salt and fluid restrictions that reduce the amount of endolymphatic fluid are sometimes prescribed. Lying still and watching television will not control vertigo.  
**Test-Taking Strategy:** Focus on the **subject**, preventing vertigo. Note the relationship between vertigo and avoiding sudden head movements in the correct option.  
**Level of Cognitive Ability:** Applying

---

692. **Answer:** 1

**Rationale:** Visual acuity is assessed in 1 eye at a time, and then in both eyes together, with the client comfortably standing or sitting. The right eye is tested with the left eye covered; then the left eye is tested with the right eye covered. Both eyes
are then tested together. Visual acuity is measured with or without corrective lenses, and the client stands at a distance of 20 feet (6 meters) from the chart.

**Test-Taking Strategy:** Remember that normal visual acuity as measured by a Snellen chart is 20/20 vision. This should assist in eliminating options 3 and 4, because they are **comparable or alike** in that they indicate standing at a distance of 40 feet (12 meters). From the remaining options, remember that it is best and most accurate to test each eye separately and then test both eyes together.

**Level of Cognitive Ability:** Applying

**Client Needs:** Health Promotion and Maintenance

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Health Assessment/Physical Exam: Eye

**Health Problem:** N/A

**Priority Concepts:** Clinical Judgment; Sensory Perception

693. **Answer:** 2

**Rationale:** Vision that is 20/20 is normal—that is, the client is able to read from 20 feet (6 meters) what a person with normal vision can read from 20 feet (6 meters). A client with a visual acuity of 20/60 can only read at a distance of 20 feet (6 meters) what a person with normal vision can read at 60 feet (18 meters). With this vision, the client may need glasses while driving in order to read signs and to see far ahead. The client should be instructed to sit in the front of the room for lectures to aid in visualization. This is not considered to be legal blindness.

**Test-Taking Strategy:** Focus on the **subject**, interpreting a Snellen chart result. Note the test result, 20/60, and recall the associated interventions for this result. Also, eliminate options 1 and 3, as they are **comparable or alike**, implying that the test results indicate blindness.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Adult Health: Health Assessment/Physical Exam: Eye

**Health Problem:** Adult Health: Eye: Visual problems/refractive errors

**Priority Concepts:** Clinical Judgment; Sensory Perception

**Reference:** Lewis et al. (2017), p. 356.

694. **Answer:** 3

**Rationale:** Speaking in a normal tone to the client with impaired hearing and not shouting are important. The nurse should talk directly to the client while facing the client and speak clearly. If the client does not seem to understand what is said, the nurse should express it differently. Moving closer to the client and toward the better ear may facilitate communication, but the nurse should avoid talking directly into the impaired ear.

**Test-Taking Strategy:** Focus on the **subject**, an effective communication technique for the hearing impaired. Remember that it is important to speak in a normal tone.

**Level of Cognitive Ability:** Applying
Client Needs: Psychosocial Integrity

CHAPTER 57

Eye and Ear Medications

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Safety; Sensory Perception

I. Ophthalmic Medication Administration

A. Guidelines for the use of eye medications

1. Eye medications are usually in the form of drops or ointments.
2. To prevent overflow of medication into the nasal and pharyngeal passages, thus reducing systemic absorption, instruct the client to apply pressure over the inner canthus next to the nose for 30 to 60 seconds following administration of the medication; instruct the client to close the eye gently to help distribute the medication (Fig. 57-1).
3. If both an eye drop and eye ointment are scheduled to be administered at the same time, administer the eye drop first.
4. Wash hands and don gloves before administering eye medications to avoid contaminating the eye or medication dropper or applicator.
5. Use a separate bottle or tube of medication for each client to avoid accidental cross-contamination.
6. Place the prescribed dose of eye medication in the lower conjunctival sac, never directly onto the cornea.
7. Avoid touching any part of the eye with the dropper or applicator.
8. Administer glucocorticoid preparations before other medications.
9. Monitor the pulse and blood pressure if the client is receiving an ophthalmic beta blocker, and instruct the client to do the same; the nurse should obtain pulse parameters from the primary health care provider (PHCP).
10. Instruct the client how to instill medication correctly and supervise instillation until the client can do it.
safely; adaptive devices that position the bottle of eye drops directly over the eye can also be purchased if instillation is difficult for the client.

11. Instruct the client to read the medication labels carefully to ensure administration of the correct medication and correct strength.

12. Remind the client to keep these medications out of the reach of children.

13. Instruct the client to avoid driving or operating hazardous equipment if vision is blurred.

14. Inform the client that she or he may be unable to drive home after eye examinations when a medication to dilate the pupil (mydriatic) or to paralyze the ciliary muscle (cycloplegic) is used.

15. If photophobia occurs, instruct the client to wear sunglasses and avoid bright lights.

16. Instruct the client to administer a missed dose of the eye medication as soon as it is remembered, unless the next dose is scheduled to be administered in 1 to 2 hours.

17. Inform the client with glaucoma that the disorder cannot be cured, only controlled.

18. Reinforce the importance of using medications to treat glaucoma as prescribed and not to discontinue these medications without consulting the PHCP.

19. Inform the client that medications used to treat glaucoma may cause pain and blurred vision, especially when therapy is begun.

20. Instruct the client to report the development of any eye irritation.

21. Inform the client using eye gel to store the gel at room temperature or in the refrigerator, but not to freeze it.

22. Instruct the client to discard unused eye gel kept at room temperature as recommended by the PHCP and/or the pharmacist.

23. Inform the client that soft contact lenses may absorb certain eye medications and that preservatives in eye medications may discolor the contact lenses.

24. Advise the client wearing contact lenses to question the PHCP carefully about special precautions to observe with eye medications.

25. Inform the parents of infants that atropine sulfate eye drops may contribute to abdominal distention.

26. Instruct the parents to keep a record of the infant’s bowel movements if atropine sulfate eye drops are being administered.

27. Auscultate bowel sounds of the infant or child receiving atropine sulfate eye drops.
Because the timing of medication administration is critical, administer eye medications at precise intervals as prescribed; separate the instillation by 3 to 5 minutes if two medications must be administered at the same time.

B. Instillation of eye medications

1. Drops
   a. Wash hands.
   b. Put gloves on.
   c. Check the name, strength, and expiration date of the medication.
   d. Instruct the client to tilt the head backward, open the eyes, and look up.
   e. Pull the lower lid down against the cheekbone.
   f. Hold the bottle like a pencil, with the tip downward.
   g. Holding the bottle, gently rest the wrist of the hand on the client’s cheek.
   h. Squeeze the bottle gently to allow the drop to fall into the conjunctival sac.
   i. Instruct the client to close the eyes gently and not to squeeze the eyes shut.
   j. Wait 3 to 5 minutes before instilling another drop, if more than one drop is prescribed, to promote maximal absorption of the medication.
   k. Do not allow the medication bottle, dropper, or applicator to come into contact with the eyelid or conjunctival sac.
   l. To prevent systemic absorption of the medication, apply gentle pressure with a clean tissue to the client’s nasolacrimal duct for 30 to 60 seconds (see Fig. 57-1).

2. Ointments
   a. Instruct the client to lie down or tilt the head backward and look up.
   b. Hold the ointment tube near but not touching, the eye or eyelashes. This action prevents the spread of contaminants from 1 eye to the other.
   c. Squeeze a thin ribbon of ointment along the lining of the lower conjunctival sac, from the inner to the outer canthus.
d. Instruct the client to close the eyes gently, rolling the eyeball in all directions (increases contact area of medication to eye).
e. Instruct the client that vision may be blurred by the ointment.
f. If possible, apply ointment just before bedtime.

II. Mydriatic, Cycloplegic, and Anticholinergic Medications (Box 57-1)

A. Description

1. Mydriatics and cycloplegics dilate the pupils (mydriasis) and relax the ciliary muscles (cycloplegia).
2. Anticholinergics block responses of the sphincter muscle in the ciliary body, producing mydriasis and cycloplegia.
3. These medications are used preoperatively or for eye examinations to produce mydriasis.
4. Mydriatics are contraindicated in glaucoma, cardiac dysrhythmias, and cerebral atherosclerosis and should be used with caution in the older client and in clients with prostatic hypertrophy, diabetes mellitus, or parkinsonism.

B. Side and adverse effects

1. Tachycardia
2. Photophobia
3. Conjunctivitis
4. Dermatitis
5. Elevated blood pressure

C. Atropine toxicity

1. Dry mouth
2. Blurred vision
3. Photophobia
4. Tachycardia
5. Fever
6. Urinary retention
7. Constipation
8. Headache, brow pain
9. Worsening of glaucoma
10. Confusion
11. Hallucinations, delirium
12. Coma

D. Systemic reactions to anticholinergics

1. Dry mouth and skin
2. Fever
3. Thirst
4. Hyperactivity
5. Confusion

E. Interventions

1. Monitor for allergic response.
3. Assess for constipation and urinary retention.
4. Instruct the client that a burning sensation may occur on instillation.
5. Instruct the client not to drive or perform hazardous activities for 24 hours after instillation of the medication unless otherwise directed by the PHCP.
6. Instruct the client to wear sunglasses until the effects of the medication wear off.
7. Instruct the client to notify the PHCP if blurring of vision, loss of sight, difficulty breathing, sweating, or flushing occurs.
8. Instruct the client to report eye pain to the PHCP.

Mydriatics are contraindicated in clients with glaucoma because of the risk of increased intraocular pressure.

III. Anti-infective Eye Medications (Box 57-2)

A. Description: Anti-infective medications kill or inhibit the growth of bacteria, fungi, and viruses.
B. Side and adverse effects
   1. Superinfection
   2. Global irritation
C. Interventions
   1. Assess for risk of injury.
   2. Instruct the client how to apply the eye medication; remind the client to clean exudates from the eyes before administering the medication.
   3. Reinforce the importance of completing the prescribed medication regimen.
   4. Instruct the client to wash the hands thoroughly and frequently.
   5. Advise the client to notify the PHCP if improvement does not occur.

IV. Antiinflammatory Eye Medications (Box 57-3)

A. Description
   1. Antiinflammatory medications control inflammation, thereby reducing vision loss and scarring.
   2. Antiinflammatory medications are used for uveitis, allergic conditions, and inflammation of the conjunctiva, cornea, and lids.
B. Side and adverse effects
1. **Cataracts**
2. Increased intraocular pressure
3. Impaired healing
4. Masking signs and symptoms of infection

C. Interventions
1. Interventions are the same as for anti-infective medications.
2. Note that dexamethasone should not be used for eye abrasions and wounds.

V. Topical Eye Anesthetics
A. Description
1. Topical anesthetics produce corneal anesthesia.
2. Topical anesthetics are used for anesthesia for eye examinations and surgery or to remove foreign bodies from the eye.
3. Do not use the solution if it is discolored, and store the bottle tightly closed.
4. An example is tetracaine.

B. Side and adverse effects
1. Temporary stinging or burning of the eye
2. Temporary loss of corneal reflex

C. Interventions
1. Assess for risk of injury.
2. Note that the medications should not be given to the client for home use and are not to be self-administered by the client.
3. Instruct the client not to rub or touch the eye while it is anesthetized.
4. Note that the blink reflex is lost temporarily and that the corneal epithelium needs to be protected.
5. Provide an eye patch to protect the eye from injury until the corneal reflex returns.

VI. Eye Lubricants (Box 57-4)
A. Description
1. Eye lubricants replace tears or add moisture to the eyes.
2. Eye lubricants moisten contact lenses or an artificial eye and protect the eyes during surgery or diagnostic procedures.
3. Eye lubricants are used for keratitis, during anesthesia, or for a client who is unconscious or has decreased blinking.

B. Side and adverse effects
1. Burning on instillation
2. Discomfort or pain on instillation
3. Allergic reaction

C. Interventions
1. Inform the client that burning may occur on instillation.
2. Be alert to allergic responses to the preservatives in the lubricants.

VII. Medications to Treat Glaucoma (Box 57-5)

A. Description
1. These medications reduce intraocular pressure by constricting the pupil and contracting the ciliary muscle, thereby increasing the blood flow to the retina and decreasing retinal damage and loss of vision.
2. These medications open the anterior chamber angle and increase the outflow of aqueous humor.
3. Some may be used to achieve miosis during eye surgery.
4. Contraindicated in clients with retinal detachment, adhesions between the iris and lens, or inflammatory diseases.
5. Use with caution in clients with asthma, hypertension, corneal abrasion, hyperthyroidism, coronary vascular disease, urinary tract obstruction, gastrointestinal obstruction, ulcer disease, parkinsonism, and bradycardia.

B. Side effects
1. Myopia
2. Headache
3. Eye pain
4. Decreased vision in poor light
5. Local irritation

C. Adverse effects
1. Flushing
2. Diaphoresis
3. Gastrointestinal upset and diarrhea
4. Frequent urination
5. Increased salivation
6. Muscle weakness
7. Respiratory difficulty

D. Toxicity
1. Vertigo and syncope
2. Bradycardia or other dysrhythmias
3. Hypotension
4. Tremors
5. Seizures

E. Interventions
1. Assess vital signs.
3. Assess the client for the degree of diminished vision.
4. Monitor for side and adverse effects and toxic effects.
5. Monitor for postural hypotension, and instruct the client to change positions slowly.
6. Assess breath sounds for wheezes and rhonchi, because some medications can cause bronchospasms and increased bronchial secretions.
7. Maintain oral hygiene because of the increase in salivation.
8. Have atropine sulfate available as an antidote for pilocarpine.
9. Instruct the client or family regarding the correct administration of eye medications.
10. Instruct the client not to stop the medication suddenly.
11. Instruct the client to avoid activities such as driving while vision is impaired.

Instruct the client with glaucoma to read labels on over-the-counter medications and to avoid atropine-like medications, because atropine will increase intraocular pressure.

VIII. β-Adrenergic Blocker Eye Medications (see Box 57-5)

A. Description

1. These medications reduce intraocular pressure by decreasing sympathetic impulses and decreasing aqueous humor production without affecting accommodation or pupil size.
2. These medications are used to treat glaucoma.
3. These medications are contraindicated in the client with asthma or chronic obstructive pulmonary disease, because systemic absorption can cause increased airway resistance.
4. Use these medications with caution in the client receiving oral beta blockers.

B. Side and adverse effects

1. Ocular irritation
2. Visual disturbances
3. Bradycardia
4. Hypotension
5. Bronchospasm

C. Interventions

1. Monitor vital signs, especially blood pressure and pulse, before administering medication.
2. Usually if the pulse is 60 beats per minute or less or if the systolic blood pressure is less than 90 mm Hg, the medication is withheld and the PHCP is contacted. The nurse should obtain pulse parameters from the PHCP for clients receiving ophthalmic beta blockers.
3. Monitor for shortness of breath.
5. Monitor intake and output.
6. Instruct the client to notify the PHCP if shortness of breath occurs.
7. Instruct the client not to discontinue the medication abruptly.
8. Instruct the client to change positions slowly because of the potential for orthostatic hypotension.
9. Instruct the client to avoid hazardous activities.
10. Instruct the client to avoid over-the-counter medications without the PHCP’s approval.
11. Instruct clients with diabetes mellitus using β-adrenergic blockers to monitor blood glucose levels frequently.

IX. Carbonic Anhydrase Inhibitors (see Box 57-5)

A. Description
1. Carbonic anhydrase inhibitors interfere with the production of carbonic acid, which leads to decreased aqueous humor formation and decreased intraocular pressure.
2. These medications are used for the long-term treatment of glaucoma.
3. These medications are contraindicated in the client allergic to sulfonamides.
4. Use with caution for clients with severe renal or liver disease.

B. Side and adverse effects
1. Appetite loss
2. Gastrointestinal upset
3. Paresthesias in the fingers, toes, and face
4. Polyuria
5. Hypokalemia
6. Renal calculi
7. Photosensitivity
8. Lethargy and drowsiness
9. Depression

C. Interventions
1. Monitor vital signs.
2. Assess visual acuity.
3. Assess for risk of injury.
4. Monitor intake and output.
5. Monitor weight.
7. Monitor for side effects such as lethargy, anorexia, drowsiness, polyuria, nausea, and vomiting.
8. Monitor electrolyte levels for hypokalemia.
9. Increase fluid intake unless contraindicated.
10. Advise the client to avoid prolonged exposure to sunlight.
11. Encourage the use of artificial tears for dry eyes.
12. Instruct the client not to discontinue the medication abruptly.
13. Instruct the client to avoid hazardous activities while vision is impaired.
14. Teach the client not to wear contact lenses during or within 15 minutes of instilling these medications.

X. Ocusert System
   A. Description
   1. A thin eye wafer (disk) is impregnated with a time-release dose of pilocarpine.
   2. The Ocusert system was devised to overcome the need for frequent instillation of pilocarpine.
   3. It is placed in the upper or lower cul-de-sac of the eye.
   4. The pilocarpine is released over 1 week.
   5. The disk is replaced every 7 days.
   6. Drawbacks of its use include sudden leakage of pilocarpine, migration of the system over the cornea, and unnoticed loss of the system.

   B. Interventions
   1. Assess the client’s ability to insert the medication disk.
   2. Store the medication in the refrigerator.
   3. Instruct the client to discard damaged or contaminated disks.
   4. Inform the client that temporary stinging is expected but to notify the PHCP if blurred vision or brow pain occurs.
   5. Instruct the client to check for the presence of the disk in the upper or lower cul-de-sac daily at bedtime and on arising.
   6. Because vision may change in the first few hours after the eye system is inserted, instruct the client to replace the disk at bedtime.

XI. Osmotic Medications
   A. Description
   1. Osmotic medications lower intraocular pressure; an example is mannitol.
   2. They are used in emergency treatment of glaucoma and are used preoperatively and postoperatively to
decrease vitreous humor volume.

B. Side and adverse effects
   1. Headache
   2. Nausea, vomiting, diarrhea, dehydration
   3. Disorientation
   4. Electrolyte imbalances

C. Interventions
   1. Assess vital signs.
   2. Assess visual acuity.
   3. Assess for risk of injury.
   4. Monitor intake and output.
   5. Monitor weight.
   7. Increase fluid intake unless contraindicated.
   8. Monitor for changes in level of orientation.

XII. Medications to Treat Macular Degeneration
   A. Pegaptanib, ranibizumab, bevacizumab, aflibercept, verteporfin
   B. Description
      1. Age-related macular degeneration (ARMD) can be dry ARMD (atrophic) or wet ARMD (neovascular).
      2. Dry ARMD is more common; macular photoreceptors undergo gradual breakdown, leading to gradual blurring of central vision.
      3. Wet ARMD progresses faster, and macular degeneration is caused by the growth of new subretinal blood vessels, which leads to fluid leakage that lifts the macula and causes permanent injury.
      4. Characterized by the presence of drusen (yellow deposits under the retina).
   C. Side and adverse effects
      1. Endophthalmitis (eye inflammation caused by bacterial, viral, or fungal infection)
      2. Blurred vision
      3. Cataracts
      4. Corneal edema
      5. Eye discomfort and discharge
      6. Conjunctival hemorrhage
      7. Increased intraocular pressure
      8. Reduced visual acuity
   D. Interventions
      1. Teach the client about administration of the medications.
      2. Teach the client about the side effects and the need to notify the PHCP.

XIII. Otic Medication Administration
A. Instillation of ear drops

1. In an adult, pull the pinna up and back to straighten the external canal to instill ear drops.
2. Tilt the client’s head in the opposite direction of the affected ear and apply the drops into the ear.
3. With the head tilted, gently move the head back and forth 5 times.
4. Pull the pinna down and back for infants and children younger than 3 years, up and back for older children.

B. Irrigation of the ear (Fig. 57-2)

1. Irrigation of the ear needs to be prescribed by the PHCP.
2. Ensure direct visualization of the tympanic membrane.
3. Warm the irrigating solution to 98.6°F (37.0°C), because a solution temperature that is not close to the client’s body temperature will cause ear injury, nausea, vertigo, and nystagmus.
4. Irrigation must be done gently to avoid damage to the eardrum.
5. When irrigating, to prevent injury, do not direct irrigation solution directly toward the eardrum but rather toward the wall of the ear canal. In addition, to remove cerumen, the solution is directed above or below the impaction toward the wall of the canal to allow back pressure to push the impaction out.
6. During irrigation, the client should be positioned with the ear to be irrigated facing up. Fall precautions should be instituted, because the client may get dizzy, and an emesis basin should be available, because vomiting can occur.

C. Systemic medications that affect hearing (Box 57-6)

If a perforation of the eardrum is suspected, do not perform ear irrigation.

XIV. Anti-infective Ear Medications (Box 57-7)

A. Description

1. Anti-infective medications kill or inhibit the growth of bacteria and are used for otitis media or otitis externa.
2. These medications are contraindicated if a prior hypersensitivity exists.

B. Side and adverse effect: Overgrowth of nonsusceptible organisms

C. Interventions

1. Monitor vital signs.
3. Assess for pain.
4. Monitor for signs of secondary infection.
5. Instruct the client to report dizziness, fatigue, fever, or sore throat, which may indicate a superimposed infection.
6. Instruct the client to complete the entire course of the medication.
7. Instruct the client to keep ear canals dry.

XV. Antihistamines and Decongestants (Box 57-8)

A. Description
1. These medications produce vasoconstriction.
2. These medications stimulate the receptors of the respiratory mucosa.
3. These medications reduce respiratory tissue hyperemia and edema to open obstructed eustachian tubes.
4. These medications are used for acute otitis media.

B. Side and adverse effects
1. Drowsiness
2. Blurred vision
3. Dry mucous membranes

C. Interventions
1. Inform the client that drowsiness, blurred vision, and a dry mouth may occur.
2. Instruct the client to increase fluid intake unless contraindicated and to suck on hard candy to alleviate the dry mouth.
3. Instruct the client to avoid hazardous activities if drowsiness occurs.
4. Instruct the client with hypertension to consult the PHCP prior to the use of these medications.

XVI. Ceruminolytic Medication

A. Carbamide peroxide

B. Description
1. Emulsifies and loosens cerumen deposits
2. Used to loosen and remove impacted wax from the ear canal

C. Side and adverse effects
1. Irritation
2. Redness or swelling of the ear canal

D. Interventions
1. Instruct the client not to use drops more often than prescribed.
2. Moisten a cotton plug with medication and insert the
cotton plug after instilling the ear drops.
3. Keep the container tightly closed and away from moisture.
4. Avoid touching the ear with the dropper.
5. Thirty minutes after instillation, gently irrigate the ear as prescribed with warm water, using a soft rubber bulb ear syringe.
6. Irrigation may be done with hydrogen peroxide solution as prescribed to flush cerumen deposits out of the ear canal.
7. For a chronic cerumen impaction, 1 or 2 drops of mineral oil (if prescribed) will soften the wax.
8. Instruct the client to notify the PHCP if redness, pain, or swelling persists.

**Box 57-1**

**Mydriatic, Cycloplegic, and Anticholinergic Medications**
- Atropine
- Cyclopentolate
- Homatropine
- Phenylephrine
- Scopolamine
- Tropicamide

**Box 57-2**

**Anti-infective Eye Medications**

**Antibacterial**
- Chloramphenicol
- Erythromycin
- Bacitracin

**Aminoglycosides**
- Gentamicin sulfate
- Tobramycin

**Antifungal**
- Natamycin

**Antiviral**
- Ganciclovir
- Trifluridine

**Sulfonamide**
- Sulfacetamide

**Box 57-3**

**Antiinflammatory Eye Medications**

**Corticosteroids**
- Dexamethasone
- Difluprednate
- Fluocinolone
- Fluorometholone; sulfacetamide
- Loteprednol etabonate
- Prednisolone, gentamicin
- Rimexolone

**Ophthalmic Immunosuppressant and Antiinflammatory Agent**

- Cyclosporine

**Nonsteroidal Antiinflammatory Agents**

- Bromfenac
- Diclofenac
- Flurbiprofen sodium
- Ketorolac tromethamine
- Nepafenac

**Mast Cell Stabilizers**

- Azelastine hydrochloride
- Cromolyn sodium
- Epinastine
- Ketotifen fumarate
- Nedocromil sodium
- Olopatadine hydrochloride

**Box 57-4**

**Eye Lubricants**

- Carboxymethylcellulose
- Hydroxypropyl methylcellulose
- Petroleum-based ointment
- Polyvinyl alcohol

**Box 57-5**

**Medications to Treat Glaucoma**

1990
Miotics

- Echothiophate
- Carbachol
- Pilocarpine hydrochloride

β-Adrenergic Blocking Eye Medications

- Betaxolol hydrochloride
- Carteolol hydrochloride
- Levobunolol hydrochloride
- Metipranolol
- Timolol maleate

α-Adrenergic Agonists

- Apraclonidine
- Brimonidine

Prostaglandin Analogs

- Latanoprost
- Tafluprost
- Travoprost
- Bimatoprost

Cholinergic Agonists

- Carbachol
- Pilocarpine hydrochloride
- Echothiophate iodide

Carbonic Anhydrase Inhibitors

- Dorzolamide
- Brinzolamide

1991
FIG. 57-2  Irrigation of the external canal. Cerumen and debris can be removed from the ear by irrigation with warm water. The stream of water is aimed above or below the impaction to allow back pressure to push it out rather than further down the canal.

**Box 57-6  Medications That Affect Hearing**

**Antibiotics**

- Amikacin
- Chloramphenicol
- Erythromycin
- Gentamicin
- Neomycin
- Streptomycin sulfate
- Tetracycline
- Tobramycin sulfate
- Vancomycin

1992
Diuretics

- Ethacrynic acid
- Furosemide

Others

- Cisplatin
- Bleomycin
- Chloroquine
- Nitrogen mustard
- Quinine
- Quinidine
- Sildenafil
- Aspirin
- Ibuprofen
- Naproxen

Box 57-7

Anti-infective Ear Medications

- Acetic acid; aluminum acetate
- Amoxicillin
- Ampicillin
- Cefaclor
- Chloramphenicol
- Ciprofloxacin
- Clarithromycin
- Clindamycin hydrochloride
- Erythromycin
- Gentamicin sulfate otic solution
- Ofloxacin
- Penicillin V potassium
- Trimethoprim; sulfamethoxazole

Box 57-8

Antihistamines and Decongestants

1993
Practice Questions

695. Betaxolol hydrochloride eye drops have been prescribed for a client with glaucoma. Which nursing action is **most appropriate** related to monitoring for side and adverse effects of this medication?

1. Assessing for edema
2. Monitoring temperature
3. Monitoring blood pressure
4. Assessing blood glucose level

696. The nurse is preparing to administer eye drops. Which interventions should the nurse take to administer the drops? **Select all that apply.**

- [ ] 1. Wash hands.
- [ ] 2. Put gloves on.
- [ ] 3. Place the drop in the conjunctival sac.
- [ ] 4. Pull the lower lid down against the cheekbone.
- [ ] 5. Instruct the client to squeeze the eyes shut after instilling the eye drop.
- [ ] 6. Instruct the client to tilt the head forward, open the eyes, and look down.

697. The nurse prepares a client for ear irrigation as prescribed by the primary health care provider. Which action should the nurse take when performing the procedure?

1. Warm the irrigating solution to 98.6° F (37.0° C).
2. Position the client with the affected side up following the irrigation.
3. Direct a slow, steady stream of irrigation solution toward the eardrum.
4. Assist the client to turn her or his head so that the ear to be irrigated is facing upward.

698. The nurse is providing instructions to a client who will be self-administering eye drops. To minimize systemic absorption of the eye drops, the nurse should instruct the client to take which action?

1. Eat before instilling the drops.
2. Swallow several times after instilling the drops.
3. Blink vigorously to encourage tearing after instilling the drops.
4. Occlude the nasolacrimal duct with a finger after instilling the drops.

699. A client is prescribed an eye drop and an eye ointment for the right eye. How should the nurse best administer the medications?
1. Administer the eye drop first, followed by the eye ointment.
2. Administer the eye ointment first, followed by the eye drop.
3. Administer the eye drop, wait 15 minutes, and administer the eye ointment.
4. Administer the eye ointment, wait 15 minutes, and administer the eye drop.

700. Which medication, if prescribed for the client with glaucoma, should the nurse question?
1. Betaxolol
2. Pilocarpine
3. Erythromycin
4. Atropine sulfate

701. A miotic medication has been prescribed for the client with glaucoma, and the client asks the nurse about the purpose of the medication. Which response should the nurse provide to the client?
1. “The medication will help dilate the eye to prevent pressure from occurring.”
2. “The medication will relax the muscles of the eyes and prevent blurred vision.”
3. “The medication causes the pupil to constrict and will lower the pressure in the eye.”
4. “The medication will help block the responses that are sent to the muscles in the eye.”

702. A client was just admitted to the hospital to rule out a gastrointestinal (GI) bleed. The client has brought several bottles of medications prescribed by different specialists. During the admission assessment, the client states, “Lately, I have been hearing some roaring sounds in my ears, especially when I am alone.” Which medication would the nurse identify as the cause of the client’s complaint?
1. Doxycycline
2. Atropine sulfate
3. Acetylsalicylic acid
4. Diltiazem hydrochloride

703. In preparation for cataract surgery, the nurse is to administer cyclopentolate eye drops at 9:00 a.m. for surgery that is scheduled for 9:15 a.m. What initial action should the nurse take in relation to the characteristics of the medication action?
1. Provide lubrication to the operative eye prior to giving the eye drops.
2. Call the surgeon, as this medication will further constrict the operative pupil.
3. Consult the surgeon, as there is not sufficient time for the dilative effects to occur.
4. Give the medication as prescribed; the surgeon needs optimal constriction of the pupil.

Answers

695. Answer: 3

*Rationale:* Hypotension, dizziness, nausea, diaphoresis, headache, fatigue, constipation, and diarrhea are side and adverse effects of the medication. Nursing interventions include monitoring the blood pressure for hypotension and assessing the pulse for strength, weakness, irregular rate, and bradycardia. Options 1, 2, and 4 are not specifically associated with this medication.

*Test-Taking Strategy:* Note the strategic words, most appropriate. Use the ABCs—airway, breathing, and circulation—to direct you to the correct option.

*Level of Cognitive Ability:* Analyzing
*Client Needs:* Physiological Integrity
*Integrated Process:* Nursing Process—Implementation
*Content Area:* Pharmacology: Eye and Ear: Glaucoma Medications
*Health Problem:* Adult Health: Eye: Glaucoma
*Priority Concepts:* Safety; Sensory Perception

696. Answer: 1, 2, 3, 4

*Rationale:* To administer eye medications, the nurse should wash hands and put gloves on. The client is instructed to tilt the head backward, open the eyes, and look up. The nurse pulls the lower lid down against the cheekbone and holds the bottle like a pencil with the tip downward. Holding the bottle, the nurse gently rests the wrist of the hand on the client’s cheek and squeezes the bottle gently to allow the drop to fall into the conjunctival sac. The client is instructed to close the eyes gently and not to squeeze the eyes shut to prevent the loss of medication.

*Test-Taking Strategy:* Focus on the subject, the procedure for administering eye drops. Use guidelines related to standard precautions and visualize this procedure. This will assist in determining the correct interventions.

*Level of Cognitive Ability:* Applying
*Client Needs:* Physiological Integrity
*Integrated Process:* Nursing Process—Implementation
*Content Area:* Skills: Medication Administration
*Health Problem:* N/A
*Priority Concepts:* Clinical Judgment; Safety

697. Answer: 1

*Rationale:* Before ear irrigation, the nurse should inspect the tympanic membrane to ensure that it is intact. The irrigating solution should be warmed to 98.6° F (37.0°
C), because a solution temperature that is not close to the client’s body temperature will cause ear injury, nausea, and vertigo. The nurse should check the temperature of the solution on the inner forearm. The affected side should be down following the irrigation to assist in drainage of the fluid. When irrigating, a direct and slow steady stream of irrigation solution is directed toward the wall of the canal, not toward the eardrum. The client is positioned sitting, facing forward with the head in a natural position; if the ear is faced upward, the nurse would not be able to visualize the canal.

**Test-Taking Strategy:** Focus on the subject, the procedure for performing ear irrigation. Think about the purpose of this procedure and keep safety in mind. Visualizing each step and the information in the options will assist in eliminating the incorrect ones.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Foundations of Care: Safety  
**Health Problem:** N/A  
**Priority Concepts:** Safety; Sensory Perception  

698. **Answer:** 4

**Rationale:** Applying pressure on the nasolacrimal duct prevents systemic absorption of the medication. Options 1, 2, and 3 will not prevent systemic absorption.

**Test-Taking Strategy:** Focus on the subject, systemic effects. Eating and swallowing are comparable or alike and are not related to the systemic absorption of eye drops. Blinking vigorously to produce tearing may result in the loss of the administered medication.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Foundations of Care: Client Teaching  
**Health Problem:** N/A  
**Priority Concepts:** Client Education; Safety  
**Reference:** Lilley et al. (2017), p. 130.

699. **Answer:** 1

**Rationale:** When an eye drop and an eye ointment are scheduled to be administered at the same time, the eye drop is administered first. The instillation of two medications is separated by 3 to 5 minutes.

**Test-Taking Strategy:** Note the strategic word, best. Focus on the subject, the guidelines for administering eye medications. Eliminate options 3 and 4 first because of the words 15 minutes. Next, thinking about the consistency and absorption of a drop versus ointment will direct you to the correct option.

**Level of Cognitive Ability:** Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Skills: Medication Administration
Health Problem: N/A
Priority Concepts: Clinical Judgment; Safety

700. Answer: 4

Rationale: Options 1 and 2 are miotic agents used to treat glaucoma. Option 3 is an anti-infective medication used to treat bacterial conjunctivitis. Atropine sulfate is a mydriatic and cycloplegic (also anticholinergic) medication, and its use is contraindicated in clients with glaucoma. Mydriatic medications dilate the pupil and can cause an increase in intraocular pressure in the eye.

Test-Taking Strategy: Focus on the subject, the medication that the nurse should question. Recalling the classifications of the medications identified in the options will assist in answering the question. Remember that mydriatics dilate the pupil and that these medications are contraindicated in glaucoma.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Analysis
Content Area: Pharmacology: Eye and Ear: Glaucoma Medications
Health Problem: Adult Health: Eye: Glaucoma
Priority Concepts: Collaboration; Safety
Reference: Burchum, Rosenthal (2016), pp. 120, 1272-1273

701. Answer: 3

Rationale: Miotics cause pupillary constriction and are used to treat glaucoma. They lower the intraocular pressure, thereby increasing blood flow to the retina and decreasing retinal damage and loss of vision. Miotics cause a contraction of the ciliary muscle and a widening of the trabecular meshwork. Options 1, 2, and 4 are incorrect.

Test-Taking Strategy: Note that the client has glaucoma. Recall that prevention of increased intraocular pressure is the goal in the client with glaucoma. Options 1, 2, and 4 are comparable or alike and describe actions related to mydriatic medications, which primarily dilate the pupils and relax the ciliary muscles.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Pharmacology: Eye and Ear: Glaucoma Medications
Health Problem: Adult Health: Eye: Glaucoma
Priority Concepts: Client Education; Safety

702. Answer: 3
Rationale: Aspirin (acetylsalicylic acid) is contraindicated for GI bleeding and is potentially ototoxic. The client should be advised to notify the prescribing primary health care provider so the medication can be discontinued and/or a substitute that is less toxic to the ear can be taken instead. Options 1, 2, and 4 do not have effects that are potentially associated with hearing difficulties.

Test-Taking Strategy: Focus on the subject, the medication that may be causing the client’s complaint. Review the classifications and/or therapeutic effects as well as the side and adverse effects of each medication in the options. Of the medications identified, only aspirin can cause ototoxicity. In addition, it is contraindicated for GI bleed.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Analysis
Content Area: Pharmacology: Pain: Nonopioid Analgesics
Health Problem: Adult Health: Ear: Vertigo/tinnitus
Priority Concepts: Safety; Sensory Perception

703. Answer: 3

Rationale: Cyclopentolate is a rapidly acting mydriatic and cycloplegic medication. Cyclopentolate is effective in 25 to 75 minutes, and accommodation returns in 6 to 24 hours. Cyclopentolate is used for preoperative mydriasis, not pupil constriction. The nurse should consult with the surgeon about the time of administration of the eye drops, because 15 minutes is not adequate time for dilation to occur.

Test-Taking Strategy: Note the strategic word, initial. Options 2 and 4 are comparable or alike and are eliminated first (miosis refers to a constricted pupil). Note that the question identifies a client being prepared for eye surgery. The pupil would need to be dilated for the surgical procedure.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Pharmacology: Eye and Ear Medications: Mydriatic, Cycloplegic, Anticholinergics
Health Problem: Adult Health: Eye: Cataracts
Priority Concepts: Clinical Judgment; Safety
UNIT XV
Neurological Problems of the Adult Client
Introduction

Pyramid to Success

Pyramid Points related to neurological disorders focus on nursing care and monitoring for increased intracranial pressure, assessing level of consciousness, positioning clients, head injuries, spinal cord injuries, spinal shock, autonomic dysreflexia, interventions during a seizure, stroke, Parkinson’s disease, myasthenia gravis, and the edrophonium test. Focus on the points related to the psychosocial effects as a result of the neurological disorder, such as anxiety, unexpected body image changes, and the appropriate and available support services needed for the client.

Client Needs: Learning Objectives

Safe and Effective Care Environment

- Acting as a client advocate
- Collaborating with the interprofessional health care team
- Ensuring that advance directives are in the client’s medical record
- Ensuring that informed consent for invasive procedures has been obtained
- Establishing priorities
- Initiating referrals to appropriate services
- Maintaining asepsis with procedures and treatments
- Maintaining confidentiality
- Maintaining standard, transmission-based, and other precautions
- Preventing accidents that can occur as a result of neurological deficits
- Upholding client rights

Health Promotion and Maintenance

- Discussing expected and unexpected body image changes resulting from neurological deficits
- Performing neurological assessment using various techniques
- Preventing and detecting health problems associated with neurological deficits
- Providing home care instructions regarding care related to the neurological disorder
- Teaching about the importance of prescribed therapy
**Psychosocial Integrity**

- Addressing grief and loss issues
- Assessing the ability to cope with feelings of isolation and loss of independence
- Considering the cultural, religious, and spiritual influences of the client when planning care
- Identifying sensory and perceptual alterations
- Identifying support systems and encouraging the use of community resources
- Mobilizing coping mechanisms

**Physiological Integrity**

- Administering pharmacological therapy
- Maintaining nutrition
- Monitoring for alterations in body systems
- Monitoring for complications related to procedures
- Monitoring for fluid and electrolyte imbalances
- Promoting normal elimination patterns
- Promoting self-care measures
- Providing assistive devices for mobility
- Providing emergency care
- Providing measures to promote comfort
CHAPTER 58

Neurological Problems

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts

Functional Ability; Intracranial Regulation

I. Anatomy and Physiology of the Brain and Spinal Cord
   A. Cerebrum
      1. The cerebrum consists of the right and left hemispheres.
      2. Each hemisphere receives sensory information from the opposite side of the body and controls the skeletal muscles of the opposite side.
      3. The cerebrum governs sensory and motor activity and thought and learning.
   B. Cerebral cortex (Box 58-1)
      1. The cerebral cortex is the outer gray layer; it is divided into 5 lobes.
      2. It is responsible for the conscious activities of the cerebrum.
   C. Basal ganglia: Cell bodies in white matter that help the cerebral cortex produce smooth voluntary movements
   D. Diencephalon
      1. Thalamus
         a. Relays sensory impulses to the cortex
         b. Provides a pain gate
         c. Part of the reticular activating system
      2. Hypothalamus
         a. Regulates autonomic responses of the sympathetic and parasympathetic nervous systems
         b. Regulates the stress response, sleep, appetite, body temperature, fluid balance, and emotions
         c. Responsible for the production of hormones secreted by the pituitary gland and the hypothalamus
   E. Brainstem

2003
1. Midbrain
   a. Responsible for motor coordination
   b. Contains the visual reflex and auditory relay centers

2. Pons: Contains the respiratory centers and regulates breathing

3. Medulla oblongata
   a. Contains all afferent and efferent tracts and cardiac, respiratory, vomiting, and vasomotor centers
   b. Controls heart rate, respiration, blood vessel diameter, sneezing, swallowing, vomiting, and coughing

F. Cerebellum: Coordinates muscle movement, posture, equilibrium, and muscle tone

G. Spinal cord
   1. Provides neuron and synapse networks to produce involuntary responses to sensory stimulation
   2. Controls body movement and regulates visceral function
   3. Carries sensory information to and motor information from the brain
   4. Extends from the first cervical to the second lumbar vertebra
   5. Protected by the meninges, cerebrospinal fluid (CSF), and adipose tissue
   6. Horns
      a. Inner column of gray matter; contains 2 anterior and 2 posterior horns
      b. Posterior horns connect with afferent (sensory) nerve fibers.
      c. Anterior horns contain efferent (motor) nerve fibers.
   7. Nerve tracts
      a. White matter contains the nerve tracts.
      b. Ascending tracts (sensory pathway)
      c. Descending tracts (motor pathway)

H. Meninges
   1. The dura mater is a tough and fibrous membrane.
   2. The arachnoid membrane is a delicate membrane and contains CSF.
   3. The pia mater is a vascular membrane.
   4. The subarachnoid space is formed by the arachnoid membrane and the pia mater.

I. CSF

2004
1. Secreted in the ventricles; circulates in the subarachnoid space and through the ventricles to the subarachnoid space of the meninges, where it is reabsorbed
2. Acts as a protective cushion; aids in the exchange of nutrients and wastes
3. Normal pressure is 50 to 175 mm H₂O.
4. Normal volume is 125 to 150 mL.

J. Ventricles
1. Four ventricles
2. The ventricles communicate between the subarachnoid spaces and produce and circulate CSF.

K. Blood supply
1. Right and left internal carotid arteries
2. Right and left vertebral arteries
3. These arteries supply the brain via an anastomosis at the base of the brain called the circle of Willis.

L. Neurotransmitters
1. Acetylcholine
2. Norepinephrine
3. Dopamine
4. Serotonin
5. Amino acids
6. Polypeptides

M. Neurons
1. The neuron consists of the cell body, axon, and dendrites.
2. The cell body contains the nucleus.
3. Neurons carrying impulses from the peripheral nervous system to the central nervous system (CNS) are called sensory neurons.
4. Neurons carrying impulses away from the CNS are called motor neurons.
5. Synapse is the chemical transmission of impulses from one neuron to another.

N. Axons and dendrites
1. The axon conducts impulses from the cell body.
2. The dendrites receive stimuli from the body and transmit them to the axon.
3. The neurons are protected and insulated by Schwann cells.
4. The Schwann cell sheath is called the neurolemma.
5. Neurons do not reproduce after the neonatal period.
6. If an axon or dendrite is damaged, it will die and be replaced slowly only if the neurolemma is intact and the cell body has not died.

O. Spinal nerves
1. There are 31 pairs of spinal nerves.
2. Mixed nerve fibers are formed by the joining of the anterior motor and posterior sensory roots.
3. Posterior roots contain afferent (sensory) nerve fibers.
4. Anterior roots contain efferent (motor) nerve fibers.

P. Autonomic nervous system
1. Sympathetic (adrenergic) fibers dilate pupils, increase heart rate and rhythm, contract blood vessels, and relax smooth muscles of the bronchi.
2. Parasympathetic (cholinergic) fibers produce the opposite effect.

II. Diagnostic Tests
A. Skull and spinal radiography
1. Description
   a. Radiographs of the skull reveal the size and shape of the skull bones, suture separation in infants, fractures or bony defects, erosion, and calcification.
   b. Spinal radiographs identify fractures, dislocation, compression, curvature, erosion, narrowed spinal cord, and degenerative processes.

2. Preprocedure interventions
   a. Provide nursing support for the confused, combative, or ventilator-dependent client.
   b. Maintain immobilization of the neck if a spinal fracture is suspected.
   c. Remove metal items from the client.
   d. If the client has thick and heavy hair, this should be documented because it could affect interpretation of the x-ray film.

3. Postprocedure intervention: Maintain immobilization until results are known.

Always check with the client about the possibility of pregnancy before any radiographic procedures.

B. Computed tomography (CT)
1. Description
   a. A type of brain scanning that may or may not require injection of a dye.
   b. It is used to detect intracranial bleeding, space-occupying lesions, cerebral edema, infarctions, hydrocephalus,
cerebral atrophy, and shifts of brain structures.

An informed consent is needed for any invasive procedure, including those that use a contrast medium (dye).

2. Preprocedure interventions

a. Assess for allergies to iodine, contrast dyes, or shellfish if a dye is used.
b. Assess renal function and verify contrast dose with the pharmacy.
c. Instruct the client of the need to lie still and flat during the test.
d. Instruct the client to hold her or his breath when requested.
e. Initiate an intravenous line with the appropriate gauge size if prescribed.
f. Remove objects from the head, such as wigs, barrettes, earrings, and hairpins.
g. Assess for claustrophobia.
h. Inform the client of possible mechanical noises as the scanning occurs.
i. Inform the client that there may be a hot, flushed sensation and a metallic taste in the mouth when the dye is injected.
j. Note that some clients may be given the dye even if they report an allergy; they may be treated with an antihistamine and corticosteroids before the injection to reduce the severity of a reaction.

Assess the need to withhold metformin if iodinated contrast dye is used for a diagnostic procedure because of the risk for metformin-induced lactic acidosis.

3. Postprocedure interventions

a. Provide replacement fluids, because diuresis from the dye is expected.
b. Monitor for an allergic reaction to the dye.
c. Assess the dye injection site for bleeding or hematoma, and monitor
the extremity for color, warmth, and
the presence of distal pulses.

C. Magnetic resonance imaging (MRI)

1. Description

a. A noninvasive procedure that identifies
tissues, tumors, and vascular
abnormalities.

b. It is similar to CT scanning but provides
more detailed pictures.

2. Preprocedure interventions

a. Remove all metal objects from the
client.

b. Determine whether the client has a
pacemaker, implanted defibrillator, or
other metal implants such as a hip
prosthesis or vascular clips, because
these clients cannot have this test
performed.

c. Insert an intermittent infusion device
(saline lock) to all intravenous accesses
prior to the procedure (intravenous
fluid pumps are not allowed in the
MRI room).

d. Provide precautions for the client who
is attached to a pulse oximeter, because
it can cause a burn during testing if
coiled around the body or a body part.

e. Provide an assessment of the client with
claustrophobia (may not be necessary
if an open MRI machine is used).

f. Administer medication as prescribed for
the client with claustrophobia.

g. Determine whether a contrast agent is
to be used and follow the prescription
related to the administration of food,
fluids, and medications. Verify
allergies and renal function prior to
administration.

h. Instruct the client that she or he will
need to remain still during the
procedure.

An MRI is contraindicated in a pregnant
woman, because the increase in amniotic fluid
temperature that occurs during the procedure may
be harmful to the fetus.
3. Postprocedure interventions
   a. The client may resume normal activities.
   b. Increase fluid intake and expect diuresis if a contrast agent is used.

D. Lumbar puncture
   1. Description
      a. Insertion of a spinal needle through the L3–L4 interspace into the lumbar subarachnoid space to obtain CSF; measure CSF fluid or pressure; or instill air, dye, or medications
      b. The test is contraindicated in clients with increased intracranial pressure (ICP), because the procedure will cause a rapid decrease in pressure in the CSF around the spinal cord, leading to brain herniation.
   2. Preprocedure interventions: Have the client empty the bladder.
   3. Interventions during the procedure
      a. Position the client in a lateral recumbent position and have the client draw the knees up to the abdomen and the chin onto the chest; the prone position may be required for radiologically guided punctures.
      b. Assist with the collection of specimens (label the specimens in sequence).
      c. Maintain strict asepsis.
   4. Postprocedure interventions
      a. Monitor vital signs and neurological signs to check for the presence of leakage of CSF and also monitor for headache.
      b. Position the client flat as prescribed.
      c. Encourage fluids to replace CSF obtained from the specimen collection or from leakage.
      d. Monitor intake and output.

E. Cerebral angiography
   1. Description: Injection of a contrast material usually through the femoral artery (or another artery) into the carotid arteries to visualize the cerebral arteries and assess for lesions
2. Preprocedure interventions
   a. Assess the client for allergies to iodine and shellfish. Assess renal function.
   b. Assess for a medication history of anticoagulation therapy; withhold the anticoagulant medication prior to the procedure as prescribed.
   c. Encourage hydration for 2 days before the test.
   d. Maintain the client on NPO (nothing by mouth) status 4 to 6 hours before the test as prescribed.
   e. Perform a neurological assessment, which will serve as a baseline for postprocedure assessments.
   f. Mark the peripheral pulses.
   g. Remove metal items from the hair.
   h. Administer premedication as prescribed.

3. Postprocedure interventions
   a. Monitor neurological status, vital signs, and neurovascular status of the affected extremity frequently until stable.
   b. Monitor for swelling in the neck and for difficulty swallowing; notify a primary health care provider (PHCP) if these symptoms occur.
   c. Maintain bed rest for 12 hours as prescribed.
   d. Elevate the head of the bed 15 to 30 degrees only if prescribed.
   e. Keep the bed flat, as prescribed, if the femoral artery is used.
   f. Assess peripheral pulses.
   g. Apply sandbags or another device to immobilize the limb and a pressure dressing to the injection site to decrease bleeding as prescribed.
   h. Place ice on the puncture site as prescribed.
   i. Encourage fluid intake.
F. Electroencephalography

1. Description: Graphic recording of the electrical activity of the superficial layers of the cerebral cortex

2. Preprocedure interventions
   a. Wash the client’s hair.
   b. Inform the client that electrodes are attached to the head and that electricity does not enter the head.
   c. Withhold stimulants such as coffee, tea, and caffeine beverages; antidepressants; tranquilizers; and possibly antiseizure medications for 24 to 48 hours before the test as prescribed.
   d. Allow the client to have breakfast if prescribed.
   e. Premedicate for sedation as prescribed.

3. Postprocedure interventions
   a. Wash the client’s hair.
   b. Maintain safety precautions, if the client was sedated.

G. Caloric testing (oculovestibular reflex)

1. Description: Caloric testing provides information about the function of the vestibular portion of cranial nerve VIII and aids in the diagnosis of cerebellar and brainstem lesions.

2. Procedure
   a. Patency of the external auditory canal is confirmed.
   b. The client is positioned supine with the head of the bed elevated 30 degrees.
   c. Water that is warmer or cooler than body temperature is infused into the ear.
   d. A normal response is the onset of vertigo and nystagmus (involuntary eye movements) within 20 to 30 seconds.
   e. Absent or disconjugate eye movements indicate brainstem damage.

III. Neurological Assessment (see Chapter 12 for additional information on neurological assessment)

A. Assessment of risk factors

1. Trauma
2. Hemorrhage
3. Tumors
4. Infection
5. Toxicity
6. Metabolic disorders
7. Hypoxic conditions
8. Hypertension
9. Cigarette smoking
10. Stress
11. Aging process
12. Chemicals, either ingestion or environmental exposure

B. Assessment of cranial nerves (see Chapter 12)
C. Assessment of level of consciousness (LOC) (see Chapter 12)

Level of consciousness is the most sensitive indicator of neurological status.

D. Assessment of vital signs: Monitor for blood pressure or pulse changes, which may indicate increased ICP.

E. Assessment of respirations (Box 58-2)

F. Assessment of temperature
   1. An elevated temperature increases the metabolic rate of the brain.
   2. An elevation in temperature may indicate a dysfunction of the hypothalamus or brainstem.
   3. A slow rise in temperature may indicate infection.

G. Assessment of pupils (Fig. 58-1)
   1. Unilateral pupil dilation indicates compression of cranial nerve III.
   2. Midposition fixed pupils indicate midbrain injury.
   3. Pinpoint fixed pupils indicate pontine damage.

H. Assessment for posturing (see Chapter 38, Fig. 38-3)
   1. Posturing indicates a deterioration of the condition.
   2. Flexor (decorticate posturing)
      a. Client flexes 1 or both arms on the chest and may extend the legs stiffly.
      b. Flexor posturing indicates a nonfunctioning cortex.
   3. Extensor (decerebrate posturing)
      a. Client stiffly extends 1 or both arms and possibly the legs.
      b. Extensor posturing indicates a brainstem lesion.
4. **Flaccid posturing**: Client displays no motor response in any extremity.

I. Assessment of reflexes (Box 58-3)

J. Assessment of meningeal irritation (Box 58-4)

K. Assessment of the autonomic system
   1. Sympathetic functions, adrenergic responses
      a. Increased pulse and blood pressure
      b. Dilated pupils
      c. Decreased peristalsis
      d. Increased perspiration
   2. Parasympathetic function, cholinergic responses
      a. Decreased pulse and blood pressure
      b. Constricted pupils
      c. Increased salivation
      d. Increased peristalsis
      e. Dilated blood vessels
      f. Bladder contraction

L. Assessment of sensory function: Touch, pressure, pain

M. Glasgow Coma Scale (Box 58-5)
   1. The scale is a method of assessing a client’s neurological condition.
   2. The scoring system is based on a scale of 3 to 15 points.
   3. A score lower than 8 indicates that coma is present.

IV. The **Unconscious Client**
   A. Description
      1. The unconscious client is in a state of depressed cerebral functioning with unresponsiveness to stimulation of sensory and motor function.
      2. Some causes include head trauma, cerebral toxins, shock, hemorrhage, tumor, and infection.

   B. Assessment
      1. Unarousable
      2. Primitive or no response to painful stimuli
      3. Altered respirations
      4. Decreased cranial nerve and reflex activity

   C. Interventions (Box 58-6)

V. **Increased Intracranial Pressure (ICP)**
   A. Description
      1. Increased ICP may be caused by trauma, hemorrhage, growths or tumors, hydrocephalus, edema, or inflammation.
      2. Increased ICP can impede circulation to the brain,
impede the absorption of CSF, affect the functioning of nerve cells, and lead to brainstem compression and death.

B. Assessment

1. Altered level of consciousness, which is the most sensitive and earliest indication of increasing ICP
2. Headache
3. Abnormal respirations (see Box 58-2)
4. Rise in blood pressure with widening pulse pressure
5. Slowing of pulse
6. Elevated temperature
7. Vomiting
8. Pupil changes
9. Late signs of increased ICP include increased systolic blood pressure, widened pulse pressure, and slowed heart rate.
10. Other late signs include changes in motor function from weakness to hemiplegia, a positive Babinski’s reflex, decorticate or decerebrate posturing, and seizures.

C. Interventions

1. Monitor respiratory status and prevent hypoxia.
2. Avoid the administration of morphine sulfate to prevent the occurrence of hypoxia.
3. Maintain mechanical ventilation as prescribed; maintaining the PaCO$_2$ at 30 to 35 mm Hg (30 to 35 mm Hg) will result in vasoconstriction of the cerebral blood vessels, decreased blood flow, and therefore decreased ICP.
4. Maintain body temperature.
5. Prevent shivering, which can increase ICP.
6. Decrease environmental stimuli.
7. Monitor electrolyte levels and acid–base balance.
8. Monitor intake and output.
9. Limit fluid intake to 1200 mL/day.
10. Instruct the client to avoid straining activities, such as coughing and sneezing.
11. Instruct the client to avoid Valsalva’s maneuver.

For the client with increased ICP, elevate the head of the bed 30 to 40 degrees, avoid the Trendelenburg’s position, and prevent flexion of the neck and hips.

D. Medications (Box 58-7)
E. Surgical intervention: Also see Chapter 38 for additional information on ventriculoperitoneal shunts (Box 58-8)

VI. Hyperthermia
   A. Description
      1. Temperature higher than 105° F (40.6° C), which increases the cerebral metabolism and increases the risk of hypoxia
      2. Causes include infection, heat stroke, exposure to high environmental temperatures, and dysfunction of the thermoregulatory center.
   B. Assessment
      1. Temperature higher than 105° F (40.6° C)
      2. Shivering
      3. Nausea and vomiting
   C. Interventions
      1. Maintain a patent airway.
      2. Initiate seizure precautions.
      3. Monitor intake and output and assess the skin and mucous membranes for signs of dehydration.
      5. Monitor for dysrhythmias.
      6. Assess peripheral pulses for systemic blood flow.
      7. Induce normothermia with fluids, cool baths, fans, or a hypothermia blanket.
   D. Inducement of normothermia
      1. Prevent shivering, which will increase ICP and oxygen consumption.
      2. Administer medications as prescribed to prevent shivering and to lower body temperature.
      4. Monitor for infection and respiratory complications because hyperthermia may mask the signs of infection.
      5. Monitor for cardiac dysrhythmias.
      7. Prevent trauma to the skin and tissues.
      8. Apply lotion to the skin frequently.
      9. Inspect for frostbite if a hypothermia blanket is used.

VII. Traumatic Head Injury
   A. Description
      1. Head injury is trauma to the skull, resulting in mild to extensive damage to the brain.
      2. Immediate complications include cerebral bleeding, hematomas, uncontrolled increased ICP, infections, and seizures.
3. Changes in personality or behavior, cranial nerve deficits, and any other residual deficits depend on the area of the brain damage and the extent of the damage.

B. Types of head injuries (Box 58-9)
   1. Open
      a. Scalp lacerations
      b. Fractures in the skull
      c. Interruption of the dura mater
   2. Closed
      a. Concussions
      b. Contusions
      c. Fractures

C. Hematoma
   1. Description: A collection of blood in the tissues that can occur as a result of a subarachnoid hemorrhage or an intracerebral hemorrhage.
   2. Assessment
      a. Assessment findings depend on the injury.
      b. Clinical manifestations usually result from increased ICP.
      c. Changing neurological signs in the client
      d. Changes in level of consciousness
      e. Airway and breathing pattern changes
      f. Vital signs change, reflecting increased ICP.
      g. Headache, nausea, and vomiting
      h. Visual disturbances, pupillary changes, and papilledema
      i. Nuchal rigidity (not tested until spinal cord injury is ruled out)
      j. CSF drainage from the ears or nose
      k. Weakness and paralysis
      l. Posturing
      m. Decreased sensation or absence of feeling
      n. Reflex activity changes
      o. Seizure activity

CSF can be distinguished from other fluids by the presence of concentric rings (bloody fluid surrounded by yellowish stain; halo sign) when the fluid is placed on a white sterile background, such as a gauze pad. CSF also tests positive for glucose.
when tested using a strip test.

3. Interventions

a. Monitor respiratory status and maintain a patent airway, because increased carbon dioxide (CO₂) levels increase cerebral edema.

b. Monitor neurological status and vital signs, including temperature.

c. Monitor for increased ICP.

d. Maintain head elevation to reduce venous pressure.

e. Prevent neck flexion.

f. Initiate normothermia measures for increased temperature.

g. Assess cranial nerve function, reflexes, and motor and sensory function.

h. Initiate seizure precautions.

i. Monitor for pain and restlessness.

j. Morphine sulfate or opioid medication may be prescribed to decrease agitation and control restlessness caused by pain for the head-injured client on a ventilator; administer with caution because it is a respiratory depressant and may increase ICP.

k. Monitor for drainage from the nose or ears, because this fluid may be CSF.

l. Do not attempt to clean the nose, suction, or allow the client to blow her or his nose if drainage occurs.

m. Do not clean the ear if drainage is noted, but apply a loose, dry sterile dressing.

n. Check drainage for the presence of CSF.

o. Notify the PHCP if drainage from the ears or nose is noted and if the drainage tests positive for CSF.

p. Instruct the client to avoid coughing because this increases ICP.

q. Monitor for signs of infection.
r. Prevent complications of immobility.
s. Inform the client and family about the possible behavior changes that may occur, including those that are expected and those that need to be reported.

D. Craniotomy
1. Description
a. Surgical procedure that involves an incision through the cranium to remove accumulated blood or a tumor
b. Complications of the procedure include increased ICP from cerebral edema, hemorrhage, or obstruction of the normal flow of CSF.
c. Additional complications include hematomas, hypovolemic shock, hydrocephalus, respiratory and neurogenic complications, pulmonary edema, and wound infections.
d. Complications related to fluid and electrolyte imbalances include diabetes insipidus and inappropriate secretion of antidiuretic hormone.
e. Stereotactic radiosurgery (SRS) may be an alternative to traditional surgery and is usually used to treat tumors and arteriovenous malformations.

2. Preoperative interventions
a. Explain the procedure to the client and family.
b. Prepare to shave the client’s head as prescribed (usually done in the operating room) and cover the head with an appropriate covering.
c. Stabilize the client before surgery.

3. Postoperative interventions (Box 58-10)
4. Postoperative positioning (Box 58-11)

VIII. Cerebral Aneurysm
A. Description: Dilation of the walls of a weakened cerebral artery; can lead to rupture
B. Assessment
1. Headache and pain
2. Irritability
3. Visual changes
4. Tinnitus
5. Hemiparesis
6. Nuchal rigidity
7. Seizures

C. Interventions

1. Maintain a patent airway (suction only with an PHCP’s prescription).
2. Administer oxygen as prescribed.
3. Monitor vital signs and for hypertension or dysrhythmias.
4. Avoid taking temperatures via the rectum.
5. Initiate aneurysm precautions (Box 58-12).

IX. Seizures

A. Description

1. Seizures are an abnormal, sudden, excessive discharge of electrical activity within the brain.
2. Epilepsy is a disorder characterized by chronic seizure activity and indicates brain or CNS irritation.
3. Causes include genetic factors, trauma, tumors, circulatory or metabolic disorders, toxicity, and infections.
4. Status epilepticus involves a rapid succession of epileptic spasms without intervals of consciousness; it is a potential complication that can occur with any type of seizure, and brain damage may result.

B. Types of seizures (Box 58-13)

C. Assessment

1. Seizure history
2. Type of seizure
3. Occurrences before, during, and after the seizure
4. Prodromal signs, such as mood changes, irritability, and insomnia
5. Aura: Sensation that warns the client of the impending seizure
6. Loss of motor activity or bowel and bladder function or loss of consciousness during the seizure
7. Occurrences during the postictal state, such as headache, loss of consciousness, sleepiness, and impaired speech or thinking

D. Interventions

*If the client is having a seizure, maintain a patent airway. Do not force the jaws*
1. Note the time and duration of the seizure.
2. Assess behavior at the onset of the seizure: If the client has experienced an aura, if a change in facial expression occurred, or if a sound or cry occurred from the client.
3. If the client is standing or sitting, place the client on the floor and protect the head and body.
4. Support airway, breathing, and circulation.
5. Administer oxygen.
6. Prepare to suction secretions.
7. Turn the client to the side to allow secretions to drain while maintaining the airway.
8. Prevent injury during the seizure.
9. Remain with the client.
10. Do not restrain the client.
11. Loosen restrictive clothing.
12. Note the type, character, and progression of the movements during the seizure.
14. Administer intravenous medications as prescribed to stop the seizure.
15. Document the characteristics of the seizure.
16. Provide privacy.
17. Monitor behavior following the seizure, such as the state of consciousness, motor ability, and speech ability.
18. Instruct the client about the importance of lifelong medication and the need for follow-up determination of medication blood levels.
19. Instruct the client to avoid alcohol, excessive stress, fatigue, and strobe lights.
20. Encourage the client to contact available community resources, such as the Epilepsy Foundation of America.
21. Encourage the client to wear a MedicAlert bracelet.

X. Stroke (Brain Attack)

A. Description

1. A stroke or brain attack manifests as a sudden focal neurological deficit and is caused by cerebrovascular disease.
2. Cerebral anoxia lasting longer than 10 minutes causes cerebral infarction with irreversible change.
3. Cerebral edema and congestion cause further dysfunction.
4. Diagnosis is determined by a CT scan, electroencephalography, cerebral arteriography, and
MRI. In most facilities, the type of stroke needs to be
determined within a certain time frame after arrival in
order for timely treatment to be initiated.
5. Transient ischemic attack may be a warning sign of an
impending stroke.
6. The permanent disability cannot be determined until
the cerebral edema subsides.
7. The order in which function may return is facial,
swallowing, lower limbs, speech, and arms.
8. Carotid endarterectomy is a surgical intervention used
in stroke management; it is targeted at stroke
prevention, especially in clients with symptomatic
carotid stenosis.
9. The National Institutes of Health through the National
Institute of Neurological Disorders and Stroke
(NINDS) developed the *Know Stroke: Know the Signs.
Act in Time* campaign devised to help educate the
public about the symptoms of stroke and the
importance of getting to the hospital quickly

B. Causes *(Box 58-14)*
1. Thrombosis
2. Embolism
3. Thrombotic and embolic strokes are classified as
ischemic strokes.
4. Hemorrhage from rupture of a vessel; classified as a
hemorrhagic stroke
5. Manifestations of different types of stroke are
similar and, therefore it is critical to determine the
type of stroke occurring; the type cannot be
determined solely based on manifestations, and the
correct and appropriate treatment for the stroke type
must be initiated.

C. Risk factors
1. Atherosclerosis
2. Hypertension
3. Anticoagulation therapy
4. Diabetes mellitus
5. Stress
6. Obesity
7. Oral contraceptives

D. Assessment *(Fig. 58-2; Boxes 58-14 and 58-15)*
A critical factor in the early intervention and treatment of stroke is the accurate identification of stroke manifestations and establishing the onset of the manifestations. Stroke screening scales may be used to identify stroke manifestations quickly. Identification of the type of stroke occurring is critical in determining the appropriate treatment, and this is usually done using imaging such as a CT scan.

1. Assessment findings depend on the area of the brain affected; stroke scales such as the NIH Stroke Scale (stroke.nih.gov/resources/scale.htm) may be used by the health care facility for assessment.
2. Lesions in the cerebral hemisphere result in manifestations on the contralateral side, which is the side of the body opposite the stroke.
3. Airway patency is always a priority.
4. Pulse (may be slow and bounding)
5. Respirations (Cheyne-Stokes)
6. Blood pressure (hypertension)
7. Headache, nausea, and vomiting
8. Facial drooping
9. Nuchal rigidity
10. Visual changes
11. Ataxia
12. Dysarthria
13. Dysphagia
14. Speech changes
15. Decreased sensation to pressure, heat, and cold
16. Bowel and bladder dysfunctions
17. Paralysis

E. Aphasia

1. Expressive
   a. Damage occurs in Broca’s area of the frontal brain.
   b. The client understands what is said but is unable to communicate verbally.
2. Receptive
   a. Injury involves Wernicke’s area in the temporoparietal area.
   b. The client is unable to understand the spoken and often the written word.
3. Global or mixed: Language dysfunction occurs in expression and reception.
4. Interventions for aphasia
   a. Provide repetitive directions.
   b. Break tasks down to 1 step at a time.
   c. Repeat names of objects frequently used.
F. Interventions during the acute phase of stroke

1. Maintain a patent airway and administer oxygen as prescribed.
2. Monitor vital signs.
3. Usually a blood pressure of 150/100 mm Hg is maintained to ensure cerebral perfusion.
4. Suction secretions to prevent aspiration as prescribed, but never suction nasally or for longer than 10 seconds to prevent increased ICP.
5. Monitor for increased ICP, because the client is most at risk during the first 72 hours following the stroke.
6. Position the client on the side to prevent aspiration, with the head of the bed elevated 15 to 30 degrees as prescribed.
7. Monitor level of consciousness, pupillary response, motor and sensory response, cranial nerve function, and reflexes.
8. Maintain a quiet environment.
9. Insert a urinary catheter as prescribed.
10. Administer intravenous fluids as prescribed.
12. Prepare to administer anticoagulants, antiplatelets, diuretics, antihypertensives, and antiseizure medications as prescribed depending on the type of stroke that has been diagnosed.
13. Establish a form of communication.

G. Interventions in the postacute phase of a stroke

1. Continue with interventions from the acute phase.
2. Position the client 2 hours on the unaffected side and 20 minutes on the affected side; the prone position may also be prescribed.
3. Provide skin, mouth, and eye care.
4. Perform passive range-of-motion exercises to prevent contractures.
5. Place antiembolism stockings on the client; remove daily to check skin.
6. Monitor the gag reflex and ability to swallow.
7. Provide sips of fluids and slowly advance diet to foods that are easy to chew and swallow.
8. Provide soft and semisoft foods and flavored, cool or warm, thickened fluids rather than thin liquids, because the stroke client can tolerate these types of food better; speech therapists may do swallow studies...
to recommend consistency of food and fluids.
9. When the client is eating, position the client sitting in a chair or sitting up in bed, with the head and neck positioned slightly forward and flexed.
10. Place food in the back of the mouth on the unaffected side to prevent trapping of food in the affected cheek.

H. Interventions in the chronic phase of stroke

1. Neglect syndrome
   a. The client is unaware of the existence of her or his paralyzed side (unilateral neglect), which places the client at risk for injury.
   b. Teach the client to touch and use both sides of the body.

2. Hemianopsia
   a. The client has blindness in half of the visual field.
   b. Homonymous hemianopsia is blindness in the same visual field of both eyes.
   c. Encourage the client to turn the head to scan the complete range of vision; otherwise, she or he does not see half of the visual field.

3. Approach the client from the unaffected side.
4. Place the client’s personal objects within the visual field.
5. Provide eye care for visual deficits.
6. Place a patch over the affected eye if the client has diplopia.
7. Increase mobility as tolerated.
8. Encourage fluid intake and a high-fiber diet.
9. Administer stool softeners as prescribed.
10. Encourage the client to express her or his feelings.
11. Encourage independence in activities of daily living.
12. Assess the need for assistive devices such as a cane, walker, splint, or braces.
13. Teach transfer technique from bed to chair and from chair to bed.
14. Provide gait training.
15. Initiate physical and occupational therapy for assessment and the need for adaptive equipment or other supports for self-care and mobility.
16. Refer client to a speech and language pathologist as prescribed.
17. Encourage the client and family to contact available community resources.

XI. Multiple Sclerosis
   A. Description
      1. A chronic, progressive, noncontagious, degenerative disease of the CNS characterized by demyelination of the neurons.
      2. It usually occurs between the ages of 20 and 40 years and consists of periods of remissions and exacerbations.
      3. The causes are unknown, but the disease is thought to be the result of an autoimmune response or viral infection.
      4. Precipitating factors include pregnancy, fatigue, stress, infection, and trauma.
      5. Electroencephalographic findings are abnormal.
      6. Assessment of a lumbar puncture indicates an increased gamma globulin level, but the serum globulin level is normal.
   B. Assessment
      1. Fatigue and weakness
      2. Ataxia and vertigo
      3. Tremors and spasticity of the lower extremities
      4. Paresthesias
      5. Blurred vision, diplopia, and transient blindness
      6. Nystagmus
      7. Dysphasia
      8. Decreased perception to pain, touch, and temperature
      9. Bladder and bowel disturbances, including urgency, frequency, retention, and incontinence
      10. Abnormal reflexes, including hyperreflexia, absent reflexes, and a positive Babinski’s reflex
      11. Emotional changes such as apathy, euphoria, irritability, and depression
      12. Memory changes and confusion
   C. Interventions
      1. Provide energy conservation measures during exacerbation.
      2. Protect the client from injury by providing safety measures.
      3. Place an eye patch on the eye for diplopia.
      4. Monitor for potential complications such as urinary tract infections, calculi, pressure ulcers, respiratory tract infections, and contractures.
      5. Promote regular elimination by bladder and bowel
training.
6. Encourage independence.
7. Assist the client to establish a regular exercise and rest program and to balance moderate activity with rest periods.
8. Assess the need for and provide assistive devices.
9. Initiate physical and speech therapy.
10. Instruct the client to avoid fatigue, stress, infection, overheating, and chilling.
11. Instruct the client to increase fluid intake and eat a balanced diet, including low-fat, high-fiber foods and foods high in potassium.
12. Instruct the client in safety measures related to sensory loss, such as regulating the temperature of bath water and avoiding heating pads.
13. Instruct the client in safety measures related to motor loss, such as avoiding the use of scatter rugs and using assistive devices.
14. Instruct the client in the self-administration of prescribed medications.
15. Provide information about the National Multiple Sclerosis Society.

XII. Myasthenia Gravis
A. Description
1. A neuromuscular disease characterized by considerable weakness and abnormal fatigue of the voluntary muscles
2. A defect in the transmission of nerve impulses at the myoneural junction occurs.
3. Causes include insufficient secretion of acetylcholine, excessive secretion of cholinesterase, and unresponsiveness of the muscle fibers to acetylcholine.

B. Assessment
1. Weakness and fatigue
2. Difficulty chewing and swallowing
3. Dysphagia
4. Ptosis
5. Diplopia
6. Weak, hoarse voice
7. Difficulty breathing
8. Diminished breath sounds
9. Respiratory paralysis and failure

C. Interventions
1. Monitor respiratory status and ability to cough and
deep-breathe adequately.
3. Maintain suctioning and emergency equipment at the bedside.
4. Monitor vital signs.
5. Monitor speech and swallowing abilities to prevent aspiration.
6. Encourage the client to sit up when eating.
7. Assess muscle status.
8. Instruct the client to conserve strength.
9. Plan short activities that coincide with times of maximal muscle strength.
10. Monitor for myasthenic and cholinergic crises.
11. Administer anticholinesterase medications as prescribed.
12. Instruct the client to avoid stress, infection, fatigue, and over-the-counter medications.
13. Instruct the client to wear a MedicAlert bracelet.
14. Inform the client about services from the Myasthenia Gravis Foundation.

D. Anticholinesterase medications: Increase levels of acetylcholine at the myoneural junction (see Chapter 59)

E. Myasthenic crisis

1. Description
   a. An acute exacerbation of the disease
   b. The crisis is caused by a rapid, unrecognized progression of the disease, inadequate amount of medication, infection, fatigue, or stress.

2. Assessment
   a. Increased pulse, respirations, and blood pressure
   b. Dyspnea, anoxia, and cyanosis
   c. Bowel and bladder incontinence
   d. Decreased urine output
   e. Absent cough and swallow reflex

3. Interventions
   a. Assess for signs of myasthenic crisis.
   b. Increase anticholinesterase medication, as prescribed.

F. Cholinergic crisis

1. Description
   a. Results in depolarization of the motor end plates
   b. The crisis is caused by overmedication
with anticholinesterase.

2. Assessment
   a. Abdominal cramps
   b. Nausea, vomiting, and diarrhea
   c. Blurred vision
   d. Pallor
   e. Facial muscle twitching
   f. Hypotension
   g. Pupillary miosis

3. Interventions
   a. Withhold anticholinesterase medication.
   b. Prepare to administer the antidote, atropine sulfate, if prescribed.

G. Edrophonium (Tensilon) test

Have atropine sulfate available when performing the edrophonium test.

1. Description
   a. This test is performed by the neurologist to diagnose myasthenia gravis and to differentiate between myasthenic crisis and cholinergic crisis.
   b. The test places the client at risk for ventricular fibrillation and cardiac arrest; emergency equipment needs to be available.

2. To diagnose myasthenia gravis
   a. Edrophonium injection is administered to the client.
   b. Positive for myasthenia gravis: Client shows improvement in muscle strength after the administration of edrophonium.
   c. Negative for myasthenia gravis: Client shows no improvement in muscle strength, and strength may even deteriorate after injection of edrophonium.

3. To differentiate crisis
   a. Myasthenic crisis: Edrophonium is administered and, if strength improves, the client needs more medication.
   b. Cholinergic crisis: Edrophonium is
administered and, if weakness is more severe, the client is overmedicated; prepare to administer atropine sulfate, the antidote, as prescribed.

XIII. Parkinson’s Disease

A. Description
1. A degenerative disease caused by the depletion of dopamine, which interferes with the inhibition of excitatory impulses, resulting in a dysfunction of the extrapyramidal system.
2. It is a slow, progressive disease that results in a crippling disability.
3. The debilitation can result in falls, self-care deficits, failure of body systems, and depression.
4. Mental deterioration occurs late in the disease.

B. Assessment
1. Bradykinesia, abnormal slowness of movement, and sluggishness of physical and mental responses
2. Akinesia
3. Monotonous speech
4. Handwriting that becomes progressively smaller
5. Tremors in hands and fingers at rest (pill rolling)
6. Tremors increasing when fatigued and decreasing with purposeful activity or sleep
7. Rigidly with jerky movements
8. Restlessness and pacing
9. Blank facial expression; mask-like faces
10. Drooling
11. Difficulty swallowing and speaking
12. Loss of coordination and balance
13. Shuffling steps, stooped position, and propulsive gait

C. Interventions
1. Assess neurological status.
2. Assess ability to swallow and chew.
3. Provide high-calorie, high-protein, high-fiber soft diet with small, frequent feedings.
4. Increase fluid intake to 2000 mL/day.
5. Monitor for constipation.
6. Promote independence along with safety measures.
7. Avoid rushing the client with activities.
8. Assist with ambulation and provide assistive devices.
9. Instruct the client to rock back and forth to initiate movement.
10. Instruct the client to wear low-heeled shoes.
11. Encourage the client to lift the feet when walking and
to avoid prolonged sitting.
12. Provide a firm mattress and position the client prone, without a pillow, to facilitate proper posture.
13. Instruct in proper posture by teaching the client to hold the hands behind the back to keep the spine and neck erect.
14. Promote physical therapy and rehabilitation.
15. Administer antiparkinsonian medications to increase the level of dopamine in the CNS.
16. Instruct the client to avoid foods high in vitamin B<sub>6</sub>, because they block the effects of antiparkinsonian medications.
17. Avoid the use of monoamine oxidase inhibitors, because they will precipitate hypertensive crisis.
18. See Chapter 59 regarding medication to treat Parkinson’s disease.

XIV. Trigeminal Neuralgia
A. Description
1. A sensory disorder of the trigeminal (fifth cranial) nerve
2. It results in severe, recurrent, sharp facial pain along the trigeminal nerve.

B. Assessment
1. The client has severe pain on the lips, gums, or nose, or across the cheeks.
2. Situations that stimulate symptoms include cold, washing the face, chewing, or food or fluids of extreme temperatures.

C. Interventions
1. Instruct the client to avoid hot or cold foods and fluids.
2. Provide small feedings of liquid and soft foods.
3. Instruct the client to chew food on the unaffected side.
4. Administer medications as prescribed (see Chapter 59).

D. Surgical interventions
1. Microvascular decompression: Surgical relocation of the artery that compresses the trigeminal nerve as it enters the pons, which may relieve pain without compromising facial sensation
2. Radiofrequency waveforms: Create lesions that provide relief of pain without compromising touch or motor function
3. Rhizotomy: Resection of the root of the nerve to relieve pain
4. Glycerol injection: Destroys the myelinated fibers of the trigeminal nerve (may take up to 3 weeks for pain relief to occur)

XV. Bell’s Palsy (Facial Paralysis)
   A. Description
   1. Caused by a lower motor neuron lesion of cranial nerve VII that may result from infection, trauma, hemorrhage, meningitis, or tumor.
   2. It results in paralysis of 1 side of the face.
   3. Recovery usually occurs in a few weeks, without residual effects.
   
   B. Assessment
   1. Flaccid facial muscles
   2. Inability to raise the eyebrows, frown, smile, close the eyelids, or puff out the cheeks
   3. Upward movement of the eye when attempting to close the eyelid
   4. Loss of taste

   C. Interventions
   1. Encourage facial exercises to prevent the loss of muscle tone (a face sling may be prescribed to prevent stretching of weak muscles).
   2. Protect the eyes from dryness and prevent injury.
   3. Promote frequent oral care.
   4. Instruct the client to chew on the unaffected side.

XVI. Guillain-Barré Syndrome
   A. Description
   1. An acute infectious neuronitis of the cranial and peripheral nerves.
   2. The immune system overreacts to the infection and destroys the myelin sheath.
   3. The syndrome usually is preceded by a mild upper respiratory infection or gastroenteritis.
   4. The recovery is a slow process and can take years.

   The major concern in Guillain-Barré syndrome is difficulty breathing; monitor respiratory status closely.

   B. Assessment
   1. Paresthesias
   2. Pain and/or hypersensitivity such as with the weight of bed sheets or other items touching the body
   3. Weakness of lower extremities
   4. Gradual progressive weakness of the upper extremities and facial muscles
5. Possible progression to respiratory failure
6. Cardiac dysrhythmias
7. CSF that reveals an elevated protein level
8. Abnormal electroencephalogram

C. Interventions
1. Care is directed toward the treatment of symptoms, including pain management.
2. Monitor respiratory status closely.
3. Provide respiratory treatments.
4. Prepare to initiate respiratory support.
5. Monitor cardiac status.
7. Provide the client and family with support.

XVII. Amyotrophic Lateral Sclerosis
A. Description
1. Also known as Lou Gehrig’s disease
2. It is a progressive degenerative disease involving the motor system.
3. The sensory and autonomic systems are not involved, and mental status changes do not result from the disease.
4. The cause of the disease may be related to an excess of glutamate, a chemical responsible for relaying messages between the motor neurons.
5. As the disease progresses, muscle weakness and atrophy develop until a flaccid tetraplegia develops.
6. Eventually, the respiratory muscles become affected, leading to respiratory compromise, pneumonia, and death.
7. No cure is known, and the treatment is symptomatic.

B. Assessment
1. Respiratory difficulty
2. Fatigue while talking
3. Muscle weakness and atrophy
4. Tongue atrophy
5. Dysphagia
6. Weakness of the hands and arms
7. Fasciculations of the face
8. Nasal quality of speech
9. Dysarthria

C. Interventions
1. Care is directed toward the treatment of symptoms.
2. Monitor respiratory status and institute measures to prevent aspiration.
3. Provide respiratory treatments.
4. Prepare to initiate respiratory support.
5. Assess for complications of immobility.
6. Address advance directives as appropriate.
7. Provide the client and family with psychosocial support.

XVIII. Encephalitis

A. Description
1. An inflammation of the brain parenchyma and often of the meninges.
2. It affects the cerebrum, brainstem, and cerebellum.
3. It most often is caused by a viral agent, although bacteria, fungi, or parasites also may be involved.
4. Viral encephalitis is almost always preceded by a viral infection.

B. Transmission
1. Arboviruses can be transmitted to human beings through the bite of an infected mosquito or tick.
2. Echovirus, coxsackievirus, poliovirus, herpes zoster virus, and viruses that cause mumps and chickenpox are common enteroviruses associated with encephalitis.
3. Herpes simplex type 1 virus can cause viral encephalitis.
4. The organism that causes amebic meningoencephalitis can enter the nasal mucosa of persons swimming in warm fresh water, such as a pond or lake.

C. Assessment
1. Presence of cold sores, lesions, or ulcerations of the oral cavity
2. History of insect bites and swimming in fresh water
3. Exposure to infectious diseases
4. Travel to areas where the disease is prevalent
5. Fever
6. Nausea and vomiting
7. Nuchal rigidity
8. Changes in level of consciousness and mental status
9. Signs of increased ICP
10. Motor dysfunction and focal neurological deficits

D. Interventions
1. Monitor vital and neurological signs.
2. Assess level of consciousness using the Glasgow Coma
Scale.
3. Assess for mental status changes and personality and behavior changes.
4. Assess for signs of increased ICP.
5. Assess for the presence of nuchal rigidity and a positive **Kernig’s sign** or **Brudzinski’s sign**, indicating meningeal irritation (Fig. 58-3).
6. Assist the client to turn, cough, and deep-breathe frequently.
7. Elevate the head of the bed 30 to 45 degrees.
8. Assess for muscle and neurological deficits.
9. Administer acyclovir as prescribed (usually the medication of choice for herpes encephalitis).
10. Initiate rehabilitation as needed for motor dysfunction or neurological deficits.

XIX. West Nile Virus Infection

A. Description
1. A potentially serious illness that affects the CNS
2. The virus is contracted primarily by the bite of an infected mosquito (mosquitoes become carriers when they feed on infected birds).
3. Symptoms typically develop between 3 and 14 days after being bitten by the infected mosquito.
4. Neurological effects can be permanent.

B. Assessment
1. Many individuals will not experience any symptoms.
2. Mild symptoms include fever; headache and body aches; nausea; vomiting; swollen glands; or a rash on the chest, stomach, or back.
3. Severe symptoms include a high fever, headache, neck stiffness, stupor, disorientation, tremors, muscle weakness, vision loss, numbness, paralysis, seizures, or coma.

C. Interventions are supportive; there is no specific treatment for the virus.

D. Prevention
1. Use insect repellents containing DEET (diethyltoluamide) when outdoors and wear long sleeves and pants and light-colored clothing.
2. Stay indoors at dusk and dawn when mosquitoes are most active.
3. Ensure that mosquito breeding sites are eliminated, such as standing water and water in bird baths, and keep wading pools empty and on their sides when not in use.

XX. Meningitis

A. Description
1. An inflammation of the arachnoid and pia mater of the brain and spinal cord
2. It is caused by bacterial and viral organisms, although fungal and protozoan meningitis also occur.
3. Predisposing factors include skull fractures, brain or spinal surgery, sinus or upper respiratory infections, the use of nasal sprays, and a compromised immune system.

4. CSF is analyzed to determine the diagnosis and type of meningitis. In meningitis, CSF is cloudy, with increased protein, increased white blood cells, and decreased glucose counts.

B. Transmission: Transmission occurs in areas of high population density, crowded living areas such as college dormitories, and prisons.

Transmission of meningitis is by direct contact, including droplet spread.

C. Assessment (see Box 58-4)

1. Mild lethargy
2. Photophobia
3. Deterioration in the level of consciousness
4. Signs of meningeal irritation, such as nuchal rigidity and a positive Kernig’s sign and Brudzinski’s sign
5. Red, macular rash with meningococcal meningitis
6. Abdominal and chest pain with viral meningitis

D. Interventions

1. Monitor vital signs and neurological signs.
2. Assess for signs of increased ICP.
3. Initiate seizure precautions.
5. Monitor for signs of meningeal irritation.
7. Assess peripheral vascular status (septic emboli may block circulation).
8. Maintain isolation precautions as necessary with bacterial meningitis.
9. Maintain urine and stool precautions with viral meningitis.
10. Maintain respiratory isolation for the client with pneumococcal meningitis.
11. Elevate the head of the bed 30 degrees, and avoid neck flexion and extreme hip flexion.
12. Prevent stimulation and restrict visitors.
13. Administer analgesics and/or antibiotics as prescribed.

**Box 58-1**

**Cerebral Cortex**

**Frontal Lobe**
- Broca’s area for production of speech
- Morals, emotions, reasoning and judgment, concentration, and abstraction

**Parietal Lobe**
- Interpretation of taste, pain, touch, temperature, and pressure
- Spatial perception

**Temporal Lobe**
- Auditory center
- Wernicke’s area for comprehension of speech

**Occipital Lobe**
- Visual area

**Limbic System**
- Emotional and visceral patterns for survival
- Learning and memory

**Box 58-2**

**Assessment of Respirations**

**Cheyne-Stokes**
- Rhythmic, with periods of apnea
- Can indicate a metabolic dysfunction or dysfunction in the cerebral hemisphere or basal ganglia

**Neurogenic Hyperventilation**
• Regular rapid and deep sustained respirations
  • Indicates a dysfunction in the low midbrain and middle pons

**Apneustic**

• Irregular respirations, with pauses at the end of inspiration and expiration
  • Indicates a dysfunction in the middle or caudal pons

**Ataxic**

• Totally irregular in rhythm and depth
  • Indicates a dysfunction in the medulla

**Cluster**

• Clusters of breaths with irregularly spaced pauses
  • Indicates a dysfunction in the medulla and pons
**FIG. 58-1**  Pupillary check for size and response.

<tr>
<td>Pinpoint pupils (pons damage or drugs)</td>
<td></td>
</tr>
</tbody>
</table>

---

**Box 58-3**

**Assessment of Reflexes**

**Babinski’s Reflex**

- Dorsiflexion of the big toe and fanning of the other toes; elicited by firmly stroking the lateral aspect of the sole of the foot
- Is a pathological or abnormal reflex in anyone older than 2 years and represents the presence of central nervous system (CNS) disease
**Corneal (Blink) Reflex**

- Involuntary closure of the eyelids in response to stimulation of the cornea
- Loss of the blink reflex indicates a dysfunction of cranial nerve V.

**Gag Reflex**

- Contraction of pharyngeal muscle, elicited by touching the back of the throat
- Loss of the gag reflex indicates a dysfunction of cranial nerves IX and X.

---

**Box 58-4**

**Assessment of Meningeal Irritation**

**General Findings**

- Irritability
- Nuchal rigidity
- Severe, unrelenting headaches
- Generalized muscle aches and pains
- Nausea and vomiting
- Fever and chills
- Tachycardia
- Photophobia
- Nystagmus
- Abnormal pupil reaction and eye movement

**Brudzinski’s Sign**

- Involuntary flexion of the hip and knee when the neck is passively flexed; indicates meningeal irritation

**Kernig’s Sign**

- Loss of the ability of a supine client to straighten the leg completely when it is fully flexed at the knee and hip; indicates meningeal irritation

**Motor Response**

- Hemiparesis, hemiplegia, and decreased muscle tone
- Cranial nerve dysfunction, especially cranial nerves III, IV, VI, VII, and VIII
Memory Changes

- Short attention span
- Personality and behavioral changes
- Bewilderment

Box 58-5

Glasgow Coma Scale

Score

- The lowest possible score is 3 points (deep coma or death).
- The highest possible score is 15 points (fully awake).

Motor Response Points

- Obeys a simple response = 6
- Localizes painful stimuli = 5
- Normal flexion (withdrawal) = 4
- Abnormal flexion (decorticate posturing) = 3
- Extensor response (decerebrate posturing) = 2
- No motor response to pain = 1

Verbal Response Points

- Oriented = 5
- Confused conversation = 4
- Inappropriate words = 3
- Responds with in comprehensible sounds = 2
- No verbal response = 1

Eye-Opening Points

- Spontaneous = 4
- In response to sound = 3
- In response to pain = 2
- No response, even to painful stimuli = 1

Data from Ignatavicius D, Workman M: Medical-surgical nursing: patient-centered collaborative care, ed 7, St. Louis, 2013, Saunders.
### Care of the Unconscious Client

- Assess patency of the airway and keep airway and emergency equipment readily available.
- Monitor blood pressure, pulse, and heart sounds.
- Assess respiratory and circulatory status.
- Do not leave the client unattended if unstable.
- Maintain a patent airway and ventilation, because a high carbon dioxide (CO\(_2\)) level increases intracranial pressure.
- Assess lung sounds for the accumulation of secretions; suction as needed.
- Assess neurological status, including level of consciousness, pupillary reactions, and motor and sensory function, using a coma scale.
- Place the client in a semi-Fowler’s position.
- Change position of the client every 2 hours, avoiding injury when turning.
- Avoid Trendelenburg’s position.
- Use side rails unless contraindicated or according to agency protocol.
- Assess for edema.
- Monitor for dehydration.
- Monitor intake and output and daily weight.
- Maintain NPO (nothing by mouth) status until consciousness returns.
- Maintain nutrition as prescribed (intravenous or enteral feedings), and monitor fluid and electrolyte balance (when consciousness returns, check the gag and swallow reflex before resuming a diet).
- Assess bowel sounds.
- Monitor elimination patterns.
- Monitor for constipation, impaction, and paralytic ileus.
- Maintain urinary output to prevent stasis, infection, and calculus formation.
- Monitor the status of skin integrity.
- Initiate measures to prevent skin breakdown.
- Provide frequent mouth care.
- Remove dentures and contact lenses.
- Assess the eyes for the presence of a corneal reflex and irritation, and instill artificial tears or cover the eyes with eye patches.
- Monitor drainage from the ears or nose for the presence of cerebrospinal fluid.
- Assume that the unconscious client can hear.
- Avoid restraints.
- Initiate seizure precautions if necessary.
- Provide range-of-motion exercises to prevent contractures.
- Use a footboard or high-topped sneakers to prevent footdrop.
- Use splints to prevent wrist deformities.
- Initiate physical therapy as appropriate.

**Box 58-7**

**Medications for Increased Intracranial Pressure**

**Antiseizure**

- Seizures increase metabolic requirements and cerebral blood flow and volume, thus increasing intracranial pressure (ICP).
- Medications may be given prophylactically to prevent seizures.

**Antipyretics and Muscle Relaxants**

- Temperature reduction decreases metabolism, cerebral blood flow, and thus ICP.
- Antipyretics prevent temperature elevations.
- Muscle relaxants prevent shivering.

**Blood Pressure Medication**

- Blood pressure medication may be required to maintain cerebral perfusion at a normal level.
- Notify the primary health care provider if the blood pressure range is lower than 100 or higher than 150 mm Hg systolic.

**Corticosteroids**

- Corticosteroids stabilize the cell membrane and reduce leakiness of the blood-brain barrier.
- Corticosteroids decrease cerebral edema.
- A histamine blocker may be administered to counteract the excess gastric secretion that occurs with the corticosteroid.
- Clients must be withdrawn slowly from corticosteroid therapy to reduce the risk of adrenal crisis.

**Intravenous Fluids**

- Fluids are administered intravenously via an infusion pump to control the amount administered.
- Infusions are monitored closely because of the risk of promoting additional cerebral edema and fluid overload.
**Hyperosmotic Agent**

- A hyperosmotic agent increases intravascular pressure by drawing fluid from the interstitial spaces and from the brain cells.
- Monitor renal function.
- Diuresis is expected.

**Box 58-8**

**Surgical Intervention for Chronic Increased Intracranial Pressure: Ventriculoperitoneal Shunt**

**Description**

- A ventriculoperitoneal shunt diverts cerebrospinal fluid from the ventricles into the peritoneum.

**Postprocedure Interventions**

- Position the client supine and turn from the back to the nonoperative side.
- Monitor for signs of increasing intracranial pressure resulting from shunt failure.
- Monitor for signs of infection.

**Box 58-9**

**Types of Head Injuries**

**Concussion**

- Concussion is a jarring of the brain within the skull; there may or may not be a loss of consciousness.

**Contusion**

- Contusion is a bruising type of injury to the brain tissue.
- Contusion may occur along with other neurological injuries, such as with subdural or extradural collections of blood.

**Skull Fractures**

- Linear
- Depressed
Epidural Hematoma

- The most serious type of hematoma, epidural hematoma forms rapidly and results from arterial bleeding.
- The hematoma forms between the dura and skull from a tear in the meningeal artery.
- It is often associated with temporary loss of consciousness, followed by a lucid period that then rapidly progresses to coma.
- Epidural hematoma is a surgical emergency.

Subdural Hematoma

- Subdural hematoma forms slowly and results from a venous bleed.
- It occurs under the dura as a result of tears in the veins crossing the subdural space.

Intracerebral Hemorrhage

- Intracerebral hemorrhage occurs when a blood vessel within the brain ruptures, allowing blood to leak inside the brain.

Subarachnoid Hemorrhage

- A subarachnoid hemorrhage is bleeding into the subarachnoid space. It may occur as a result of head trauma or spontaneously, such as from a ruptured cerebral aneurysm.

Box 58-10
Nursing Care Following Craniotomy

- Monitor vital signs and neurological status every 30 to 60 minutes.
- Monitor for increased intracranial pressure (ICP).
- Monitor for decreased level of consciousness, motor weakness or paralysis, aphasia, visual changes, and personality changes.
- Maintain mechanical ventilation and slight hyperventilation for the first 24 to 48 hours as prescribed to prevent increased ICP.
- Assess the primary health care provider’s (PHCP’s) prescription regarding client positioning.
- Avoid extreme hip or neck flexion, and maintain the head in a midline neutral position.
• Provide a quiet environment.
• Monitor the head dressing frequently for signs of drainage.
• Mark any area of drainage at least once each nursing shift for baseline comparison.
• Monitor the drain, which may be in place for 24 hours; maintain suction on the drain as prescribed.
• Measure drainage from the drain every 8 hours, and record the amount and color.
• Notify the PHCP if drainage is more than the normal amount of 30 to 50 mL per shift.
• Notify the PHCP immediately of excessive amounts of drainage or a saturated head dressing.
• Record strict measurement of hourly intake and output.
• Maintain fluid restriction at 1500 mL/day as prescribed.
• Monitor electrolyte levels.
• Monitor for dysrhythmias, which may occur as a result of fluid or electrolyte imbalance.
• Apply ice packs or cool compresses as prescribed; expect periorbital edema and ecchymosis of 1 or both eyes.
• Provide range-of-motion exercises every 8 hours.
• Place antiembolism stockings on the client as prescribed.
• Administer antiseizure medications, antacids, corticosteroids, and antibiotics as prescribed.
• Administer analgesics such as codeine sulfate or acetaminophen as prescribed for pain.

Box 58-11
Client Positioning Following Craniotomy

• Positions prescribed following a craniotomy vary with the type of surgery and the specific postoperative primary health care provider’s (PHCP’s) prescription.
• Always check the PHCP’s prescription regarding client positioning.
• Incorrect positioning may cause serious and possibly fatal complications.

Removal of a Bone Flap for Decompression

• To facilitate brain expansion, the client should be turned from the back to the nonoperative side, but not to the side on which the operation was performed.

Posterior Fossa Surgery
To protect the operative site from pressure and minimize tension on the suture line, position the client on the side, with a pillow under the head for support, and not on the back.

**Infratentorial Surgery**

- Infratentorial surgery involves surgery below the tentorium of the brain.
- The PHCP may prescribe a flat position without head elevation or may prescribe that the head of the bed be elevated at 30 to 45 degrees.
- Do not elevate the head of the bed in the acute phase of care following surgery without an PHCP’s prescription.

**Supratentorial Surgery**

- Supratentorial surgery involves surgery above the tentorium of the brain.
- The PHCP may prescribe that the head of the bed be elevated at 30 degrees to promote venous outflow through the jugular veins.
- Do not lower the head of the bed in the acute phase of care following surgery without a PHCP’s prescription.

**Box 58-12**

**Aneurysm Precautions**

- Maintain the client on bed rest in a semi-Fowler’s or a side-lying position.
- Maintain a darkened room (subdued lighting and avoid direct, bright, artificial lights) without stimulation (a private room is optimal).
- Provide a quiet environment (avoid activities or startling noises); a telephone in the room is not usually allowed.
- Reading, watching television, and listening to music are permitted, provided that they do not overstimulate the client.
- Limit visitors.
- Maintain fluid restrictions.
- Provide diet as prescribed; avoid stimulants in the diet.
- Prevent any activities that initiate the Valsalva maneuver (straining at stool, coughing); provide stool softeners to prevent straining.
- Administer care gently (such as the bath, back rub, range of motion).
- Limit invasive procedures.
- Maintain normothermia.
- Prevent hypertension.
- Provide sedation.
- Provide pain control.
• Administer prophylactic antiseizure medications.
• Provide deep vein thrombosis (DVT) prophylaxis as prescribed.

**Box 58-13**

**Types of Seizures**

**Generalized Seizures**

**Tonic-Clonic**

• Tonic-clonic seizures may begin with an aura.
• The tonic phase involves the stiffening or rigidity of the muscles of the arms and legs and usually lasts 10 to 20 seconds, followed by loss of consciousness.
• The clonic phase consists of hyperventilation and jerking of the extremities and usually lasts about 30 seconds.
• Full recovery from the seizure may take several hours.

**Absence**

• A brief seizure that lasts seconds, and the individual may or may not lose consciousness.
• No loss or change in muscle tone occurs.
• Seizures may occur several times during a day.
• The victim appears to be daydreaming.
• This type of seizure is more common in children.

**Myoclonic**

• Myoclonic seizures present as a brief generalized jerking or stiffening of extremities.
• The victim may fall from the seizure.

**Atonic or Akinetic (Drop Attacks)**

• An atonic seizure is a sudden momentary loss of muscle tone.
• The victim may fall as a result of the seizure.

**Partial Seizures**

**Simple Partial**

• The simple partial seizure produces sensory symptoms accompanied by motor symptoms that are localized or confined to a specific area.
• The client remains conscious and may report an aura.
## Complex Partial

- The complex partial seizure is a psychomotor seizure.
- The area of the brain most usually involved is the temporal lobe.
- The seizure is characterized by periods of altered behavior of which the client is not aware.
- The client loses consciousness for a few seconds.

## Box 58-14

### Clinical Manifestations of Stroke Based on Type

#### Thrombotic Stroke

- Typically, there is no decreased level of consciousness within the first 24 hours.
- Symptoms get progressively worse as the infarction and edema increase.

#### Embolic Stroke

- Sudden, severe symptoms
- Warning signs are less common.
- Client remains conscious and may have a headache.

#### Hemorrhagic Stroke

- Sudden onset of symptoms
- Symptoms progress over minutes to hours due to ongoing bleeding.
Right-brain damage
(stroke on right side of the brain)

- Impaired judgment
- Impaired time concepts
- Impulsive, safety problems
- Left-sided neglect
- Paralyzed left side: hemiplegia
- Rapid performance, short attention span
- Spatial-perceptual deficits
- Tends to deny or minimize problems

Left-brain damage
(stroke on left side of the brain)

- Aware of deficits: depression, anxiety
- Impaired comprehension related to language, math
- Impaired right/left discrimination
- Impaired speech/language aphasias
- Paralyzed right side: hemiplegia
- Slow performance, cautious

**FIG. 58-2** Manifestations of right brain and left brain stroke.

**Box 58-15**

**Assessment Findings in a Stroke**
Agnosia

▪ The inability to recognize familiar objects or persons

Apraxia

▪ Called *dyspraxia* if the condition is mild
▪ Characterized by loss of ability to execute or carry out skilled movements or gestures, despite having the desire and physical ability to perform them

Hemianopsia

▪ Blindness in half the visual field

Homonymous Hemianopsia

▪ Loss of half of the field of view on the same side in both eyes

Neglect Syndrome (Unilateral Neglect)

▪ Client unaware of the existence of her or his paralyzed side

Proprioception Alterations

▪ Altered position sense that places the client at increased risk of injury
▪ *Pyramid Point*: With visual problems, the client must turn the head to scan the complete range of vision.

FIG. 58-3 Kernig’s sign and Brudzinski’s sign.
Priority Nursing Actions

Autonomic Dysreflexia in a Spinal Cord Injury Client

1. Raise the head of the bed and ask that the primary health care provider (PHCP) be notified.
2. Loosen tight clothing on the client.
3. Check for bladder distention or other noxious stimulus.
4. Administer an antihypertensive medication.
5. Document the occurrence, treatment, and response.

Reference

Practice Questions

704. The nurse is assessing the motor and sensory function of an unconscious client who sustained a head injury. The nurse should use which technique to test the client’s peripheral response to pain?
   1. Sternal rub
   2. Nailbed pressure
   3. Pressure on the orbital rim
   4. Squeezing of the sternocleidomastoid muscle

705. The nurse is caring for the client with increased intracranial pressure as a result of a head injury? The nurse would note which trend in vital signs if the intracranial pressure is rising?
   1. Increasing temperature, increasing pulse, increasing respirations, decreasing blood pressure
   2. Increasing temperature, decreasing pulse, decreasing respirations, increasing blood pressure
   3. Decreasing temperature, decreasing pulse, increasing respirations, decreasing blood pressure
   4. Decreasing temperature, increasing pulse, decreasing respirations, increasing blood pressure

706. A client recovering from a head injury is participating in care. The nurse determines that the client understands measures to prevent elevations in intracranial pressure if the nurse observes the client doing which activity?
   1. Blowing the nose
   2. Isometric exercises
   3. Coughing vigorously
   4. Exhaling during repositioning

707. A client has clear fluid leaking from the nose following a basilar skull fracture. Which finding would alert the nurse that cerebrospinal fluid is
1. Fluid is clear and tests negative for glucose.
2. Fluid is grossly bloody in appearance and has a pH of 6.
3. Fluid clumps together on the dressing and has a pH of 7.
4. Fluid separates into concentric rings and tests positive for glucose.

708. A client with a spinal cord injury is prone to experiencing autonomic dysreflexia. The nurse should include which measures in the plan of care to minimize the risk of occurrence? **Select all that apply.**

- [ ] 1. Keeping the linens wrinkle-free under the client
- [ ] 2. Preventing unnecessary pressure on the lower limbs
- [ ] 3. Limiting bladder catheterization to once every 12 hours
- [ ] 4. Turning and repositioning the client at least every 2 hours
- [ ] 5. Ensuring that the client has a bowel movement at least once a week

709. The nurse is evaluating the neurological signs of a client in spinal shock following spinal cord injury. Which observation indicates that spinal shock persists?

- [ ] 1. Hyperreflexia
- [ ] 2. Positive reflexes
- [ ] 3. Flaccid paralysis
- [ ] 4. Reflex emptying of the bladder

710. The nurse is caring for a client who begins to experience seizure activity while in bed. Which actions should the nurse take? **Select all that apply.**

- [ ] 1. Loosening restrictive clothing.
- [ ] 2. Restraining the client’s limbs.
- [ ] 3. Removing the pillow and raising padded side rails.
- [ ] 4. Positioning the client to the side, if possible, with the head flexed forward.
- [ ] 5. Keeping the curtain around the client and the room door open so when help arrives they can quickly enter to assist.

711. The nurse is assigned to care for a client with complete right-sided hemiparesis from a stroke (brain attack). Which characteristics are associated with this condition? **Select all that apply.**

- [ ] 1. The client is aphasic.
- [ ] 2. The client has weakness on the right side of the body.
- [ ] 3. The client has complete bilateral paralysis of the arms and legs.
- [ ] 4. The client has weakness on the right side of the face and tongue.
5. The client has lost the ability to move the right arm but is able to walk independently.

6. The client has lost the ability to ambulate independently but is able to feed and bathe herself or himself without assistance.

712. The nurse has instructed the family of a client with stroke (brain attack) who has homonymous hemianopsia about measures to help the client overcome the deficit. Which statement suggests that the family understands the measures to use when caring for the client?
   1. “We need to discourage him from wearing eyeglasses.”
   2. “We need to place objects in his impaired field of vision.”
   3. “We need to approach him from the impaired field of vision.”
   4. “We need to remind him to turn his head to scan the lost visual field.”

713. The nurse is assessing the adaptation of a client to changes in functional status after a stroke (brain attack). Which observation indicates to the nurse that the client is adapting most successfully?
   1. Gets angry with family if they interrupt a task
   2. Experiences bouts of depression and irritability
   3. Has difficulty with using modified feeding utensils
   4. Consistently uses adaptive equipment in dressing self

714. The nurse is teaching a client with myasthenia gravis about the prevention of myasthenic and cholinergic crises. Which client activity suggests that teaching is most effective?
   1. Taking medications as scheduled
   2. Eating large, well-balanced meals
   3. Doing muscle-strengthening exercises
   4. Doing all chores early in the day while less fatigued

715. The nurse is instructing a client with Parkinson’s disease about preventing falls. Which client statement reflects a need for further teaching?
   1. “I can sit down to put on my pants and shoes.”
   2. “I try to exercise every day and rest when I’m tired.”
   3. “My son removed all loose rugs from my bedroom.”
   4. “I don’t need to use my walker to get to the bathroom.”

716. The nurse has given suggestions to a client with trigeminal neuralgia about strategies to minimize episodes of pain. The nurse determines that the client needs further teaching if the client makes which statement?
   1. “I will wash my face with cotton pads.”
   2. “I’ll have to start chewing on my unaffected side.”
   3. “I should rinse my mouth if toothbrushing is painful.”
   4. “I’ll try to eat my food either very warm or very cold.”

717. The client is admitted to the hospital with a diagnosis of Guillain-Barré syndrome. Which past medical history finding makes the client most at risk for this disease?
   1. Meningitis or encephalitis during the last 5 years
   2. Seizures or trauma to the brain within the last year
   3. Back injury or trauma to the spinal cord during the last 2 years
   4. Respiratory or gastrointestinal infection during the previous
718. A client with Guillain-Barré syndrome has ascending paralysis and is intubated and receiving mechanical ventilation. Which strategy should the nurse incorporate in the plan of care to help the client cope with this illness?
1. Giving client full control over care decisions and restricting visitors
2. Providing positive feedback and encouraging active range of motion
3. Providing information, giving positive feedback, and encouraging relaxation
4. Providing intravenously administered sedatives, reducing distractions, and limiting visitors

719. A client has a neurological deficit involving the limbic system. On assessment, which finding is specific to this type of deficit?
1. Is disoriented to person, place, and time.
2. Affect is flat, with periods of emotional lability.
3. Cannot recall what was eaten for breakfast today.
4. Demonstrates inability to add and subtract; does not know who is the president of the United States.

720. The nurse is instituting seizure precautions for a client who is being admitted from the emergency department. Which measures should the nurse include in planning for the client’s safety? Select all that apply.
1. Padding the side rails of the bed.
2. Placing an airway at the bedside.
3. Placing the bed in the high position.
4. Putting a padded tongue blade at the head of the bed.
5. Placing oxygen and suction equipment at the bedside.
6. Flushing the intravenous catheter to ensure that the site is patent.

721. The nurse is evaluating the status of a client who had a craniotomy 3 days ago. Which assessment finding would indicate that the client is developing meningitis as a complication of surgery?
1. A negative Kernig’s sign
2. Absence of nuchal rigidity
3. A positive Brudzinski’s sign
4. A Glasgow Coma Scale score of 15

722. The nurse has completed discharge instructions for a client with application of a halo device who sustained a cervical spinal cord injury. Which statement indicates that the client needs further clarification of the instructions?
1. “I will use a straw for drinking.”
2. “I will drive only during the daytime.”
3. “I will be careful because the device alters balance.”
4. I will wash the skin daily under the lamb’s wool liner of the vest.”

723. The nurse is admitting a client with Guillain-Barré syndrome to the nursing
The client has complaints of inability to move both legs and reports a tingling sensation above the waistline. Knowing the complications of the disorder, the nurse should bring which **most essential** items into the client’s room?

1. Nebulizer and pulse oximeter
2. Blood pressure cuff and flashlight
3. Nasal cannula and incentive spirometer
4. Electrocardiographic monitoring electrodes and intubation tray

**Answers**

704. **Answer:** 2

**Rationale:** Nailbed pressure tests a basic motor and sensory peripheral response. Cerebral responses to pain are tested using a sternal rub, placing upward pressure on the orbital rim, or squeezing the clavicle or sternocleidomastoid muscle.

**Test-Taking Strategy:** Focus on the **subject**, testing peripheral response to pain. The nailbeds are the most distal of all options and are therefore the most peripheral. Each of the other options may elicit a generalized response, but not a localized one.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Health Promotion and Maintenance

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Neurological

**Health Problem:** Adult Health: Neurological: Head injury/trauma

**Priority Concepts:** Intracranial Regulation; Pain

705. **Answer:** 2

**Rationale:** A change in vital signs may be a late sign of increased intracranial pressure. Trends include increasing temperature and blood pressure and decreasing pulse and respirations. Respiratory irregularities also may occur.

**Test-Taking Strategy:** Focus on the **subject**, signs of increased intracranial pressure. If you remember that the temperature rises, you are able to eliminate options 3 and 4. If you know that the client becomes bradycardic, or know that the blood pressure rises, you are able to select the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Neurological

**Health Problem:** Adult Health: Neurological: Head injury/trauma

**Priority Concepts:** Clinical Judgment; Intracranial Regulation

**Reference:** Lewis et al. (2017), pp. 1318-1319.

706. **Answer:** 4
**Rationale:** Activities that increase intrathoracic and intraabdominal pressures cause an indirect elevation of the intracranial pressure. Some of these activities include isometric exercises, Valsalva’s maneuver, coughing, sneezing, and blowing the nose. Exhaling during activities such as repositioning or pulling up in bed opens the glottis, which prevents intrathoracic pressure from rising.

**Test-Taking Strategy:** Focus on the subject, preventing elevations in intracranial pressure. Evaluate each option in terms of the tension it puts on the body. Doing so will help you eliminate each incorrect option systematically.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Evaluation

**Content Area:** Adult Health: Neurological

**Health Problem:** Adult Health: Neurological: Head injury/trauma

**Priority Concepts:** Client Education; Intracranial Regulation

707. **Answer:** 4

**Rationale:** Leakage of cerebrospinal fluid (CSF) from the ears or nose may accompany basilar skull fracture. CSF can be distinguished from other body fluids, because the drainage will separate into bloody and yellow concentric rings on dressing material, called a *halo sign*. The fluid also tests positive for glucose.

**Test-Taking Strategy:** Focus on the subject, the characteristics of CSF. Recall that CSF contains glucose, whereas other secretions, such as mucus, do not. Knowing that CSF separates into rings also will help you answer this question.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Neurological

**Health Problem:** Adult Health: Neurological: Head injury/trauma

**Priority Concepts:** Clinical Judgment; Intracranial Regulation

708. **Answer:** 1, 2, 4

**Rationale:** The most frequent cause of autonomic dysreflexia is a distended bladder. Straight catheterization should be done every 4 to 6 hours (catheterization every 12 hours is too infrequent), and urinary catheters should be checked frequently to prevent kinks in the tubing. Constipation and fecal impaction are other causes, so maintaining bowel regularity is important. Ensuring a bowel movement once a week is much too infrequent. Other causes include stimulation of the skin from tactile, thermal, or painful stimuli. The nurse administers care to minimize risk in these areas.

**Test-Taking Strategy:** Focus on the subject, preventing autonomic dysreflexia. Remember that autonomic dysreflexia is caused by noxious stimuli to the bowel, bladder, or skin. With this in mind, you can eliminate easily each of the incorrect options.
Rationale: Resolution of spinal shock is occurring when there is return of reflexes (especially flexors to noxious cutaneous stimuli), a state of hyper-reflexia rather than flaccidity, and reflex emptying of the bladder.

Test-Taking Strategy: Recall that spinal shock is characterized by the loss of movement of skeletal muscles, loss of bowel or bladder wall function, and depressed reflex action. Return of any of these indicates that spinal shock is beginning to resolve. Note that options 1, 2, and 4 are comparable or alike, indicating the presence of reflexes.

Rationale: Nursing actions during a seizure include providing for privacy, loosening restrictive clothing, removing the pillow and raising padded side rails in the bed, and placing the client on 1 side with the head flexed forward, if possible, to allow the tongue to fall forward and facilitate drainage. The limbs are never restrained because the strong muscle contractions could cause the client harm. If the client is not in bed when seizure activity begins, the nurse lowers the client to the floor, if possible; protects the head from injury; and moves furniture that may injure the client.

Test-Taking Strategy: Focus on the subject, interventions during a seizure. Think about ethical and legal issues to eliminate option 5. Next, evaluate this question from the perspective of causing possible harm. No harm can come to the client from any of the options except for restraining the limbs. Remember to avoid restraints.
711. Answer: 1, 2, 4

**Rationale:** Hemiparesis is a weakness of one side of the body that may occur after a stroke. It involves weakness of the face and tongue, arm, and leg on one side. These clients are also aphasic, unable to discriminate words and letters. They are generally very cautious and get anxious when attempting a new task. Complete bilateral paralysis does not occur in hemiparesis. The client with right-sided hemiparesis has weakness of the right arm and leg and needs assistance with feeding, bathing, and ambulating.

**Test-Taking Strategy:** Focus on the subject, right-sided hemiparesis. Recalling that hemiparesis indicates weakness on one side of the body and focusing on the subject will direct you to the correct option. Also, noting the word *complete* in the question will assist you in answering correctly.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Neurological

**Health Problem:** Adult Health: Neurological: Stroke

**Priority Concepts:** Functional Ability; Intracranial Regulation

**Reference:** Lewis et al. (2017), p. 1345.

712. Answer: 4

**Rationale:** Homonymous hemianopsia is loss of half of the visual field. The client with homonymous hemianopsia should have objects placed in the intact field of vision, and the nurse also should approach the client from the intact side. The nurse instructs the client to scan the environment to overcome the visual deficit and does client teaching from within the intact field of vision. The nurse encourages the use of personal eyeglasses, if they are available.

**Test-Taking Strategy:** Focus on the subject, homonymous hemianopsia. Eliminate options 2 and 3 first because they are comparable or alike. Recalling the definition of homonymous hemianopsia will direct you easily to the correct option.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Evaluation

**Content Area:** Adult Health: Neurological

**Health Problem:** Adult Health: Neurological: Stroke

**Priority Concepts:** Intracranial Regulation; Safety

**Reference:** Lewis et al. (2017), p. 1362.

713. Answer: 4

**Rationale:** Clients are evaluated as coping successfully with lifestyle changes after a stroke if they make appropriate lifestyle alterations, use the assistance of others, and have appropriate social interactions. Options 1 and 2 are not adaptive behaviors; option 3 indicates a not yet successful attempt to adapt.

**Test-Taking Strategy:** Note the strategic word, *most*, and focus on the subject,
indications that a client who has had a stroke is adapting most successfully. Options 1 and 2 are behaviors that may be expected in the client with a stroke, but they are not adaptive responses. Instead, they are a result of the insult to the brain. Options 3 and 4 indicate that the client is trying to adapt, but the correct option has the best outcome.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Adult Health: Neurological  
**Health Problem:** Adult Health: Neurological: Stroke  
**Priority Concepts:** Coping; Functional Ability  

714. **Answer:** 1

**Rationale:** Clients with myasthenia gravis are taught to space out activities over the day to conserve energy and restore muscle strength. Taking medications correctly to maintain blood levels that are not too low or too high is important. Muscle-strengthening exercises are not helpful and can fatigue the client. Overeating is a cause of exacerbation of symptoms, as is exposure to heat, crowds, erratic sleep habits, and emotional stress.

**Test-Taking Strategy:** Note the strategic words, most effective. Recalling that the common causes of myasthenic and cholinergic crises are undermedication and overmedication, respectively, will assist you in eliminating each of the incorrect options. No other option would prevent both of those complications.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Adult Health: Neurological  
**Health Problem:** Adult Health: Neurological: Myasthenia gravis  
**Priority Concepts:** Client Education; Safety  

715. **Answer:** 4

**Rationale:** The client with Parkinson’s disease should be instructed regarding safety measures in the home. The client should use her or his walker as support to get to the bathroom because of bradykinesia. The client should sit down to put on pants and shoes to prevent falling. The client should exercise every day in the morning when energy levels are highest. The client should have all loose rugs in the home removed to prevent falling.

**Test-Taking Strategy:** Note the strategic words, need for further teaching. These words indicate a negative event query and the need to select the incorrect client statement as the answer. Recall that clients with Parkinson’s disease are at risk for falls.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Neurological  
**Health Problem:** Adult Health: Neurological: Parkinson’s disease  
**Priority Concepts:** Client Education; Safety  

**716. Answer:** 4

**Rationale:** Facial pain can be minimized by using cotton pads to wash the face and using room temperature water. The client should chew on the unaffected side of the mouth, eat a soft diet, and take in foods and beverages at room temperature. If brushing the teeth triggers pain, an oral rinse after meals may be helpful instead.

**Test-Taking Strategy:** Note the **strategic words**, *needs further teaching*. These words indicate a **negative event query** and ask you to select an option that is incorrect. Recall that the pain of trigeminal neuralgia is triggered by mechanical or thermal stimuli. Very hot or cold foods are likely to trigger the pain, not relieve it.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Neurological  
**Health Problem:** Adult Health: Neurological: Trigeminal neuralgia  
**Priority Concepts:** Client Education; Pain  
**Reference:** Lewis et al. (2017), pp. 1437-1438.

**717. Answer:** 4

**Rationale:** Guillain-Barré syndrome is a clinical syndrome of unknown origin that involves cranial and peripheral nerves. Many clients report a history of respiratory or gastrointestinal infection in the 1 to 4 weeks before the onset of neurological deficits. On occasion, the syndrome can be triggered by vaccination or surgery.

**Test-Taking Strategy:** Note the **strategic word**, *most*. Use knowledge regarding the causes related to this disorder. Remember that a recent history of respiratory or gastrointestinal infection is a predisposing factor.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Neurological  
**Health Problem:** Adult Health: Neurological: Guillain-Barré syndrome  
**Priority Concepts:** Clinical Judgment; Infection  
**Reference:** Lewis et al. (2017), pp. 1440-1441.

**718. Answer:** 3

**Rationale:** The client with Guillain-Barré syndrome experiences fear and anxiety from the ascending paralysis and sudden onset of the disorder. The nurse can alleviate these fears by providing accurate information about the client’s condition,
giving expert care and positive feedback to the client, and encouraging relaxation and distraction. The family can become involved with selected care activities and provide diversion for the client as well.

**Test-Taking Strategy:** Focus on the **subject**, helping a client cope with illness. Option 1 should be eliminated first, because it is not practical to think that the client would want full control over all care decisions. The client who is paralyzed cannot participate in active range of motion, which eliminates option 2. From the remaining options, the correct option is more beneficial in helping the client cope.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Caring  
**Content Area:** Adult Health: Neurological  
**Health Problem:** Adult Health: Neurological: Guillain-Barré syndrome  
**Priority Concepts:** Caregiving; Coping  

719. **Answer:** 2

**Rationale:** The limbic system is responsible for feelings (affect) and emotions. Calculation ability and knowledge of current events relate to function of the frontal lobe. The cerebral hemispheres, with specific regional functions, control orientation. Recall of recent events is controlled by the hippocampus.

**Test-Taking Strategy:** Focus on the **subject**, neurological deficit of the limbic system. It is necessary to recall that the limbic system is responsible for feelings and emotions to direct you to the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Neurological  
**Health Problem:** N/A  
**Priority Concepts:** Clinical Judgment; Intracranial Regulation  
**Reference:** Lewis et al. (2017), pp. 79, 1298.

720. **Answer:** 1, 2, 5, 6

**Rationale:** Seizure precautions may vary from agency to agency, but they generally have some common features. Usually, an airway, oxygen, and suctioning equipment are kept available at the bedside. The side rails of the bed are padded, and the bed is kept in the lowest position. The client has an intravenous access in place to have a readily accessible route if antiseizure medications must be administered, and as part of the routine assessment the nurse should be checking patency of the catheter. The use of padded tongue blades is highly controversial, and they should not be kept at the bedside. Forcing a tongue blade into the mouth during a seizure more likely will harm the client who bites down during seizure activity. Risks include blocking the airway from improper placement, chipping the client’s teeth, and subsequent risk of aspirating tooth fragments. If the client has an aura before the seizure, it may give the nurse enough time to place an oral airway before  

2061
seizure activity begins.

**Test-Taking Strategy:** Focus on the subject, seizure precautions. Evaluate this question from the perspective of causing possible harm. No harm can come to the client from any of the options except for placing the bed in the high position and using a tongue blade.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Planning

**Content Area:** Adult Health: Neurological

**Health Problem:** Adult Health: Neurological: Seizure disorder/epilepsy

**Priority Concepts:** Intracranial Regulation; Safety

**Reference:** Lewis et al. (2017), p. 1378.

721. **Answer:** 3

**Rationale:** Signs of meningeal irritation compatible with meningitis include nuchal rigidity, a positive Brudzinski’s sign, and positive Kernig’s sign. Nuchal rigidity is characterized by a stiff neck and soreness, which is especially noticeable when the neck is flexed. Kernig’s sign is positive when the client feels pain and spasm of the hamstring muscles when the leg is fully flexed at the knee and hip. Brudzinski’s sign is positive when the client flexes the hips and knees in response to the nurse gently flexing the head and neck onto the chest. A Glasgow Coma Scale score of 15 is a perfect score and indicates that the client is awake and alert, with no neurological deficits.

**Test-Taking Strategy:** Focus on the subject, a client’s diagnosis of meningitis. You can eliminate options 1, 2, and 4 because they are comparable or alike and are normal findings.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Neurological

**Health Problem:** Adult Health: Neurological: Inflammation/infections

**Priority Concepts:** Clinical Judgment; Intracranial Regulation

722. **Answer:** 2

**Rationale:** The halo device alters balance and can cause fatigue because of its weight. The client should cleanse the skin daily under the vest to protect the skin from ulceration and should avoid the use of powder or lotions. The liner should be changed if odor becomes a problem. The client should have food cut into small pieces to facilitate chewing and use a straw for drinking. Pin care is done as instructed. The client cannot drive at all, because the device impairs the range of vision.

**Test-Taking Strategy:** Note the strategic words, needs further clarification. These words indicate a negative event query and ask you to select an option that is incorrect. Visualize this device to answer correctly. The inability to turn the head
without turning the torso would contraindicate driving. Also note the closed-ended word “only” in the correct option.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Adult Health: Neurological

**Health Problem:** Adult Health: Neurological: Spinal cord injury

**Priority Concepts:** Client Education; Safety

**Reference:** Lewis et al. (2017), pp. 1427-1428.

723. **Answer:** 4

**Rationale:** The client with Guillain-Barré syndrome is at risk for respiratory failure because of ascending paralysis. An intubation tray should be available for use. Another complication of this syndrome is cardiac dysrhythmias, which necessitates the use of electrocardiographic monitoring. Because the client is immobilized, the nurse should assess for deep vein thrombosis and pulmonary embolism routinely. Although items in the incorrect options may be used in care, they are not the most essential items from the options provided.

**Test-Taking Strategy:** Note the **strategic words**, most essential. With an ascending paralysis, the client is at risk for involvement of respiratory muscles and subsequent respiratory failure. The correct option is the only one that includes an intubation tray, which would be needed if the client’s status deteriorated to needing intubation and mechanical ventilation. This option most directly addresses the airway.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Adult Health: Neurological

**Health Problem:** Adult Health: Neurological: Guillain-Barré syndrome

**Priority Concepts:** Clinical Judgment; Safety

**Reference:** Lewis et al. (2017), pp. 1440-1441.
CHAPTER 59

Neurological Medications

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts

Intracranial Regulation; Pain

I. Antimyasthenic Medications
   A. Description
      1. Antimyasthenic medications, also called anticholinesterase medications, relieve muscle weakness associated with myasthenia gravis by blocking acetylcholine breakdown at the neuromuscular junction.
      2. These are used to treat or diagnose myasthenia gravis or to distinguish cholinergic crisis from myasthenic crisis.
      3. Neostigmine bromide and pyridostigmine are used to control myasthenic symptoms.
      4. Edrophonium is used to diagnose myasthenia gravis and to distinguish cholinergic crisis from myasthenic crisis.
   
   B. Medications (Box 59-1)
   
   C. Side and adverse effects: Cholinergic crisis (Box 59-2)
   
   D. Interventions
      1. Assess neuromuscular status, including reflexes, muscle strength, and gait.
      2. Monitor the client for signs and symptoms of medication overdose (cholinergic crisis) and underdose (myasthenic crisis).
      3. Instruct the client to take medications on time to maintain therapeutic blood level, thus preventing weakness, because weakness can impair the client’s ability to breathe and swallow.
      4. Instruct the client to take the medication with a small amount of food to prevent gastrointestinal symptoms.
      5. Instruct the client to eat a meal 45 to 60 minutes after taking medications to decrease the risk for aspiration.
6. Instruct the client to wear a MedicAlert bracelet.
7. Note that antimiasthenic therapy is lifelong therapy.
8. Evaluate for medication effectiveness, which is based on the improvement of neuromuscular symptoms or strength without cholinergic signs and symptoms.
9. When administering edrophonium, have emergency resuscitation equipment on hand and atropine sulfate available for cholinergic crisis.

E. Edrophonium test (may be known as the Tensilon test)

1. Edrophonium is injected intravenously.
2. The edrophonium test can cause bronchospasm, laryngospasm, hypotension, bradycardia, and cardiac arrest.
3. Atropine sulfate is the antidote for overdose.
4. Diagnosis of myasthenia gravis: Most myasthenic clients will show a significant improvement in muscle tone within 30 to 60 seconds after injection, and the muscle improvement lasts 4 to 5 minutes.
5. The edrophonium test is also used to diagnose cholinergic crisis (overdose with anticholinesterase) or myasthenic crisis (undermedication).
   a. In cholinergic crisis, muscle tone does not improve after the administration of edrophonium, and muscle twitching may be noted around the eyes and face.
   b. An edrophonium injection temporarily worsens the condition when a client is in cholinergic crisis (negative edrophonium test).
   c. An edrophonium injection temporarily improves the condition when the client is in myasthenic crisis (positive edrophonium test).

II. Multiple Sclerosis Medications
   A. Description

1. Medication therapy is aimed at modifying the disease, treating acute episodes or relapses, and treating symptoms.
2. Disease-modifying medications decrease the frequency and severity of relapses, reduce brain lesions, increase future functional capability, and increase overall quality of life.
3. The 2 main groups of disease-modifying medications are immunomodulators and immunosuppressants (Box 59-3).
4. Treating acute episodes usually consists of giving a
high-dose glucocorticoid intravenously to suppress inflammation or giving gamma globulin intravenously.

5. Treating symptoms of multiple sclerosis can be done with a variety of medications, and the medication can be changed if unfavorable effects occur.
6. Box 59-4 identifies medications commonly used to treat symptoms.

B. Side and adverse effects
   1. Immunomodulators: Flu-like reactions, hepatotoxicity, myelosuppression, injection site reactions, depression, and neutralizing antibodies.
   2. Immunosuppressants: Myelosuppression, cardiotoxicity, fetal harm, reversible hair loss, injury to the gastrointestinal mucosa, nausea and vomiting, and menstrual irregularities.

III. Antiparkinsonian Medications
   A. Description
   1. Antiparkinsonian medications restore the balance of the neurotransmitters acetylcholine and dopamine in the central nervous system (CNS), decreasing the signs and symptoms of Parkinson’s disease to maximize the client’s functional abilities.
   2. These medications include the dopaminergics, which stimulate the dopamine receptors; the anticholinergics, which block the cholinergic receptors; and the catechol-O-methyltransferase inhibitors, which inhibit the metabolism of dopamine in the periphery.
   B. Dopaminergic medications
      1. Description
         a. Dopaminergic medications stimulate the dopamine receptors and increase the amount of dopamine available in the CNS or enhance neurotransmission of dopamine.
         b. Dopaminergic medications are contraindicated in clients with cardiac, renal, or psychiatric disorders.

   Carbidopa-levodopa taken with a monoamine oxidase inhibitor antidepressant can cause a hypertensive crisis.
a. Dyskinesia
b. Involuntary body movements
c. Chest pain
d. Nausea and vomiting
e. Urinary retention
f. Constipation
g. Sleep disturbances, insomnia, or periods of sedation
h. Orthostatic hypotension and dizziness
i. Confusion
j. Mood changes, especially depression
k. Hallucinations
l. Dry mouth

4. Interventions

a. Assess vital signs.
b. Assess for risk of injury.
c. Instruct the client to take the medication with food if nausea or vomiting occurs.
d. Assess for signs and symptoms of parkinsonism such as rigidity, tremors, akinesia, bradykinesia, a stooped forward posture, shuffling gait, and masked facies.
e. Monitor for signs of dyskinesia.
f. Instruct the client to report side and adverse effects and symptoms of dyskinesia.
g. Monitor the client for improvement in signs and symptoms of parkinsonism.
h. Instruct the client to change positions slowly to minimize orthostatic hypotension.
i. Instruct the client not to discontinue the medication abruptly.
j. Instruct the client to avoid alcohol.
k. Inform the client that urine or perspiration may be discolored and that this is harmless but may stain the clothing.
l. Advise the client with diabetes mellitus that glucose testing should not be done by urine testing, because the results will not be reliable.
m. Instruct the client taking carbidopa-levodopa to divide the total daily prescribed protein intake among all meals of the day; high-protein diets
interfere with medication availability to the CNS.

n. When administering carbidopa-levodopa, instruct the client to avoid excessive vitamin $B_6$ intake to prevent medication reactions.

C. Anticholinergic medications
   1. Description
      a. Anticholinergic medications block the cholinergic receptors in the CNS, thereby suppressing acetylcholine activity.
      b. They reduce the tremors and drooling but have a minimal effect on the bradykinesia, rigidity, and balance abnormalities.
      c. They are contraindicated in clients with glaucoma.
      d. The client with chronic obstructive lung disease can develop dry, thick mucous secretions.

2. Medications (see Box 59-5)

3. Side and adverse effects
   a. Blurred vision
   b. Dryness of the nose, mouth, throat, and respiratory secretions
   c. Increased pulse rate, palpitations, and dysrhythmias
   d. Constipation
   e. Urinary retention
   f. Restlessness, confusion, depression, and hallucinations
   g. Photophobia

4. Interventions
   a. Monitor vital signs.
   b. Assess for risk of injury.
   c. Monitor the client for improvement in signs and symptoms.
   d. Assess the client’s bowel and urinary function and monitor for urinary retention, constipation, and paralytic ileus.
   e. Monitor for involuntary movements.
   f. Encourage the client to avoid alcohol,
smoking, caffeine, and acetylsalicylic acid to decrease gastric acidity.

**g.** Instruct the client to consult with a primary health care provider (PHCP) before taking any nonprescription medications.

**h.** Instruct the client to minimize dry mouth by increasing fluid intake and using ice chips, hard candy, or gum.

**i.** Instruct the client to prevent constipation by increasing fluids and fiber in the diet.

**j.** Instruct the client to use sunglasses in direct sunlight because of possible photophobia.

**k.** Instruct the client to have routine eye examinations to assess intraocular pressure.

*If an anticholinergic medication is discontinued abruptly, the signs and symptoms of parkinsonism, such as rigidity, tremors, akinesia, bradykinesia, stooped forward posture, shuffling gait, and masked facies, may be intensified.*

**IV. Antiseizure Medications**

**A. Description**

1. Antiseizure medications are used to depress abnormal neuronal discharges and prevent the spread of seizures to adjacent neurons.

2. These should be used with caution in clients taking anticoagulants, acetylsalicylic acid, sulfonamides, cimetidine, and antipsychotic medications.

3. Absorption is decreased with the use of antacids, calcium preparations, and antineoplastic medications.

**B. Interventions for clients on antiseizure medications**

1. Initiate seizure precautions.
3. Monitor liver and renal function tests and medication blood serum levels (*Table 59-1*).
4. Monitor for signs of medication toxicity, which would include CNS depression, ataxia, nausea, vomiting, drowsiness, dizziness, restlessness, and visual disturbances.
5. If a seizure occurs, assess seizure activity, including location and duration (see Chapter 58 for management of seizures).

6. Protect the client from hazards in the environment during a seizure.

C. Client education (Box 59-6)

D. Hydantoins: Fosphenytoin, phenytoin

1. Hydantoins are used to treat partial and generalized tonic-clonic seizures.
2. Phenytoin is also used to treat dysrhythmias.
3. Side and adverse effects
   a. Gingival hyperplasia (redden gums that bleed easily)
   b. Slurred speech
   c. Confusion
   d. Sedation and drowsiness
   e. Nausea and vomiting
   f. Blurred vision and nystagmus
   g. Headaches
   h. Blood dyscrasias: Decreased platelet count and decreased white blood cell count
   i. Elevated blood glucose level

4. Interventions
   a. Alopecia or hirsutism
   b. Rash or pruritus
   c. Tube feedings may interfere with the absorption of the enteral form of phenytoin and diminish the effectiveness of the medication; therefore, feedings should be scheduled as far as possible away from the time of phenytoin administration.
   d. Monitor therapeutic serum levels to assess for toxicity.
   e. Monitor for signs of toxicity.
   f. When administering phenytoin intravenously, dilute in normal saline, because dextrose causes the medication to precipitate.
   g. When administering phenytoin intravenously, infuse with an inline filter and no faster than 25 to 50 mg/minute; otherwise, a decrease in blood pressure and cardiac
dysrhythmias could occur.
h. Assess for ataxia (staggering gait).
i. Instruct the client to consult with the PHCP before taking other medications to ensure compatibility with anticonvulsants.

Phenytoin must be given slowly to prevent hypotension and cardiac dysrhythmias. Also, it may decrease the effectiveness of some birth control pills and may cause teratogenic effects, if taken during pregnancy.

E. Barbiturates: Amobarbital, phenobarbital
1. Barbiturates are used for tonic-clonic seizures and acute episodes of seizures caused by status epilepticus.
2. Barbiturates also may be used as adjuncts to anesthesia.
3. Side and adverse effects
   a. Sedation, ataxia, and dizziness during initial treatment
   b. Mood changes
   c. Hypotension
   d. Respiratory depression
   e. Tolerance to the medication

F. Benzodiazepines: Clonazepam, clorazepate, diazepam, lorazepam
1. Benzodiazepines are used to treat absence seizures.
2. Diazepam and lorazepam are used to treat status epilepticus, anxiety, and skeletal muscle spasms.
3. Clorazepate is used as adjunctive therapy for partial seizures.
4. Side and adverse effects
   a. Sedation, drowsiness, dizziness, blurred vision
   b. For intravenous injection, administer slowly to prevent bradycardia.
   c. Medication tolerance and dependency
   d. Blood dyscrasias: Decreased platelet count and decreased white blood cell count
   e. Hepatotoxicity
Flumazenil reverses the effects of benzodiazepines. It should not be administered to clients with increased intracranial pressure or status epilepticus who were treated with benzodiazepines, because these problems may recur with reversal.

G. Succinimides: Ethosuximide, methsuximide
1. Succinimides are used to treat absence seizures.
2. Side and adverse effects
   a. Anorexia, nausea, vomiting
   b. Blood dyscrasias

H. Valproates: Valproic acid, divalproex sodium
1. Valproates are used to treat tonic-clonic, partial, and myoclonic seizures.
2. Side and adverse effects
   a. Transient nausea, vomiting, and indigestion
   b. Sedation, drowsiness, and dizziness
   c. Pancreatitis
   d. Blood dyscrasias: Decreased platelet count and decreased white blood cell count
   e. Hepatotoxicity

I. Iminostilbenes
1. Iminostilbenes are used to treat seizure disorders that have not responded to other anticonvulsants (Box 59-7).
2. Iminostilbenes are also used to treat trigeminal neuralgia.
3. Side and adverse effects
   a. Drowsiness
   b. Dizziness
   c. Nausea and vomiting, dry mouth
   d. Constipation or diarrhea
   e. Rash
   f. Visual abnormalities
   g. Blood dyscrasias, agranulocytosis
   h. Headache

V. Central Nervous System Stimulants
A. Description
1. Amphetamines and caffeine stimulate the cerebral cortex of the brain (Box 59-8).
2. Amphetamines have a high potential for abuse.
3. Analactics and caffeine act on the brainstem and medulla to stimulate respiration.
4. Anorexiants act on the cerebral cortex and
hypothesis to suppress appetite (Box 59-9).
5. CNS stimulants are used to treat narcolepsy and attention-deficit/hyperactivity disorders and are used as adjunctive therapy for exogenous obesity.

B. Side and adverse effects

1. Irritability
2. Restlessness
3. Tremors
4. Insomnia
5. Heart palpitations
6. Tachycardia and dysrhythmias
7. Hypertension
8. Dry mouth
9. Anorexia and weight loss
10. Abdominal cramping
11. Diarrhea or constipation
12. Hepatic failure
13. Psychoses
14. Impotence
15. Dependence and tolerance

C. Interventions

1. Monitor vital signs.
2. Assess mental status.
3. Document the degree of inattention, impulsivity, hyperactivity, and periods of sleepiness.
5. Monitor complete blood count and white blood cell and platelet counts before and during therapy.
6. Monitor for side and adverse effects.
7. Monitor sleep patterns.
8. Monitor for withdrawal symptoms such as nausea, vomiting, weakness, and headache.
9. Instruct the client to take the medication before meals.
10. Instruct the client to avoid foods and beverages containing caffeine to prevent additional stimulation.
11. Instruct the client not to chew or crush long-acting forms of the medications.
12. Instruct the client to read labels on over-the-counter products, because they may contain caffeine.
13. Instruct the client to avoid alcohol.
14. Instruct the client not to discontinue the medication abruptly (can produce extreme fatigue and depression).
15. Instruct the client to take the last daily dose of the CNS stimulant at least 6 hours before bedtime to prevent

17. If a child is taking a CNS stimulant, instruct the parents to notify the school nurse.

18. Monitor for calming effects of CNS stimulants within 3 to 4 weeks on children with attention-deficit/hyperactivity disorder.

19. Monitor growth in the child on long-term therapy with methylphenidate or other medications to treat attention-deficit/hyperactivity disorder.

VI. Nonopioid Analgesics

A. Nonsteroidal antiinflammatory drugs (NSAIDs; Box 59-10)

1. Description

a. NSAIDs are acetylsalicylic acid and acetylsalicylic acid–like medications that inhibit the synthesis of prostaglandins.

b. The medications act as an analgesic to relieve pain, an antipyretic to reduce body temperature, and an anticoagulant to inhibit platelet aggregation.

c. NSAIDs are used to relieve inflammation and pain and to treat rheumatoid arthritis, bursitis, tendinitis, osteoarthritis, and acute gout.

d. NSAIDs are contraindicated in clients with hypersensitivity or liver or renal disease.

e. Clients taking anticoagulants should not take acetylsalicylic acid or NSAIDs.

f. Acetylsalicylic acid and an NSAID should not be taken together, because aspirin decreases the blood level and effectiveness of the NSAID and can increase the risk of bleeding.

g. NSAIDs can increase the effects of warfarin, sulfonamides, cephalosporins, and phenytoin.

h. Hypoglycemia can result if ibuprofen is
taken with insulin or an oral hypoglycemic medication.

i. A high risk of toxicity exists if ibuprofen is taken concurrently with calcium channel blockers.

Adolescents and children with flu symptoms, viral illnesses, and varicella should not take acetylsalicylic acid because of the risk of Reye’s syndrome.

2. Side and adverse effects (Box 59-11)

3. Interventions

   a. Assess client for allergies.
   b. Obtain a medication history on the client.
   c. Assess for history of gastric upset or bleeding or liver or renal disease.
   d. Assess the client for gastrointestinal upset during medication administration.
   e. Monitor for edema.
   f. Monitor the serum salicylate (acetylsalicylic acid) level when the client is taking high doses.
   g. Monitor for signs of bleeding such as tarry stools, bleeding gums, petechiae, ecchymosis, and purpura.
   h. Instruct the client to take the medication with milk, or food.
   i. An enteric-coated or buffered form of acetylsalicylic acid can be taken to decrease gastric distress.
   j. Instruct the client that enteric-coated tablets cannot be crushed or broken.
   k. Clients taking acetylsalicylic acid should sit upright for 20 to 30 minutes after taking the dose.
   l. Advise the client to inform other health care professionals if they are taking high doses of acetylsalicylic acid.
   m. Note that acetylsalicylic acid should be discontinued 3 to 7 days before surgery as prescribed to reduce the risk of bleeding.
   n. Instruct the client to avoid alcoholic beverages.
B. Acetaminophen

1. Description
   a. Acetaminophen inhibits prostaglandin synthesis.
   b. Used to decrease pain and fever
   c. Should not be taken if liver dysfunction exists

2. Side and adverse effects
   a. Anorexia, nausea, vomiting
   b. Rash
   c. Hypoglycemia
   d. Oliguria
   e. Hepatotoxicity

3. Interventions
   a. Monitor vital signs.
   b. Assess client for history of liver and renal dysfunction, alcoholism, and malnutrition.
   c. Monitor for hepatic damage, which includes nausea, vomiting, diarrhea, and abdominal pain.
   d. Monitor liver enzyme test results.
   e. Instruct the client that self-medication should not be used longer than 10 days for an adult and 5 days for a child.
   f. Note that the antidote for acetaminophen is acetylcysteine.
   g. Evaluate for the effectiveness of the medication.

VII. Opioid Analgesics

A. Description
   1. Opioid analgesics suppress pain impulses but can suppress respiration and coughing by acting on the respiratory and cough center in the medulla of the brainstem.
   2. They can produce euphoria and sedation and can cause physical dependence.
3. Used for relief of mild, moderate, or severe pain

B. Medications (Box 59-12)

1. Codeine
   a. Codeine also is an effective cough suppressant at low doses.
   b. It can cause constipation.

2. Hydromorphone
   a. Hydromorphone can decrease respirations.
   b. It can cause constipation.

3. Meperidine
   a. Meperidine can cause hypotension, dizziness, and urinary retention.
   b. Is not commonly prescribed but may be used for acute pain and as a preoperative medication
   c. May lead to increased intracranial pressure (ICP) in clients with head injuries
   d. Contraindicated in clients with head injuries and increased ICP, respiratory disorders, hypotension, shock, and severe hepatic and renal disease and in clients taking monoamine oxidase inhibitors
   e. Should not be taken with alcohol or a sedative-hypnotic, because it may increase the CNS depression
   f. Should be used cautiously in children and adults with a seizure disorder or a history of seizures, because it decreases the seizure threshold

4. Morphine
   a. Morphine can cause respiratory depression, orthostatic hypotension, and constipation.
   b. May cause nausea and vomiting because of increased vestibular sensitivity
   c. Used for acute pain caused by myocardial infarction or cancer, for dyspnea caused by pulmonary edema, for surgery, and as a preoperative medication
   d. Is contraindicated in clients with severe
respiratory disorders; head injuries; increased ICP; severe renal, hepatic, or pulmonary disease; or seizure activity.
e. Morphine is used with caution in clients with blood loss or shock.

Respiratory depression is the priority concern with morphine.

5. Nalbuphine is preferable for treating the pain of a myocardial infarction because it reduces the oxygen needs of the heart without reducing blood pressure.

6. Methadone
   a. Dilute doses of oral concentrate with at least 90 mL of water.
   b. Dilute dispersible tablets in at least 120 mL of water, orange juice, or acidic fruit beverage.
   c. Methadone is used as a replacement medication for opiate dependence and to facilitate withdrawal.

7. Hydrocodone/homatropine frequently is used for cough suppression.

C. Interventions for opioid analgesics

1. Monitor vital signs.
2. Assess the client thoroughly before administering pain medication.
3. Initiate nursing measures such as massage, distraction, deep breathing and relaxation exercises, the application of heat or cold as prescribed, and providing care and comfort along with administering the opioid analgesic.
4. Administer medications 30 to 60 minutes before painful activities.
5. Monitor respiratory rate and, if the rate is less than 12 breaths per minute in an adult, withhold the medication unless ventilatory support is being provided or the client has terminal disease (as prescribed).
6. Monitor pulse and, if bradycardia develops, withhold the dose and notify the PHCP.
7. Monitor blood pressure for hypotension.
8. Auscultate breath sounds, because opioid analgesics suppress the cough reflex.
9. Encourage activities such as turning, deep breathing,
and incentive spirometry to prevent atelectasis and pneumonia.
10. Monitor level of consciousness.
11. Initiate safety precautions such as a night light and supervised ambulation.
12. Monitor intake and output.
14. Instruct the client to take oral doses with milk or a snack to reduce gastric irritation.
15. Instruct the client to avoid alcohol.
16. Instruct the client to avoid activities that require alertness.
17. Assess bowel function for constipation, abdominal distention, and decreased peristalsis.
18. Evaluate the effectiveness of medication.
19. Have an opioid antagonist, oxygen, and resuscitation equipment available.

D. Morphine

1. Side and adverse effects
   a. Respiratory depression
   b. Orthostatic hypotension
   c. Urinary retention
   d. Nausea and vomiting
   e. Constipation
   f. Sedation, confusion, and hallucinations
   g. Cough suppression
   h. Reduction in pupillary size
   i. Miosis

2. Interventions
   a. Have naloxone available for overdose.
   b. Assess vital signs and level of consciousness.
   c. Compare rate and depth of respirations to baseline.
   d. Withhold the medication if the respiratory rate is less than 12 breaths per minute; respirations of less than 10 breaths per minute can indicate respiratory distress.
   e. Monitor urinary output, which should be at least 30 mL/hr.
   f. Monitor bowel sounds for decreased peristalsis, because constipation can occur.
g. Monitor for pupil changes because pinpoint pupils can indicate morphine overdose.

h. Avoid alcohol or CNS depressants because they can cause respiratory depression.

i. Instruct the client to report dizziness or difficulty breathing.

j. If taking sustained-release morphine, the client may need short-acting opioid doses for breakthrough pain.

k. To administer morphine intravenously, dilute in at least 5 mL of sterile water (per agency procedure) for injection and administer slowly over 4 to 5 minutes.

l. Explain to the client and family about administration and the side and adverse effects of the medication.

E. Meperidine

1. Side and adverse effects

   a. Respiratory depression
   b. Hypotension and dizziness
   c. Tachycardia
   d. Drowsiness and confusion
   e. Constipation
   f. Urinary retention
   g. Nausea and vomiting
   h. Seizures
   i. Tremors

2. Interventions

   a. Monitor vital signs.
   b. Monitor for respiratory depression and hypotension.
   c. Have naloxone available for overdose.
   d. Monitor for urinary retention.
   e. Monitor bowel sounds and for constipation.
   f. To administer meperidine intravenously, dilute in at least 5 mL of sterile water or normal saline (per agency procedure) for injection and administer the dose over 4 to 5 minutes.
VIII. Opioid Antagonists
   A. Opioid antagonists (Box 59-13) are used to treat respiratory depression from opioid overdose.

B. Interventions
   1. Monitor blood pressure, pulse, and respiratory rate every 5 minutes initially, tapering to every 15 minutes, and then every 30 minutes until the client is stable.
   2. Place the client on a cardiac monitor and monitor cardiac rhythm.
   3. Auscultate breath sounds.
   4. Have resuscitation equipment available.
   5. Do not leave the client unattended.
   6. Monitor the client closely for several hours, because when the effects of the antagonist wear off, the client may again display signs of opioid overdose.

IX. Osmotic Diuretics
   A. Description
      1. Osmotic diuretics increase osmotic pressure of the glomerular filtrate, inhibiting reabsorption of water and electrolytes.
      2. They are used for oliguria and to prevent kidney failure, decrease ICP, and decrease intraocular pressure in clients with narrow-angle glaucoma.
      3. Mannitol is used with chemotherapy to induce diuresis.

B. Side and adverse effects
   1. Fluid and electrolyte imbalances
   2. Pulmonary edema from the rapid shifts of fluid
   3. Nausea and vomiting
   4. Headache
   5. Tachycardia from the rapid fluid loss
   6. Hyponatremia and dehydration

C. Interventions
   1. Monitor vital signs.
   4. Monitor electrolyte levels.
   5. Monitor lungs and heart sounds for signs of pulmonary edema.
   6. Monitor for signs of dehydration.
   7. Monitor neurological status.
   8. Monitor for increased intraocular pressure.
   9. Assess for signs of decreasing ICP if appropriate.
10. Change the client’s position slowly to prevent orthostatic hypotension.
11. Monitor for crystallization in the vial of mannitol before administering the medication; if crystallization is noted, do not administer the medication from that vial.

---

**Box 59-1**

**Antimyasthenic Medications**

- Edrophonium chloride
- Neostigmine bromide
- Pyridostigmine

---

**Box 59-2**

**Signs of Cholinergic Crisis**

- Abdominal cramps
- Nausea, vomiting, and diarrhea
- Pupillary miosis
- Hypotension and dizziness
- Increased bronchial secretions
- Increased tearing and salivation
- Increased perspiration
- Bronchospasm, wheezing, and bradycardia

---

**Box 59-3**

**Medications for Multiple Sclerosis**

**Immunomodulators**

- Interferons (β-1a, 1b, peginterferon β-1a)
  - Glatiramer acetate
  - Fingolimod
  - Teriflunomide
  - Dimethyl fumarate

**Immunosuppressant**
Mitoxantrone

**Monoclonal antibodies**

- Natalizumab
- Alemtuzumab
- Ocrelizumab

**Potassium channel blockers**

- Dalfampridine (used to improve walking)

---

**Box 59-4**

**Medications to Treat Symptoms of Multiple Sclerosis**

- Bladder and bowel dysfunction: psyllium, docusate
- Fatigue: amantadine, modafinil
- Depression: fluoxetine, sertraline
- Sexual dysfunction: sildenafil, vardenafil
- Neuropathic pain: gabapentin, carbamazepine

---

**Box 59-5**

**Medications to Treat Parkinson’s Disease**

**Medications Affecting the Amount of Dopamine**

- Amantadine
- Apomorphine
- Bromocriptine
- Carbidopa-levodopa
- Pramipexole
- Rasagiline
- Ropinirole
- Rotigotine
- Selegiline hydrochloride
Anticholinergics

- Benztropine mesylate
- Trihexyphenidyl hydrochloride

Catechol-O-Methyltransferase (COMT) Inhibitors

- Carbidopa/levodopa/entacapone
- Entacapone
- Tolcapone

Client Education: Antiseizure Medications

- Take the prescribed medication in the prescribed dose and frequency.
- Take with food to decrease gastrointestinal irritation, but avoid milk and antacids, which impair absorption.
- If taking liquid medication, shake well before ingesting.
- Do not discontinue the medications.
- Avoid alcohol.
- Avoid over-the-counter medications.
- Wear a MedicAlert bracelet.
- Use caution when performing activities that require alertness.
- Maintain good oral hygiene and use a soft toothbrush.
- Maintain preventive dental checkups.
- Maintain follow-up health care visits with periodic blood studies related to determining toxicity.
- Monitor serum glucose levels (diabetes mellitus).
- Urine may be a harmless pink-red or red-brown color.
- Report symptoms of sore throat, bruising, and nosebleeds, which may indicate a blood dyscrasia.
Inform the primary health care provider if side and adverse effects occur, such as bleeding gums, nausea, vomiting, blurred vision, slurred speech, rash, or dizziness.

**Box 59-7**

**Other Antiseizure Medications**

- Carbamazepine
- Gabapentin
- Lacosamide
- Lamotrigine
- Levetiracetam
- Oxcarbazepine
- Pregabalin
- Tiagabine
- Topiramate
- Zonisamide
- Vigabatrin

**Box 59-8**

**Amphetamines**

- Amphetamine sulfate
- Amphetamine/dextroamphetamine
- Atomoxetine
- Dextroamphetamine sulfate
- Dexmethylphenidate
- Lisdexamfetamine
- Methylphenidate hydrochloride

**Box 59-9**

**Anorexiants**

- Benzphetamine hydrochloride
- Bupropion/naltrexone
- Diethylpropion
- Lorcaserin

2085
Box 59-10
Nonopioid Analgesics

**Acetaminophen**
- Acetaminophen

**Aspirin**
- Aspirin (acetylsalicylic acid; ASA)
- Aspirin (acetylsalicylic acid), buffered

**Nonsteroidal Antiinflammatory Drugs**
- Ibuprofen
- Naproxen

**Cyclooxygenase-2 (COX-2) Inhibitor**
- Celecoxib

**Other Nonsteroidal Antiinflammatory Drugs**
- Diclofenac
- Diflunisal
- Etodolac
- Indomethacin
- Ketoprofen
- Ketorolac
- Meclofenamate
- Mefenamic acid
- Meloxicam
- Nabumetone
- Piroxicam
- Sulindac
- Tolmetin
Box 59-11

Side and Adverse Effects of Acetylsalicylic Acid and Nonsteroidal Antiinflammatory Drugs

Acetylsalicylic acid

- Allergic reactions (anaphylaxis, laryngeal edema)
- Bleeding (anemia, hemolysis, increased bleeding time)
- Dizziness
- Drowsiness
- Flushing
- Gastrointestinal symptoms (distress, heartburn, nausea, vomiting)
- Headaches
- Decreased renal function
- Tinnitus
- Visual changes

Nonsteroidal Antiinflammatory Drugs

- Dysrhythmias
- Blood dyscrasias
- Cardiovascular thrombotic events
- Dizziness
- Gastric irritation
- Hepatotoxicity
- Hypotension
- Pruritus
- Decreased renal function
- Sodium and water retention
- Tinnitus

Box 59-12

Opioid Analgesics

- Acetaminophen; hydrocodone*
- Buprenorphine
- Butorphanol tartrate
- Codeine
- Fentanyl
• Hydrocodone
• Hydromorphone
• Levorphanol
• Meperidine
• Methadone
• Morphine
• Nalbuphine
• Oxycodone
• Oxycodone; acetaminophen
• Oxymorphone
• Pentazocine
• Remifentanil
• Sufentanil
• Tapentadol
• Tramadol

* Combinations of opioids with acetaminophen or nonsteroidal antiinflammatory drug analgesics may be used.

**Box 59-13**

**Opioid Antagonists**

• Alvimopan
• Methylnaltrexone
• Naldemedine
• Naloxone
• Naltrexone
• Naloxegol

**Practice Questions**

724. Carbidopa-levodopa is prescribed for a client with Parkinson’s disease. The nurse monitors the client for side and adverse effects of the medication. Which finding indicates that the client is experiencing an adverse effect?

1. Pruritus
2. Tachycardia
3. Hypertension
4. Impaired voluntary movements

725. The home health nurse visits a client who is taking phenytoin for control of
seizures. During the assessment, the nurse notes that the client is taking birth control pills. Which information should the nurse include in the teaching plan?

1. Pregnancy must be avoided while taking phenytoin.
2. The client may stop the medication if it is causing severe gastrointestinal effects.
3. There is the potential of decreased effectiveness of birth control pills while taking phenytoin.
4. There is the increased risk of thrombophlebitis while taking phenytoin and birth control pills together.

726. The nurse is caring for a client in the emergency department who has been diagnosed with Bell’s palsy. The client has been taking acetaminophen, and acetaminophen overdose is suspected. Which antidote should the nurse prepare for administration if prescribed?

1. Pentostatin
2. Auranofin
3. Fludarabine
4. Acetylcysteine

727. Meperidine has been prescribed for a client to treat pain. Which side and adverse effects should the nurse monitor for? Select all that apply.

1. Diarrhea
2. Tremors
3. Drowsiness
4. Hypotension
5. Urinary frequency
6. Increased respiratory rate

728. A client is taking the prescribed dose of phenytoin to control seizures. Results of a phenytoin blood level study reveal a level of 35 mcg/mL (140 mcmol/L). Which finding would be expected as a result of this laboratory result?

1. Hypotension
2. Tachycardia
3. Slurred speech
4. No abnormal finding

729. The client arrives at the emergency department complaining of back spasms. The client states, “I have been taking 2 to 3 aspirin every 4 hours for the last week, and it hasn’t helped my back.” Since acetylsalicylic acid intoxication is suspected, the nurse should assess the client for which manifestation?

1. Tinnitus
2. Diarrhea
3. Constipation
4. Photosensitivity

730. A client with trigeminal neuralgia is being treated with carbamazepine, 400 mg orally daily. Which value indicates that the client is experiencing an
adverse effect to the medication?
1. Sodium level, 140 mEq/L (140 mmol/L)
2. Uric acid level, 4.0 mg/dL (240 mcmol/L)
3. White blood cell count, 3000 mm$^3$ ($3.0 \times 10^9$/L)
4. Blood urea nitrogen level, 10 mg/dL (3.6 mmol/L)

731. The nurse is caring for a client with chronic back pain. Codeine has been prescribed for the client. Specific to this medication, which intervention should the nurse include in the plan of care while the client is taking this medication?
1. Monitor radial pulse.
3. Monitor apical heart rate.
4. Monitor peripheral pulses.

732. The nurse has given medication instructions to a client receiving phenytoin. Which statement indicates that the client has an adequate understanding of the instructions?
1. “Alcohol is not contraindicated while taking this medication.”
2. “Good oral hygiene is needed, including brushing and flossing.”
3. “The medication dose may be self-adjusted, depending on side effects.”
4. “The morning dose of the medication should be taken before a serum medication level is drawn.”

733. A client with myasthenia gravis has become increasingly weaker. The primary health care provider prepares to identify whether the client is reacting to an overdose of the medication (cholinergic crisis) or an increasing severity of the disease (myasthenic crisis). An injection of edrophonium is administered. Which finding would indicate that the client is in cholinergic crisis?
1. No change in the condition
2. Complaints of muscle spasms
3. An improvement of the weakness
4. A temporary worsening of the condition

734. A client with trigeminal neuralgia tells the nurse that acetaminophen is taken daily for the relief of generalized discomfort. Which laboratory value would indicate toxicity associated with the medication?
1. Sodium level of 140 mEq/L (140 mmol/L)
2. Platelet count of 400,000 mm$^3$ ($400 \times 10^9$/L)
3. Prothrombin time of 12 seconds (12 seconds)
4. Direct bilirubin level of 2 mg/dL (34 mcmol/L)

**Answers**

724. **Answer:** 4

**Rationale:** Dyskinesia and impaired voluntary movements may occur with high carbidopa-levodopa dosages. Nausea, anorexia, dizziness, orthostatic hypotension,
bradycardia, and akinesia are frequent side effects of the medication.

**Test-Taking Strategy:** Focus on the subject, an adverse effect. Options 2 and 3 are comparable or alike and are cardiac-related options, so these options can be eliminated first. Next, focus on the client’s diagnosis and select the correct option over option 1 because it relates to the neurological system.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Pharmacology: Neurological Medications: Antiparkinsonian

**Health Problem:** Adult Health: Neurological: Parkinson’s disease

**Priority Concepts:** Clinical Judgment; Safety

**Reference:** Lewis et al. (2017), p. 1390.

725. **Answer:** 3

**Rationale:** Phenytoin enhances the rate of estrogen metabolism, which can decrease the effectiveness of some birth control pills. Options 1, 2, and 4 are inappropriate instructions. Pregnancy does not need to be “avoided” while taking phenytoin; however, because phenytoin may cause some risk to the fetus (Pregnancy Category D medication), consultation with the primary health care provider should be done if pregnancy is considered. Telling a client that there is an increased risk of thrombophlebitis is incorrect and inappropriate and could cause anxiety in the client. A client should not be instructed to stop antiseizure medication.

**Test-Taking Strategy:** Focus on the subject, teaching points for the client taking phenytoin. Eliminate option 1 because of the words must be avoided. Use general medication guidelines to eliminate option 2; the client would not be advised to stop a medication. For the remaining options, eliminate option 4, as it will cause anxiety in the client.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Neurological Medications: Anticonvulsants

**Health Problem:** Adult Health: Neurological: Seizure disorder/epilepsy

**Priority Concepts:** Client Education; Safety

726. **Answer:** 4

**Rationale:** The antidote for acetaminophen is acetylcysteine. The normal therapeutic serum level of acetaminophen is 10 to 20 mcg/mL. A toxic level is higher than 50 mcg/mL, and levels higher than 200 mcg/mL 4 hours after ingestion indicates that there is risk for liver damage. Auranofin is a gold preparation that may be used to treat rheumatoid arthritis. Pentostatin and fludarabine are antineoplastic agents.

**Test-Taking Strategy:** Eliminate options 1 and 3 first because they are comparable or alike (antineoplastic agents). Recalling that auranofin is used to treat rheumatoid arthritis will direct you to the correct option.

**Level of Cognitive Ability:** Applying
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Pharmacology: Pain Medications: Nonopioid analgesics  
**Health Problem:** Adult Health: Neurological: Bell’s palsy  
**Priority Concepts:** Clinical Judgment; Safety  

727. **Answer:** 2, 3, 4

**Rationale:** Meperidine is an opioid analgesic. Side and adverse effects include respiratory depression, drowsiness, hypotension, constipation, urinary retention, nausea, vomiting, and tremors. Meperidine is not commonly prescribed but may be used for acute pain and as a preoperative medication.

**Test-Taking Strategy:** Note the subject, side and adverse effects of meperidine. Recalling that this medication is an opioid analgesic and recalling the effects of an opioid analgesic will assist you in identifying the correct options.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Pain Medications: Opioid analgesics  
**Health Problem:** Adult Health: Neurological: Pain  
**Priority Concepts:** Pain; Safety  

728. **Answer:** 3

**Rationale:** The therapeutic phenytoin level is 10 to 20 mcg/mL (40 to 79 mcmol/L). At a level higher than 20 mcg/mL, involuntary movements of the eyeballs (nystagmus) occur. At a level higher than 30 mcg/mL (120 mcmol/L), ataxia and slurred speech occur.

**Test-Taking Strategy:** Focus on the subject, a phenytoin level of 35 mcg/mL. Use knowledge regarding the therapeutic phenytoin level. From this point, you must know the symptoms that would be noted in the client when the phenytoin level is 35 mcg/mL. Remember that ataxia and slurred speech occur with levels higher than 30 mcg/mL.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Neurological Medications: Anticonvulsants  
**Health Problem:** Adult Health: Neurological: Seizure disorder/epilepsy  
**Priority Concepts:** Intracranial Regulation; Safety  

729. **Answer:** 1

**Rationale:** Mild intoxication with acetylsalicylic acid is called *salicylism* and is experienced commonly when the daily dosage is higher than 4 g. Tinnitus (ringing
in the ears) is the most frequent effect noted with intoxication. Hyperventilation may occur, because salicylate stimulates the respiratory center. Fever may result, because salicylate interferes with the metabolic pathways coupling oxygen consumption and heat production. Options 2, 3, and 4 are not associated specifically with toxicity.

Test-Taking Strategy: Focus on the subject, acetylsalicylic acid intoxication. Options 2 and 3 relate to gastrointestinal symptoms, are comparable or alike, and are eliminated first. From the remaining options, you must know that tinnitus occurs.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Pharmacology: Pain Medications: Nonopioid analgesics
Health Problem: Adult Health: Neurological: Pain
Priority Concepts: Clinical Judgment; Safety

730. Answer: 3

Rationale: Carbamazepine, classified as an antiseizure medication, is used to treat nerve pain. Adverse effects of carbamazepine appear as blood dyscrasias, including aplastic anemia, agranulocytosis, thrombocytopenia, and leukopenia; cardiovascular disturbances, including thrombophlebitis and dysrhythmias; and dermatological effects. The low white blood cell count reflects agranulocytosis. The laboratory values in options 1, 2, and 4 are normal values.

Test-Taking Strategy: Focus on the subject, an adverse effect of carbamazepine. If you are familiar with normal laboratory values, you will note that the only option that indicates an abnormal value is the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Analysis
Content Area: Pharmacology: Neurological Medications: Antiseizure
Health Problem: Adult Health: Neurological: Pain
Priority Concepts: Clinical Judgment; Cellular Regulation

731. Answer: 2

Rationale: While the client is taking codeine, the nurse would monitor vital signs and assess for hypotension. The nurse also should increase fluid intake, palpate the bladder for urinary retention, auscultate bowel sounds, and monitor the pattern of daily bowel activity and stool consistency, because the medication causes constipation. The nurse should monitor respiratory status and initiate deep breathing and coughing exercises. In addition, the nurse monitors the effectiveness of the pain medication.

Test-Taking Strategy: Focus on the subject, a specific nursing consideration related to codeine. Eliminate options 1, 3, and 4 because they are comparable or alike. In addition, relate codeine with constipation.
**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Pharmacology: Neurological Medications: Opioid analgesics  
**Health Problem:** Adult Health: Neurological: Pain  
**Priority Concepts:** Clinical Judgment; Pain  

732. **Answer:** 2

**Rationale:** Typical antiseizure medication instructions include taking the prescribed daily dosage to keep the blood level of the medication constant and having a sample drawn for serum medication level determination before taking the morning dose. The client is taught not to stop the medication abruptly, to avoid alcohol, to check with a primary health care provider before taking over-the-counter medications, to avoid activities in which alertness and coordination are required until medication effects are known, to provide good oral hygiene, and to obtain regular dental care. The client should also wear a MedicAlert bracelet.

**Test-Taking Strategy:** Focus on the subject, an understanding of medication instructions for phenytoin. Using knowledge of general principles related to medication administration will assist you in eliminating options 1 and 3. From the remaining options, recall that medications generally are not taken just before determining therapeutic serum levels, because the results would be artificially high. This leaves oral hygiene as the correct option because of the risk of gingival hyperplasia.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Pharmacology: Neurological Medications: Anticonvulsants  
**Health Problem:** Adult Health: Neurological Medications: Seizure disorder/epilepsy  
**Priority Concepts:** Client Education; Safety  

733. **Answer:** 4

**Rationale:** An edrophonium injection makes the client in cholinergic crisis temporarily worse. An improvement in the weakness indicates myasthenia crisis. Muscle spasms are not associated with this test.

**Test-Taking Strategy:** Focus on the subject, results of an edrophonium test. Recalling that a cholinergic crisis indicates an overdose of medication, it seems reasonable that a worsening of the condition will occur when additional medication is administered.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Analysis  
**Content Area:** Adult Health: Neurological
**Health Problem:** Adult Health: Neurological: Myasthenia gravis  
**Priority Concepts:** Clinical Judgment; Mobility  

734. **Answer:** 4

**Rationale:** In adults, overdose of acetaminophen causes liver damage. The correct option is an indicator of liver function and is the only option that indicates an abnormal laboratory value. The normal direct bilirubin level is 0.1 to 0.3 mg/dL (1.7 to 5.1 mcmol/L). The normal sodium level is 135 to 145 mEq/L (135 to 145 mmol/L). The normal prothrombin time is 11 to 12.5 seconds (11 to 12.5 seconds). The normal platelet count is 150,000 to 400,000 mm$^3$ (150 to 400 × 10$^9$/L).

**Test-Taking Strategy:** Focus on the **subject**, acetaminophen toxicity. Knowledge that acetaminophen causes liver damage and knowledge of normal laboratory results will assist you in answering this question. The correct option is the only abnormal value. Also, of all the options, the bilirubin level is the laboratory value most directly related to liver function.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Analysis  
**Content Area:** Pharmacology: Pain Medications: Nonopioid analgesics  
**Health Problem:** Adult Health: Neurological: Trigeminal neuralgia  
**Priority Concepts:** Clinical Judgment; Cellular Regulation  
UNIT XVI
Musculoskeletal Problems of the Adult Client
Introduction

Pyramid to Success

The Pyramid to Success focuses on the emergency care for a client who sustains a fracture or other musculoskeletal injury, monitoring for complications, and carrying out interventions if complications occur. Nursing care related to casts and traction is emphasized. Skill related to instructing the client in the use of an assistive device such as a cane, walker, or crutches is a Pyramid Point. Pyramid Points also include postoperative care following hip surgery or amputation and care of the client with rheumatoid arthritis or osteoporosis. Focus on the points related to the psychosocial effects as a result of the musculoskeletal disorder, such as unexpected body image changes, and the appropriate and available support services needed for the client.

Client Needs: Learning Objectives

Safe and Effective Care Environment

- Communicating with the interprofessional health care team
- Ensuring that informed consent is obtained for treatments and procedures
- Establishing priorities
- Handling hazardous and infectious materials safely
- Maintaining asepsis related to wounds
- Maintaining confidentiality
- Maintaining standard and other precautions
- Preventing accidents and injuries
- Providing physical therapy and occupational therapy referrals
- Upholding client rights

Health Promotion and Maintenance

- Performing physical assessment related to the musculoskeletal system
- Preventing diseases that occur as a result of the aging process
- Promoting health related to diet and activity
- Providing home care instructions regarding care related to a musculoskeletal disorder
- Reinforcing the importance of prescribed therapy

Psychosocial Integrity
Assessing available support systems and use of community resources
Assessing the client’s ability to cope with mobility limitations and restrictions, feelings of isolation, and loss of independence
Considering cultural, religious, and spiritual influences
Discussing situational role changes as a result of the musculoskeletal disorder
Discussing unexpected body image changes as a result of injury or disease
Identifying sensory and perceptual alterations
Mobilizing coping mechanisms

**Physiological Integrity**

Identifying complications of procedures, injuries, or a fracture
Providing care following diagnostic testing and procedures and surgical interventions
Providing care related to casts and traction
Promoting normal elimination patterns
Promoting self-care measures
Providing emergency care for a fracture or other injury
Providing emergency care if complications following injuries or surgical interventions arise
Providing measures to promote comfort
Teaching about the use of assistive devices for mobility such as canes, walkers, and crutches
Teaching pharmacological therapy
I. Anatomy and Physiology
   A. Skeleton
      1. Axial portion
         a. Cranium
         b. Vertebrae
         c. Ribs
      2. Appendicular portion
         a. Limbs
         b. Shoulders
         c. Hips
   B. Types of bones: Long, short, flat, irregular
      1. Spongy bone
         a. Spongy bone is located in the ends of long bones and the center of flat and irregular bones.
         b. Spongy bone can withstand forces applied in many directions.
      2. Dense (compact) bone
         a. Dense bone covers spongy bone.
         b. Forms a cylinder around a central marrow cavity
         c. Better able to withstand longitudinal forces than horizontal forces
      3. Characteristics of bones
         a. Support and protect structures of the body
         b. Provide attachments for muscles, tendons, and ligaments
         c. Contain tissue in the central cavities, which aids in the formation of blood cells
         d. Assist in regulating calcium and phosphate concentrations
      4. Bone growth
a. The length of bone growth results from ossification of the epiphyseal cartilage at the ends of bones; bone growth stops between the ages of 18 and 25 years.

b. The width of bone growth results from the activity of osteoblasts; it occurs throughout life but slows down with aging.

As aging occurs, bone resorption accelerates, decreasing bone mass and predisposing the client to injury.

C. Types of joints (Table 60-1)

1. Characteristics of joints
   a. Allow movement between bones
   b. Formed where 2 bones join
   c. Surfaces are covered with cartilage.
   d. Enclosed in a capsule (synovial joints)
   e. Contain a cavity filled with synovial fluid (synovial joints)
   f. Ligaments hold the bone and joint in the correct position.
   g. Articulation is the meeting point of 2 or more bones.

2. Synovial fluid
   a. Found in the synovial joint capsule
   b. Formed by the synovial membrane, which lines the joint capsule
   c. Lubricates the cartilage
   d. Provides a cushion against shocks

D. Muscles

1. Characteristics of muscles
   a. Made up of bundles of muscle fibers
   b. Provide the force to move bones
   c. Assist in maintaining posture
   d. Assist with heat production

2. Process of contraction and relaxation
   a. Muscle contraction and relaxation require large amounts of adenosine triphosphate.
   b. Contraction also requires calcium, which functions as a catalyst.
   c. Acetylcholine released by the motor end plate of the motor neuron initiates an action potential.
   d. Acetylcholine is then destroyed by
acetylcholinesterase.
e. Calcium is required for muscle fiber contraction and acts as a catalyst for the enzyme needed for the sliding-together action of actin and myosin.
f. Following contraction, adenosine triphosphate transports calcium out to allow actin and myosin to separate and allow the muscle to relax.

3. Skeletal muscles
   a. Skeletal muscles are attached to 2 bones by cartilaginous tendons called enthuses (the connective tissue between tendon or ligament and bone).
b. The point of origin is the point of attachment that does not move.
c. The point of insertion is the point of attachment that moves when the muscle contracts.
d. Skeletal muscles act in groups.
e. Prime movers contract to produce movement.
f. Antagonists relax.
g. Synergists contract to stabilize body movement.
h. Nerves activate and control the muscles.

E. Bone healing
   1. Description: Bone union or healing is the process that occurs after the integrity of a bone is interrupted.
   2. Stages (Fig. 60-1)

II. Risk Factors Associated with Musculoskeletal Problems: See Box 60-1 for more information

III. Diagnostic Tests
   A. Radiography and magnetic resonance imaging (MRI) (refer to Chapter 58 for information on MRI)
      1. Description: Radiography and MRI are commonly used procedures to diagnose problems of the musculoskeletal system.
   2. Interventions
      a. Handle injured areas carefully and support extremities above and below the joint.
      b. Administer analgesics as prescribed before the procedure, particularly if
the client is in pain.
c. Remove any radiopaque and metallic objects, such as jewelry.
d. Ask the client if she is pregnant; MRI may be contraindicated in pregnancy.
e. Shield the client’s testes, ovaries, or pregnant abdomen.
f. The client must lie still during a procedure.
g. Inform the client that exposure to radiation from radiography is minimal and not dangerous.
h. The health care provider wears a lead apron if staying in the room with the client having radiography.
i. Complete the screening process per agency policy.

B. Arthrocentesis

1. Description: Arthrocentesis is used to diagnose joint inflammation and infection.
   a. Arthrocentesis involves aspirating synovial fluid, blood, or pus via a needle inserted into a joint cavity.
   b. Medication, such as corticosteroids, may be instilled into the joint if necessary to alleviate inflammation.

2. Interventions
   a. Ensure that informed consent has been obtained.
   b. Apply an elastic compression bandage postprocedure as prescribed.
   c. Use ice to decrease pain and swelling.
   d. Pain may worsen after aspirating fluid from the joint; analgesics may be prescribed.
   e. Pain can continue for up to 2 days after administration of corticosteroids into a joint.
   f. Instruct the client to rest the joint for 8 to 24 hours postprocedure.
   g. Instruct the client to notify the primary health care provider (PHCP) if a fever or swelling of the joint occurs.

C. Arthroscopy

1. Description: Used to diagnose and treat acute and chronic problems of the joint.
   a. Arthroscopy provides an endoscopic
examination of various joints.
b. Articular cartilage abnormalities can be assessed, loose bodies removed, and the cartilage trimmed.
c. A biopsy may be performed during the procedure.

2. Interventions
   a. Instruct the client to fast for 8 to 12 hours before the procedure.
   b. Ensure that informed consent was obtained.
   c. Administer pain medication as prescribed postprocedure.
   d. Assess the neurovascular status of the affected extremity.
   e. An elastic compression bandage should be worn postprocedure for 2 to 4 days as prescribed.
   f. Instruct the client that walking with weight-bearing usually is permitted after sensation returns but to limit activity for 1 to 4 days as prescribed following the procedure.
   g. Instruct the client to elevate the extremity as often as possible for 24 hours following the procedure and to place ice on the site to minimize swelling for 12 to 24 hours postprocedure.
   h. Advise the client to notify the PHCP if fever or increased knee pain occurs or if edema continues for more than 3 days postprocedure.

D. Bone mineral density measurements
   1. Dual-energy x-ray absorptiometry
      a. Dual-energy x-ray absorptiometry measures the bone mass of the spine, wrist and hip bones, and total body.
      b. Radiation exposure is minimal.
      c. It is used to diagnose metabolic bone disease and to monitor changes in bone density with treatment.
      d. Inform the client that the procedure is painless.
e. All metallic objects are removed before the test.

2. Quantitative ultrasound
   a. Quantitative ultrasound evaluates strength, density, and elasticity of various bones, using ultrasound rather than radiation.
   b. Inform the client that the procedure is painless.

E. Bone scan
   1. Description: A bone scan is used to identify, evaluate, and stage bone cancer before and after treatment; it is also used to detect fractures.
      a. Radioisotope is injected intravenously and will collect in areas that indicate abnormal bone metabolism and some fractures, if they exist.
      b. The isotope is excreted in the urine and feces within 48 hours and is not harmful to others.
   2. Interventions
      a. Food and fluids may be withheld before the procedure.
      b. Ensure that informed consent has been obtained.
      c. Remove all jewelry and metal objects.
      d. Following the injection of the radioisotope, the client must drink 32 oz of water (if not contraindicated) to promote renal filtering of the excess isotope.
      e. From 1 to 3 hours after the injection, have the client void to clear excess isotope from the bladder before the scanning procedure is completed.
      f. Inform the client of the need to lie supine during the procedure and that the procedure is not painful.
      g. Monitor the injection site for redness and swelling.
      h. Encourage oral fluid intake following the procedure.

No special precautions are required after a
bone scan, because only a minimal amount of radioactivity exists in the radiisotope used for the procedure.

F. Bone or muscle biopsy
   1. Description: Biopsy may be done during surgery or through aspiration or punch or needle biopsy.
   2. Interventions
      a. Ensure that informed consent was obtained.
      b. Monitor for bleeding, swelling, hematoma, or severe pain.
      c. Elevate the site for 24 hours following the procedure to reduce edema.
      d. Apply ice packs as prescribed following the procedure to prevent the development of a hematoma and to decrease site discomfort.
      e. Monitor for signs of infection following the procedure.
      f. Inform the client that mild to moderate discomfort is normal following the procedure.

G. Electromyography (EMG)
   1. Description: EMG is used to evaluate muscle weakness.
      a. Electromyography measures electrical potential associated with skeletal muscle contractions.
      b. Needles are inserted into the muscle, and recordings of muscular electrical activity are traced on recording paper through an oscilloscope.
   2. Interventions
      a. Ensure that informed consent was obtained.
      b. Instruct the client that the needle insertion is uncomfortable.
      c. Instruct the client not to take any stimulants or sedatives for 24 hours before the procedure.
      d. Inform the client that slight bruising may occur at the needle insertion sites.
      e. Mild analgesics can be used for the pain.

IV. Injuries
   A. Strains
1. Strains are an excessive stretching of a muscle or tendon.
2. Management involves cold and heat applications, exercise with activity limitations, antiinflammatory medications, and muscle relaxants.
3. Surgical repair may be required for a severe strain (ruptured muscle or tendon).

B. Sprains
1. Sprains are an excessive stretching of a ligament, usually caused by a twisting motion, such as in a fall or stepping onto an uneven surface.
2. Sprains are characterized by pain and swelling.
3. Management involves rest, ice, a compression bandage, and elevation (RICE) to reduce swelling, as well as joint support. RICE is considered a first-aid treatment, rather than a cure for soft tissue injuries.
4. Casting may be required for moderate sprains to allow the tear to heal.
5. Surgery may be necessary for severe ligament damage.

C. Rotator cuff injuries
1. The musculotendinous or rotator cuff of the shoulder can sustain a tear, usually as a result of trauma.
2. Injury is characterized by shoulder pain and the inability to maintain abduction of the arm at the shoulder (drop arm test).
3. Management involves nonsteroidal anti-inflammatory drugs (NSAIDs), physical therapy, sling support, and ice–heat applications.
4. Surgery may be required if medical management is unsuccessful or a complete tear is present.

V. Fractures
A. Description: A break in the continuity of the bone caused by trauma, twisting as a result of muscle spasm or indirect loss of leverage, or bone decalcification and disease that result in osteopenia.
B. Types of fractures (Box 60-2)
C. Assessment of a fracture of an extremity
   1. Pain or tenderness over the involved area
   2. Decrease or loss of muscular strength or function
   3. Obvious deformity of the affected area
   4. Crepitation, erythema, edema, or bruising
   5. Muscle spasm and neurovascular impairment
D. Initial care of a fracture of an extremity
1. Immobilize the affected extremity with a cast or splint.
2. Assess the neurovascular status of the extremity.
3. Interventions for a fracture: **Reduction, fixation, traction, cast**

If a compound (open) fracture exists, splint the extremity and cover the wound with a sterile dressing.

E. Reduction restores the bone to proper alignment.
1. Closed reduction is a nonsurgical intervention performed by manual manipulation.
   a. Closed reduction may be performed under local or general anesthesia.
   b. A cast may be applied following reduction.
2. Open reduction involves a surgical intervention; the fracture may be treated with **internal fixation** devices.

F. Fixation
1. Internal fixation follows an open reduction (Fig. 60-2).
   a. Internal fixation involves the application of screws, plates, pins, wires, or intramedullary rods to hold the fragments in alignment.
   b. Internal fixation may involve the removal of damaged bone and replacement with a prosthesis.
   c. Internal fixation provides immediate bone stabilization.
2. **External fixation** is the use of an external frame to stabilize a fracture by attaching skeletal pins through bone fragments to a rigid external support (Fig. 60-3).
   a. External fixation provides more freedom of movement than with traction.
   b. Monitor pin stability and provide pin care to decrease infection risks.
   c. Risk of infection exists with both fixation methods.
   d. External fixation is commonly used when massive tissue trauma is present.

G. Traction (Fig. 60-4)
1. Description
   a. Traction is the exertion of a pulling force applied in 2 directions to reduce and immobilize a fracture.
   b. It provides proper bone alignment and
reduces muscle spasms.

2. Interventions

   a. Maintain proper body alignment.
   b. Ensure that the weights hang freely and do not touch the floor.
   c. Do not remove or lift the weights without a PHCP’s prescription.
   d. Ensure that pulleys are not obstructed and that ropes in the pulleys move freely.
   e. Place knots in the ropes to prevent slipping.
   f. Check the ropes for fraying.

H. Skeletal traction

1. Description

   a. Traction is applied mechanically to the bone with pins, wires, or tongs.
   b. Typical weight for skeletal traction is 25 to 40 lb (11 to 18 kg).

2. Interventions

   a. Monitor color, motion, and sensation of the affected extremity.
   b. Monitor the insertion sites for redness, swelling, drainage, or increased pain.
   c. Provide insertion site care as prescribed.

3. Cervical tongs and a halo fixation device: See Chapter 58 regarding care of the client with these types of devices.

I. Skin traction

1. Description: Skin traction is applied by using elastic bandages or adhesive, foam boot, or sling.
2. Cervical skin traction relieves muscle spasms and compression in the upper extremities and neck (see Fig. 60-4).

   a. Cervical skin traction uses a head halter and chin pad to attach the traction.
   b. Use powder to protect the ears from friction rub.
   c. Position the client with the head of the bed elevated 30 to 40 degrees, and attach the weights to a pulley system over the head of the bed.

3. Buck’s (extension) skin traction is used to alleviate muscle spasms and immobilize a lower limb by
maintaining a straight pull on the limb with the use of weights (see Fig. 60-4).

a. A boot appliance is applied to attach to the traction.

b. The weights are attached to a pulley; allow the weights to hang freely over the edge of bed.

c. Not more than 8 to 10 lb (3.5 to 4.5 kg) of weight should be applied as prescribed.

d. Elevate the foot of the bed to provide the traction.

4. Russell’s skin (sling) traction: See Fig. 60-4 and Chapter 39 regarding this type of traction.

5. Pelvic skin traction is used to relieve low back, hip, or leg pain or to reduce muscle spasm (see Fig. 60-4).

a. Apply the traction belt snugly over the pelvis and iliac crest and attach to the weights.

b. Use measures as prescribed to prevent the client from slipping down in bed.

J. Balanced suspension traction (see Fig. 60-4)

1. Description

a. Balanced suspension traction is used with skin or skeletal traction.

b. Used to approximate fractures of the femur, tibia, or fibula

c. Balanced suspension traction is produced by a counterforce other than the client.

2. Interventions

a. Position the client in a low-Fowler’s position on either the side or the back.

b. Maintain a 20-degree angle from the thigh to the bed.

c. Protect the skin from breakdown.

d. Provide pin care if pins are used with skeletal traction.

e. Clean the pin sites with sterile normal saline and hydrogen peroxide or povidone-iodine as prescribed or per agency policy.

K. Casts

1. Description: Plaster, fiberglass, or air casts are used to immobilize bones and joints into correct alignment
after a fracture or injury.

2. Interventions

a. Keep the cast and extremity elevated.
b. Allow a wet plaster cast 24 to 72 hours to dry (synthetic casts dry in 20 minutes).
c. Handle a wet plaster cast with the palms of the hands (not fingertips) until dry.
d. Turn the extremity every 1 to 2 hours, unless contraindicated, to allow air circulation and promote drying of the cast.
e. A hair dryer can be used on a cool setting to dry a plaster cast (heat cannot be used on a plaster cast, because the cast heats up and burns the skin).
f. Monitor closely for circulatory impairment; prepare for bivalving or cutting the cast if circulatory impairment occurs.
g. Petal the cast or apply moleskin to the edges to protect the client’s skin; maintain smooth edges around the cast to prevent crumbling of the cast material.
h. Monitor for signs of infection such as increased temperature, hot spots on the cast, foul odor, or changes in pain.
i. If an open draining area exists on the affected extremity, the PHCP will make a cutout portion of the cast known as a window, for assessment and wound care purposes.
j. Instruct the client not to stick objects inside the cast.
k. Teach the client to keep the cast clean and dry.
l. Instruct the client in isometric exercises to prevent muscle atrophy.

Monitor a casted extremity for circulatory impairment such as pain, swelling, discoloration, tingling, numbness, coolness, or diminished pulse. Notify the PHCP immediately if circulatory impairment occurs.
compromise occurs.

VI. Complications of Fractures (Box 60-3)

A. Fat embolism (see Priority Nursing Actions)

**Priority Nursing Actions**

**Fat Embolism in a Client Following a Fracture**

1. Notify the primary health care provider (PHCP).
2. Administer oxygen.
3. Administer intravenous (IV) fluids as prescribed.
4. Monitor vital signs and respiratory status.
5. Prepare for intubation and mechanical ventilation if necessary as indicated by arterial blood gas values.
6. Follow up on results of diagnostic tests such as chest x-ray or computed tomography (CT) scan.
7. Document the event, actions taken, and the client’s response.

**Reference**

B. Pulmonary embolism

1. Description: Pulmonary embolism is caused by the movement of foreign particles (blood clot, fat, or air) into the pulmonary circulation.
2. Assessment
   a. Restlessness and apprehension
   b. Sudden onset of dyspnea and chest pain
   c. Cough, hemoptysis, hypoxemia, or crackles
3. Interventions
   a. Notify the PHCP immediately if signs of emboli are present.
   b. Administer oxygen and other prescriptions; intravenous (IV) anticoagulant therapy may be prescribed.

C. Compartment syndrome

1. Description
   a. Tough fascia surrounds muscle groups, forming compartments from which arteries, veins, and nerves enter and exit at opposite ends.
   b. Compartment syndrome occurs when pressure increases within 1 or more compartments, leading to decreased blood flow, tissue ischemia, and
neurovascular impairment. Neurovascular damage may be irreversibly if not treated within 4 to 6 hours after the onset of compartment syndrome.

2. Assessment
   a. Unrelieved or increased pain in the limb
   b. Tissue that is distal to the involved area becomes pale, dusky, or edematous.
   c. Pain with passive movement
   d. Loss of sensation (paresthesia)
   e. Pulselessness (a late sign)

3. Interventions
   a. Notify the PHCP immediately and prepare to assist the PHCP.
   b. Continue to elevate the affected extremity.
   c. If severe, assist the PHCP with fasciotomy to relieve pressure and restore tissue perfusion.
   d. Loosen tight dressings or bivalve restrictive cast as prescribed.

D. Infection and osteomyelitis
   1. Description: Infection and osteomyelitis (inflammatory response in bone tissue) can be caused by the introduction of organisms into bones leading to localized bone infection.
   2. Assessment
      a. Tachycardia and fever (usually above 101° F [38.3° C]).
      b. Erythema and pain in the area surrounding the infection
      c. Leukocytosis and elevated erythrocyte sedimentation rate (ESR)
      d. Confirmed by radiographic assessment, such as plain radiographs, MRI, or bone scan
   3. Interventions
      a. Notify the PHCP.
      b. Prepare to initiate aggressive, long-term IV antibiotic therapy. A central venous access line will likely be required.
      c. Surgery is performed for resistant osteomyelitis with sequestrectomy and/or bone grafts.
      d. For unrelenting infection and osteomyelitis, hyperbaric oxygen
therapy is used (if available) to promote healing.

E. Avascular necrosis
1. Description: Avascular necrosis occurs when a fracture interrupts the blood supply to a section of bone, leading to bone death.
2. Assessment
   a. Pain
   b. Decreased sensation
   c. Confirmed by radiographic assessment, such as plain radiographs, MRI, or bone scan
3. Interventions
   a. Notify the PHCP if pain or numbness occurs.
   b. Prepare the client for removal of necrotic tissue, because it serves as a focus for infection.

VII. Crutch Walking
A. Description
   1. An accurate measurement of the client for crutches is important, because an incorrect measurement could damage the brachial plexus.
   2. The distance between the axillae and the arm pieces on the crutches should be 2 to 3 fingerwidths in the axilla space.
   3. The elbows should be slightly flexed, 20 to 30 degrees, when the client is walking.
   4. When ambulating with the client, stand on the affected side.
   5. Instruct the client never to rest the axillae on the axillary bars.
   6. Instruct the client to look up and outward when ambulating and to place the crutches 6 to 10 inches (25.5 cm) diagonally in front of the foot.
   7. Instruct the client to stop ambulation if numbness or tingling in the hands or arms occurs.

B. Crutch gaits (Table 60-2)

C. Assisting the client with crutches to sit and stand
   1. Place the unaffected leg against the front of the chair.
   2. Move the crutches to the affected side, and grasp the arm of the chair with the hand on the unaffected side.
   3. Flex the knee of the unaffected leg to lower self into the chair while placing the affected leg straight out in front.
4. Reverse the steps to move from a sitting to standing position.

D. Going up and down stairs

1. Up the stairs
   a. The client moves the unaffected leg up first.
   b. The client moves the affected leg and the crutches up.

2. Down the stairs
   a. The client moves the crutches and the affected leg down.
   b. The client moves the unaffected leg down.

VIII. Canes and Walkers

A. Description: Canes and walkers are made of a lightweight material with a rubber tip at the bottom.

B. Interventions

1. Stand at the affected side of the client when ambulating; use of a gait or transfer belt may be necessary.
2. The handle should be at the level of the client’s greater trochanter.
3. The client’s elbow should be flexed at a 15- to 30-degree angle.
4. Instruct the client to hold the cane 4 to 6 inches (10 to 15 cm) to the side of the foot.
5. Instruct the client to hold the cane in the hand on the unaffected side, so that the cane and weaker leg can work together with each step.
6. Instruct the client to move the cane at the same time as the affected leg.
7. Instruct the client to inspect the rubber tips regularly for worn places.

C. Hemicanes or quadripod canes

1. Hemicanes or quadripod canes are used for clients who have the use of only 1 upper extremity.
2. Hemicanes provide more security than a quadripod cane; however, both types provide more security than a single-tipped cane.
3. Position the cane at the client’s unaffected side, with the straight, nonangled side adjacent to the body.
4. Position the cane 6 inches (15 cm) from the unaffected client’s side, with the hand grip level with the greater trochanter.
D. Walker

1. Stand adjacent to the client on the affected side.
2. Instruct the client to put all 4 points of the walker flat on the floor before putting weight on the hand pieces.
3. Instruct the client to move the walker forward, followed by the affected or weaker foot and then the unaffected foot.

Safety is the priority concern when the client uses an assistive device such as a cane, walker, or crutches. Be sure that the client demonstrates correct use of the device.

IX. Fractured Hip

A. Types

1. Intracapsular (femoral head is broken within the joint capsule)
   a. Femoral head and neck receive decreased blood supply and heal slowly.
   b. Skin traction is applied preoperatively to reduce the fracture and decrease muscle spasms.
   c. Treatment includes a total hip replacement or open reduction internal fixation (ORIF) with femoral head replacement.
   d. To prevent hip displacement postoperatively, avoid extreme hip flexion, and check the surgeon’s prescriptions regarding positioning.

2. Extracapsular (fracture is outside the joint capsule)
   a. Fracture can occur at the greater trochanter or can be an intertrochanteric fracture.
   b. Preoperative treatment includes balanced suspension or skin traction to relieve muscle spasms and reduce pain.
   c. Surgical treatment includes ORIF with nail plate, screws, pins, or wires.

B. Postoperative interventions

1. Monitor for signs of delirium and institute safety measures.
2. Maintain leg and hip in proper alignment and prevent internal or external rotation; avoid extreme hip
flexion.
3. Follow the PHCP’s prescriptions regarding turning and repositioning; usually, turning to the unaffected side is allowed; protective devices may be prescribed.
4. Elevate the head of the bed 30 to 45 degrees for meals only.
5. Assist the client to ambulate as prescribed by the PHCP.
6. Avoid weight bearing on the affected leg as prescribed; instruct the client in the use of a walker to avoid weight bearing.
7. Weight bearing is often restricted after ORIF and may not be restricted after total hip arthroplasty (THA); always refer to the PHCP’s prescriptions.
8. Keep the operative leg extended, supported, and elevated (preventing hip flexion) when getting the client out of bed.
9. Avoid hip flexion greater than 90 degrees and avoid low chairs when out of bed.
10. Monitor for wound infection or hemorrhage.
11. Administer antibiotics if prescribed within a specified time frame (antibiotics also may be prescribed in the preoperative period).
12. Neurovascular assessment of affected extremity: Check color, pulses, capillary refill, movement, and sensation.
13. Maintain the compression of the drain if present, to facilitate wound drainage.
14. Monitor and record drainage amount, which decreases consistently.
15. As prescribed, carry out postoperative blood salvage to collect, filter, and reinfuse salvaged blood into the client.
16. Use antiembolism stockings or sequential compression stockings as prescribed; encourage the client to flex and extend the feet to reduce the risk of deep vein thrombosis (DVT).
17. Instruct the client to avoid crossing the legs and activities that require bending over.
18. Physical therapy will be instituted postoperatively with progressive ambulation as prescribed by the PHCP.

X. Total Knee Replacement
A. Description: Total knee replacement is the implantation of a device to substitute for the femoral condyles and tibial joint surfaces.

B. Postoperative interventions
1. Monitor surgical incision for drainage and infection.
2. If prescribed, continuous passive motion (CPM) is started soon after the client is admitted to the postoperative unit.
3. Administer analgesics before CPM to decrease pain.
4. Prepare the client for out-of-bed activities as prescribed; have the client avoid leg dangling.
5. Weight bearing with an assistive device is prescribed as tolerated.
6. Postoperative blood salvage may be prescribed to collect, filter, and reinfuse salvaged blood into the client.
7. Administer antibiotics if prescribed within a specified time frame (antibiotics also may be prescribed in the preoperative period).

XI. Joint Dislocation and Subluxation

A. Dislocation: Injury of the ligaments surrounding a joint, which leads to displacement or separating of the articular surfaces of the joint
B. Subluxation: Incomplete displacement of joint surfaces when forces disrupt the soft tissue that surrounds the joints
C. Assessment
   1. Asymmetry of the contour of affected body parts
   2. Pain, tenderness, dysfunction, and swelling
   3. Complications include neurovascular compromise, avascular necrosis, and open joint injuries.
   4. X-rays are taken to determine joint shifting.
D. Interventions
   1. Focus of treatment includes pain relief, joint support, and joint protection.
   2. Immediate treatment is done to reduce the dislocation and realign the dislocated joint.
   3. Open or closed reduction is done followed with a postprocedural joint immobilization device.
   4. Intravenous conscious sedation, local, or general anesthesia is used during joint manipulation.
   5. Initial activity restriction is followed by gentle range-of-motion activities and a gradual return of activities to normal levels while supporting the affected joint.
   6. A weakened joint is prone to recurrent dislocation and may require extended activity restriction.

XII. Herniation: Intervertebral Disk

A. Description: The nucleus of the disk protrudes into the annulus, causing nerve compression.
B. Cervical disk herniation occurs at the C5 to C6 and C6 to C7 interspaces.
   1. Cervical disk herniation causes pain radiation to shoulders, arms, hands, scapulae, and pectoral
2. Motor and sensory deficits can include paresthesia, numbness, and weakness of the upper extremities.

3. Interventions
   a. Conservative management is used unless the client develops signs of neurological deterioration.
   b. Bed rest is prescribed to decrease pressure, inflammation, and pain.
   c. Immobilize the cervical area with a cervical collar or brace.
   d. Apply heat to reduce muscle spasms and apply ice to reduce inflammation and swelling.
   e. Maintain head and spine alignment.
   f. Instruct the client in the use of analgesics, sedatives, antiinflammatory agents, and corticosteroids as prescribed.
   g. Prepare the client for a corticosteroid injection into the epidural space if prescribed.
   h. Assist and instruct the client in the use of a cervical collar or cervical traction as prescribed.

4. Cervical collar is used for cervical disk herniation.
   a. A cervical collar limits neck movement and holds the head in a neutral or slightly flexed position.
   b. The cervical collar may be worn intermittently or 24 hours daily.
   c. Inspect the skin under the collar for irritation.
   d. When prescribed and after pain decreases, exercises are done to strengthen the muscles.

5. Client education related to cervical disk conditions
   a. Avoid flexing, extending, and rotating the neck.
   b. Avoid the prone position and maintain the neck, spine, and hips in a neutral position while sleeping.
c. Minimize long periods of sitting.
d. Instruct the client regarding medications such as analgesics, sedatives, antiinflammatory agents, and corticosteroids.

C. Lumbar disk herniation most often occurs at the L4 to L5 or L5 to S1 interspace.

1. Herniation produces muscle weakness, sensory deficits, and diminished tendon reflexes.
2. The client experiences pain and muscle spasms in the lower back, with radiation of the pain into 1 hip and down the leg (sciatica).
3. Pain is relieved by bed rest and aggravated by movement, lifting, straining, and coughing.
4. Interventions
   a. Conservative management is indicated unless neurological deterioration or bowel and bladder dysfunction occurs.
   b. Apply heat to decrease muscle spasms and apply ice to decrease inflammation and swelling.
   c. Instruct the client to sleep on the side, with the knees and hips flexed, and place a pillow between the legs.
   d. Apply pelvic traction as prescribed to relieve muscle spasms and decrease pain.
   e. Begin progressive ambulation as inflammation, edema, and pain subside.
5. Client education related to lumbar disk conditions
   a. Instruct the client in the use of prescribed medications such as analgesics, muscle relaxants, antiinflammatory agents, or corticosteroids.
   b. Instruct the client about application techniques for corsets or braces to maintain immobilization and proper spine alignment.
   c. Instruct the client in correct posture while sitting, standing, walking, and working.
   d. Instruct the client in the correct
technique to use when lifting objects such as bending the knees, maintaining a straight back, and avoiding lifting objects above the elbow level.

e. Instruct in a weight control program as prescribed.

f. Instruct the client in an exercise program to strengthen back and abdominal muscles as prescribed.

D. Disk surgery is used when spinal cord compression is suspected or symptoms do not respond to conservative treatment; minimally invasive techniques may be prescribed (Box 60-4).

1. Postoperative interventions: Cervical disk

   a. Monitor for respiratory difficulty from inflammation or hematoma.

   b. Encourage coughing, deep breathing, and early ambulation as prescribed.

   c. Monitor for hoarseness and inability to cough effectively, because this may indicate laryngeal nerve damage.

   d. Use throat sprays or lozenges for sore throat, avoiding anesthetic lozenges that may numb the throat and increase choking risks.

   e. Assess the surgical dressing; monitor the surgical wound for infection, swelling, redness, drainage, or pain; and manage surgical drains accordingly.

   f. Provide a soft diet if the client complains of dysphagia.

   g. Monitor for sudden return of radicular pain, which may indicate cervical spine instability.

2. Postoperative interventions: Lumbar disk

   a. Assess the surgical dressing, monitoring for wound drainage and bleeding and monitoring surgical drains accordingly.

   b. Monitor lower extremities for sensation, movement, color, temperature, and paresthesia.

   c. Monitor for urinary retention, paralytic ileus, and constipation, which can
result from decreased movement, opioid administration, or spinal cord compression.

d. Prevent constipation by encouraging a high-fiber diet, increased fluid intake, and stool softeners as prescribed.
e. Administer opioids and sedatives as prescribed to relieve pain and anxiety.
f. Assist and instruct the client to use a prescribed back brace or corset and to wear cotton underwear to prevent skin irritation.

3. Postoperative lumbar disk positioning
   a. In the immediate postoperative period, the client may be expected to lie supine or have other activity restrictions, depending on the specific surgical intervention.
   b. Instruct the client to avoid spinal flexion or twisting and that the spine should be kept aligned.
   c. Instruct the client to minimize sitting, which may place a strain on the surgical site.
   d. When the client is lying supine, place a pillow under the neck and slightly flex the knees.
   e. Avoid extreme hip flexion when lying on the side.

Following disk surgery, instruct the client in correct logrolling techniques for turning and repositioning and for getting out of bed.

XIII. Amputation of a Lower Extremity
   A. Description
      1. Amputation (Fig. 60-5) is the surgical removal of a limb or part of the limb.
      2. Complications include hemorrhage, infection, phantom limb sensation and pain, neuroma, and flexion contractures.

   B. Postoperative interventions
      1. Monitor for signs of complications.
      2. Mark bleeding and drainage on the dressing if it occurs.
3. Evaluate for phantom limb sensation and pain; explain sensation and pain to the client, and medicate the client as prescribed.
4. To prevent hip flexion contractures, do not elevate the residual limb on a pillow.
5. First 24 hours: Elevate the foot of the bed to reduce edema; then keep the bed flat to prevent hip flexion contractures, if prescribed by the PHCP.
6. After 24 to 48 hours postoperatively, position the client prone to stretch the muscles and prevent hip flexion contractures, if prescribed.
7. Maintain surgical application of dressing, elastic compression wrap, or elastic stump (residual limb) shrinker as prescribed to reduce swelling, minimize pain, and mold the residual limb in preparation for prosthesis (Fig. 60-6)
8. As prescribed, wash the residual limb with mild soap and water and dry completely.
9. Massage the skin toward the suture line if prescribed, to mobilize scar tissue and prevent its adherence to underlying bone.
10. Prepare for the prosthesis and instruct the client in progressive resistive techniques by gently pushing the residual limb against pillows and progressing to firmer surfaces.
11. Encourage verbalization regarding loss of the body part, and assist the client to identify coping mechanisms to deal with the loss.

C. Interventions for below-knee amputation
1. Prevent edema.
2. Do not allow the residual limb to hang over the edge of the bed.
3. Discourage long periods of sitting to lessen complications of knee flexion.
4. Place the client in a prone position throughout the day as prescribed by the PHCP.

D. Interventions for above-knee amputation
1. Prevent internal or external rotation of the limb.
2. Place a sandbag, rolled towel, or trochanter roll along the outside of the thigh to prevent external rotation.
3. Place the client in a prone position throughout the day as prescribed by the PHCP.

E. Rehabilitation
1. Instruct the client in the use of a mobility aid such as crutches or a walker.
2. Prepare the residual limb for a prosthesis.
3. Prepare the client for fitting of the residual limb for a prosthesis.
4. Instruct the client in exercises to maintain range of motion and upper body strengthening.
5. Provide psychosocial support to the client.

F. Traumatic amputation: Emergency care

1. Obtain emergency medical assistance (call 911).
2. Stay with the victim, check the amputation site, and apply direct pressure with gauze or cloth (do not remove applied pressure dressing to prevent dislodging of a formed clot).
3. Elevate the extremity above heart level.
4. If finger(s) were amputated, place them in a watertight, sealed plastic bag; place the bag in ice water (not directly on ice); and transport to the emergency department with the victim.

XIV. Rheumatoid Arthritis

A. Description

1. Rheumatoid arthritis is a chronic systemic inflammatory disease (immune complex disorder); the cause may be related to a combination of environmental and genetic factors.
2. Rheumatoid arthritis leads to destruction of connective tissue and synovial membrane within the joints.
3. Rheumatoid arthritis weakens the joint, leading to dislocation and permanent deformity of the joint.
4. Pannus forms at the junction of synovial tissue and articular cartilage and projects into the joint cavity, causing necrosis.
5. Exacerbations of disease manifestations occur during periods of physical or emotional stress and fatigue.
6. Vasculitis can impede blood flow, leading to organ or organ system malfunction and failure caused by tissue ischemia.

B. Assessment

1. Inflammation, tenderness, and stiffness of the joints
2. Moderate to severe pain, with morning stiffness lasting longer than 30 minutes
3. Joint deformities, muscle atrophy, and decreased range of motion in affected joints
4. Spongy, soft feeling in the joints
5. Low-grade temperature, fatigue, and weakness
6. Anorexia, weight loss, and anemia
7. Elevated ESR and positive rheumatoid factor
8. Radiographic study showing joint deterioration
9. Synovial tissue biopsy reveals inflammation
C. Rheumatoid factor
   1. Blood test used to assist in diagnosing rheumatoid arthritis
   2. Reference interval: Negative or less than 60 IU/mL

D. Medications: Combination of pharmacological therapies includes NSAIDs, disease-modifying antirheumatic drugs (DMARDs), and glucocorticoids

E. Physical mobility
   1. Preserve joint function.
   2. Provide range-of-motion exercises to maintain joint motion and muscle strengthening.
   4. Splints may be used during acute inflammation to prevent deformity.
   5. Prevent flexion contractures.
   6. Apply heat or cold therapy as prescribed to joints.
   7. Apply paraffin baths and massage as prescribed.
   8. Encourage consistency with exercise program.
   10. Avoid weight bearing on inflamed joints.

F. Self-care (Box 60-5)
   1. Assess the need for assistive devices such as raised toilet seats, self-rising chairs, wheelchairs, and scooters to facilitate mobility.
   2. Work with an occupational therapist or PHCP to obtain assistive or adaptive devices.
   3. Instruct the client in alternative strategies for providing activities of daily living.

G. Fatigue
   1. Identify factors that may contribute to fatigue.
   2. Monitor for signs of anemia and administer iron, folic acid, and vitamins as prescribed.
   3. Monitor for medication-related blood loss by testing the stool for occult blood.
   4. Instruct the client in measures to conserve energy, such as pacing activities and obtaining assistance when possible.

H. Disturbed body image
   1. Assess the client’s reaction to the body change.
   2. Encourage the client to verbalize feelings.
   3. Assist the client with self-care activities and grooming.
   4. Encourage the client to get dressed daily and to wear street clothes.

I. Surgical interventions
   1. Synovectomy: Surgical removal of the synovia to help maintain joint function
   2. Arthrodesis: Bony fusion of a joint to regain some mobility
3. Joint replacement (arthroplasty): Surgical replacement of diseased joints with artificial joints; performed to restore motion to a joint and function to the muscles, ligaments, and other soft tissue structures that control a joint

XV. Osteoarthritis (Degenerative Joint Disease)

A. Description
1. Osteoarthritis is marked by progressive deterioration of the articular cartilage.
2. Osteoarthritis causes bone buildup and the loss of articular cartilage in peripheral and axial joints.
3. Osteoarthritis affects the weight-bearing joints and joints that receive the greatest stress, such as the hips, knees, lower vertebral column, and hands.
4. The cause of primary osteoarthritis is not known. Risk factors include trauma, aging, obesity, genetic changes, and smoking.

B. Assessment
1. The client experiences joint pain that diminishes after rest and intensifies after activity, noted early in the disease process.
2. As the disease progresses, pain occurs with slight motion or even at rest.
3. Symptoms are aggravated by temperature change and climate humidity.
4. Presence of Heberden’s nodes or Bouchard’s nodes (hands)
5. Joint swelling (may be minimal), crepitus, and limited range of motion
6. Difficulty getting up after prolonged sitting
7. Skeletal muscle disuse atrophy
8. Inability to perform activities of daily living
9. Compression of the spine as manifested by radiating pain, stiffness, and muscle spasms in 1 or both extremities

C. Pain
1. Administer medications as prescribed, such as acetaminophen or topical applications; if acetaminophen or topical agents do not relieve pain, NSAIDs may be prescribed. Muscle relaxants may also be prescribed for muscle spasms, especially those occurring in the back.
2. Prepare the client for corticosteroid injections into joints as prescribed.
3. Position joints in function position and avoid flexion
of knees and hips.
4. Immobilize the affected joint with a splint or brace until inflammation subsides.
5. Avoid large pillows under the head or knees.
6. Provide a bed or foot cradle to keep linen off of feet and legs until inflammation subsides.
7. Instruct the client in the importance of moist heat, hot packs or compresses, and paraffin dips as prescribed.
8. Apply cold applications as prescribed when the joint is acutely inflamed.
9. Encourage adequate rest.

D. Nutrition
1. Encourage a well-balanced diet.
2. Maintain weight within normal range to decrease stress on the joints.

E. Physical mobility
1. Instruct the client to balance activity with rest and to participate in an exercise program that limits stressing affected joints.
2. Instruct the client that exercises should be active rather than passive and to stop exercise if pain occurs.
3. Instruct the client to limit exercise when joint inflammation is severe.

F. Surgical management
1. Osteotomy: The bone is resected to correct joint deformity, promote realignment, and reduce joint stress.
2. Total joint replacement or arthroplasty
   a. Total joint replacement is performed when all measures of pain relief have failed.
   b. Hips and knees are replaced most commonly.
   c. Total joint replacement is contraindicated in the presence of infection, advanced osteoporosis, or severe joint inflammation.

XVI. Osteoporosis

A. Description
1. Osteoporosis is a metabolic disease characterized by bone demineralization, with loss of calcium and phosphorus salts leading to fragile bones and the subsequent risk for fractures.
2. Bone resorption accelerates as bone formation slows.
3. Osteoporosis occurs most commonly in the wrist, hip, and vertebral column.
4. Osteoporosis can occur postmenopausally or as a
result of a metabolic disorder or calcium deficiency.

5. The client may be asymptomatic until the bones become fragile and a minor injury or movement causes a fracture.

6. Primary osteoporosis
   a. Most often occurs in postmenopausal women; occurs in men with low testosterone levels
   b. Risk factors include decreased calcium intake, deficient estrogen, and sedentary lifestyle.

7. Secondary osteoporosis
   a. Causes include prolonged therapy with corticosteroids, thyroid-reducing medications, aluminum-containing antacids, or antiseizure medications.
   b. Associated with immobility, alcoholism, malnutrition, or malabsorption

B. Assessment
   1. Risk factors (Box 60-6)
   2. Possibly asymptomatic
   3. Back pain that occurs after lifting, bending, or stooping
   4. Back pain that increases with palpation
   5. Pelvic or hip pain, especially with weight bearing
   6. Problems with balance
   7. Decline in height from vertebral compression
   8. Kyphosis of the dorsal spine, also known as “dowager’s hump”
   9. Degeneration of lower thorax and lumbar vertebrae on radiographic studies

The client with osteoporosis is at risk for pathological fractures.

C. Interventions
   1. Assess risk for and prevent injury in the client’s personal environment.
      a. Assist the client to identify and correct hazards in his or her environment.
      b. Position household items and furniture to ensure an unobstructed walkway.
      c. Use side rails to prevent falls.
      d. Instruct in use of assistive devices such as a cane or walker.
      e. Encourage the use of a firm mattress.
2. Provide personal care to the client to reduce injuries.
   a. Move the client gently when turning and repositioning.
   b. Assist with ambulation if the client is unsteady.
   c. Provide gentle range-of-motion exercises.
   d. Apply a back brace as prescribed during an acute phase to immobilize the spine and provide spinal column support.

3. Provide the client with instructions to promote optimal level of health and function.
   a. Instruct the client in the use of correct body mechanics.
   b. Instruct the client in exercises to strengthen abdominal and back muscles to improve posture and provide support for the spine.
   c. Instruct the client to avoid activities that can cause vertebral compression.
   d. Instruct the client to eat a diet high in protein, calcium, vitamins C and D, and iron.
   e. Instruct the client to avoid alcohol and coffee.
   f. Instruct the client to maintain an adequate fluid intake to prevent renal calculi.

4. Administer medications as prescribed to promote bone strength and decrease pain.

XVII. Gout
   A. Description
      1. Gout is a systemic disease in which urate crystals deposit in joints and other body tissues.
      2. Gout results from abnormal amounts of uric acid in the body.
      3. Primary gout results from a disorder of purine metabolism.
      4. Secondary gout involves excessive uric acid in the blood, caused by another disease.
   B. Phases
      1. Asymptomatic: Client has no symptoms, but serum uric acid level is elevated.
      2. Acute: Client has excruciating pain and inflammation of 1 or more small joints, especially the great toe.
      3. Intermittent: Client has intermittent periods without symptoms between acute attacks.
4. Chronic: Results from repeated episodes of acute gout
   a. Results in deposits of urate crystals under the skin
   b. Results in deposits of urate crystals within major organs, such as the kidneys, leading to organ dysfunction

C. Assessment
   1. Swelling and inflammation of the joints, leading to excruciating pain
   2. Tophi: Hard, irregularly shaped nodules in the skin containing chalky deposits of sodium urate
   3. Low-grade fever, malaise, and headache
   4. Pruritus from urate crystals in the skin
   5. Presence of renal stones from elevated uric acid levels

D. Interventions
   1. Provide a low-purine diet as prescribed, avoiding foods such as organ meats, wines, and aged cheese.
   2. Encourage a high fluid intake of 2000 mL/day to prevent stone formation.
   3. Encourage a weight reduction diet if required.
   4. Instruct the client to avoid alcohol and starvation diets, because they may precipitate a gout attack.
   5. Increase urinary pH (above 6) by eating alkaline ash foods (i.e., green beans, broccoli).
   6. Provide bed rest during acute attacks, with the affected extremity elevated.
   7. Monitor joint range-of-motion ability and appearance of joints.
   8. Position the joint in mild flexion during acute attack.
   9. Protect the affected joint from excessive movement or direct contact with sheets or blankets.
   10. Provide heat or cold for local treatments to affected joint as prescribed.
   11. Administer medications such as analgesic, antiinflammatory, and uricosuric agents as prescribed.

**Risk Factors Associated with Musculoskeletal Problems**

- Autoimmune disorders
- Calcium deficiency
- Falls
- Hyperuricemia
- Infection
- Medications
- Metabolic disorders
- Neoplastic disorders
- Obesity
- Postmenopausal states
- Trauma and injury

### Box 60-2
**Types of Fractures**

*Closed or Simple:* Skin over the fractured area remains intact.
*Comminuted:* The bone is splintered or crushed, creating numerous fragments.
*Complete:* The bone is separated completely by a break into 2 parts.
*Compression:* A fractured bone is compressed by other bone.
*Depressed:* Bone fragments are driven inward.
*Greenstick:* One side of the bone is broken and the other is bent; these fractures
occur most commonly in children.

**Impacted:** A part of the fractured bone is driven into another bone.

**Incomplete:** Fracture line does not extend through the full transverse width of the bone.

**Oblique:** The fracture line runs at an angle across the axis of the bone.

**Open or Compound:** The bone is exposed to air through a break in the skin, and soft tissue injury and infection are common.

**Pathological:** The fracture results from weakening of the bone structure by pathological processes such as neoplasia; also called *spontaneous fracture*.

**Spiral:** The break partially encircles bone.

**Transverse:** The bone is fractured straight across.

**Box 60-4**

**Types of Disk Surgery**

- **Diskectomy**: Removal of herniated disk tissue and related matter
- **Diskectomy with Fusion**: Fusion of vertebrae with bone graft
- **Laminectomy**: Excision of part of the vertebrae (lamina) to remove the disk
- **Laminotomy**: Division of the lamina of a vertebra
FIG. 60-5  Common levels of lower extremity amputation.

Box 60-5
Client Education for Rheumatoid Arthritis and Degenerative Joint Disease

▪ Assist the client to identify and correct safety hazards in the home.
▪ Instruct the client in the correct use of assistive or adaptive devices.
▪ Instruct the client in energy conservation measures.
▪ Review the prescribed exercise program.
▪ Instruct the client to sit in a chair with a high, straight back.
▪ Instruct the client to use only a small pillow when lying down.
▪ Instruct the client in measures to protect the joints.
▪ Instruct the client regarding the prescribed medications.
▪ Stress the importance of follow-up visits with the primary health care provider.

Box 60-6
Risk Factors for Osteoporosis

▪ Cigarette smoking
▪ Early menopause
▪ Excessive use of alcohol
▪ Family history
▪ Female gender
▪ Increasing age
▪ Insufficient intake of calcium
▪ Sedentary lifestyle
▪ Thin, small frame
▪ White (European descent) or Asian race

Practice Questions

735. The nurse is conducting health screening for osteoporosis. Which client is at greatest risk of developing this problem?
   1. A 25-year-old woman who runs
   2. A 36-year-old man who has asthma
   3. A 70-year-old man who consumes excess alcohol
   4. A sedentary 65-year-old woman who smokes cigarettes

736. The nurse has given instructions to a client returning home after knee arthroscopy. Which statement by the client indicates that the instructions are understood?
   1. “I can resume regular exercise tomorrow.”
2. “I can’t eat food for the remainder of the day.”
3. “I need to stay off the leg entirely for the rest of the day.”
4. “I need to report a fever or swelling to my health care provider.”

737. The nurse witnessed a vehicle hit a pedestrian. The victim is dazed and tries to get up. A leg appears fractured. Which intervention should the nurse take?
   1. Try to reduce the fracture manually.
   2. Assist the victim to get up and walk to the sidewalk.
   3. Leave the victim for a few moments to call an ambulance.
   4. Stay with the victim and encourage him or her to remain still.

738. Which cast care instructions should the nurse provide to a client who just had a plaster cast applied to the right forearm? **Select all that apply.**
   1. Keep the cast clean and dry.
   2. Allow the cast 24 to 72 hours to dry.
   3. Keep the cast and extremity elevated.
   4. Expect tingling and numbness in the extremity.
   5. Use a hair dryer set on a warm to hot setting to dry the cast.
   6. Use a soft, padded object that will fit under the cast to scratch the skin under the cast.

739. The nurse is evaluating a client in skeletal traction. When evaluating the pin sites, the nurse would be **most** concerned with which finding?
   1. Redness around the pin sites
   2. Pain on palpation at the pin sites
   3. Thick, yellow drainage from the pin sites
   4. Clear, watery drainage from the pin sites

740. The nurse is assessing the casted extremity of a client. Which sign is indicative of infection?
   1. Dependent edema
   2. Diminished distal pulse
   3. Presence of a “hot spot” on the cast
   4. Coolness and pallor of the extremity

741. A client has sustained a closed fracture and has just had a cast applied to the affected arm. The client is complaining of intense pain. The nurse elevates the limb, applies an ice bag, and administers an analgesic, with little relief. Which problem may be causing this pain?
   1. Infection under the cast
   2. The anxiety of the client
   3. Impaired tissue perfusion
   4. The recent occurrence of the fracture

742. The nurse is admitting a client with multiple trauma injuries to the nursing unit. The client has a leg fracture and had a plaster cast applied. Which position would be **best** for the casted leg?
   1. Elevated for 3 hours, then flat for 1 hour
   2. Flat for 3 hours, then elevated for 1 hour
   3. Flat for 12 hours, then elevated for 12 hours
4. Elevated on pillows continuously for 24 to 48 hours

743. A client is being discharged to home after application of a plaster leg cast. Which statement indicates that the client understands proper care of the cast?

1. “I need to avoid getting the cast wet.”
2. “I need to cover the casted leg with warm blankets.”
3. “I need to use my fingertips to lift and move my leg.”
4. “I need to use something like a padded coat hanger end to scratch under the cast if it itches.”

744. A client being measured for crutches asks the nurse why the crutches cannot rest up underneath the arm for extra support. The nurse responds knowing that which would most likely result from this improper crutch measurement?

1. A fall and further injury
2. Injury to the brachial plexus nerves
3. Skin breakdown in the area of the axilla
4. Impaired range of motion while the client ambulates

745. The nurse has given the client instructions about crutch safety. Which statements indicate that the client understands the instructions? Select all that apply.

- 1. “I should not use someone else’s crutches.”
- 2. “I need to remove any scatter rugs at home.”
- 3. “I can use crutch tips even when they are wet.”
- 4. “I need to have spare crutches and tips available.”
- 5. “When I’m using the crutches, my arms need to be completely straight.”

746. The nurse is caring for a client being treated for fat embolus after multiple fractures. Which data would the nurse evaluate as the most favorable indication of resolution of the fat embolus?

1. Clear mentation
2. Minimal dyspnea
3. Oxygen saturation of 85%
4. Arterial oxygen level of 78 mm Hg

747. The nurse has conducted teaching with a client in an arm cast about the signs and symptoms of compartment syndrome. The nurse determines that the client understands the information if the client states that he or she should report which early symptom of compartment syndrome?

1. Cold, bluish-colored fingers
2. Numbness and tingling in the fingers
3. Pain that increases when the arm is dependent
4. Pain that is out of proportion to the severity of the fracture

748. A client with diabetes mellitus has had a right below-knee amputation. Given the client’s history of diabetes mellitus, which complication is the client at most risk for after surgery?

1. Hemorrhage
2. Edema of the residual limb
3. Slight redness of the incision
4. Separation of the wound edges

749. The nurse is caring for a client who had an above-knee amputation 2 days ago. The residual limb was wrapped with an elastic compression bandage, which has come off. Which **immediate** action should the nurse take?
   1. Apply ice to the site.
   2. Call the primary health care provider (PHCP).
   3. Rewrap the residual limb with an elastic compression bandage.
   4. Apply a dry, sterile dressing and elevate the residual limb on 1 pillow.

750. A client is complaining of low back pain that radiates down the left posterior thigh. The nurse should ask the client if the pain is worsened or aggravated by which factor?
   1. Bed rest
   2. Ibuprofen
   3. Bending or lifting
   4. Application of heat

751. The nurse is caring for a client who has had spinal fusion, with insertion of hardware. The nurse would be **most** concerned with which assessment finding?
   1. Temperature of 101.6° F (38.7° C) orally
   2. Complaints of discomfort during repositioning
   3. Old bloody drainage outlined on the surgical dressing
   4. Discomfort during coughing and deep-breathing exercises

752. The nurse is caring for a client with a diagnosis of gout. Which laboratory value would the nurse expect to note in the client?
   1. Calcium level of 9.0 mg/dL (2.25 mmol/L)
   2. Uric acid level of 9.0 mg/dL (540 mcmol/L)
   3. Potassium level of 4.1 mEq/L (4.1 mmol/L)
   4. Phosphorus level of 3.1 mg/dL (1.0 mmol/L)

753. A client with a hip fracture asks the nurse about Buck’s (extension) traction that is being applied before surgery and what is involved. The nurse should provide which information to the client?
   1. Allows bony healing to begin before surgery and involves pins and screws
   2. Provides rigid immobilization of the fracture site and involves pulleys and wheels
   3. Lengthens the fractured leg to prevent severing of blood vessels and involves pins and screws
   4. Provides comfort by reducing muscle spasms, provides fracture immobilization, and involves pulleys and wheels

**Answers**

735. **Answer:** 4
**Rationale:** Risk factors for osteoporosis include female gender, being postmenopausal, advanced age, a low-calcium diet, excessive alcohol intake, being sedentary, and smoking cigarettes. Long-term use of corticosteroids, anticonvulsants, and/or furosemide also increases the risk.

**Test-Taking Strategy:** Focus on the subject, risk factors for osteoporosis. The 25-year-old woman who runs (exercises using the long bones) has negligible risk. The 36-year-old man with asthma is eliminated next because his only risk factor might be long-term corticosteroid use (if prescribed) to treat the asthma. Of the remaining options, the 65-year-old woman has higher risk (age, gender, postmenopausal, sedentary, smoking) than the 70-year-old man (age, alcohol consumption).

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Health Promotion and Maintenance

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Musculoskeletal

**Health Problem:** Adult Health: Musculoskeletal: Osteoporosis

**Priority Concepts:** Health Promotion; Mobility

736. Answer: 4

**Rationale:** After arthroscopy, the client usually can walk carefully on the leg once sensation has returned. The client is instructed to avoid strenuous exercise for the length of time prescribed by the surgeon. The client may resume the usual diet. Signs and symptoms of infection should be reported to the primary health care provider.

**Test-Taking Strategy:** Focus on the subject, teaching points following knee arthroscopy. Recalling the general client teaching points related to surgical procedures and that a risk for infection exists after a surgical procedure will direct you to the correct option.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Evaluation

**Content Area:** Adult Health: Musculoskeletal

**Health Problem:** N/A

**Priority Concepts:** Client Education; Safety

737. Answer: 4

**Rationale:** With a suspected fracture, the victim is not moved unless it is dangerous to remain in that spot. The nurse should remain with the victim and have someone else call for emergency help. A fracture is not reduced at the scene. Before the victim is moved, the site of fracture is immobilized to prevent further injury.

**Test-Taking Strategy:** Eliminate options 1 and 2 first because they are comparable or alike in that either of these options could result in further injury to the victim. Of the remaining options, the more prudent action would be for the nurse to remain with the victim and have someone else call for emergency assistance.

**Level of Cognitive Ability:** Applying
Rationale: A plaster cast takes 24 to 72 hours to dry (synthetic casts dry in 20 minutes). The cast and extremity should be elevated to reduce edema if prescribed. A wet cast is handled with the palms of the hand until it is dry, and the extremity is turned (unless contraindicated) so that all sides of the wet cast will dry. A cool setting on the hair dryer can be used to dry a plaster cast (heat cannot be used on a plaster cast because the cast heats up and burns the skin). The cast needs to be kept clean and dry, and the client is instructed not to stick anything under the cast because of the risk of breaking skin integrity. The client is instructed to monitor the extremity for circulatory impairment, such as pain, swelling, discoloration, tingling, numbness, coolness, or diminished pulse. The primary health care provider is notified immediately if circulatory impairment occurs.

Test-Taking Strategy: Focus on the subject, a plaster cast. Recalling that edema occurs following a fracture and recalling the complications associated with a cast will assist you in answering the question.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Adult Health: Musculoskeletal
Health Problem: Adult Health: Musculoskeletal: Skeletal Injury
Priority Concepts: Client Education; Safety

739. Answer: 3

Rationale: The nurse should monitor for signs of infection such as inflammation, purulent (thick white or yellow) drainage, and pain at the pin site. However, some degree of inflammation, pain at the pin site, and serous drainage would be expected; the nurse should correlate assessment findings with other clinical findings, such as fever, elevated white blood cell count, and changes in vital signs. Additionally, the nurse should compare any findings to baseline findings to determine if there were any changes.

Test-Taking Strategy: Note the strategic word, most. Determine if an abnormality exists. Recall that purulent drainage is indicative of infection, and that some degree of pain, inflammation, and serous drainage should be expected.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Adult Health: Musculoskeletal
Health Problem: Adult Health: Musculoskeletal: Skeletal Injury
Priority Concepts: Clinical Judgment; Tissue Integrity

740. Answer: 3

Rationale: Signs of infection under a casted area include odor or purulent drainage from the cast or the presence of “hot spots,” which are areas of the cast that are warmer than others. The primary health care provider should be notified if any of these occur. Signs of impaired circulation in the distal limb include coolness and pallor of the skin, diminished distal pulse, and edema.

Test-Taking Strategy: Focus on the subject, signs of infection. Think about what you would expect to note with infection—redness, swelling, heat, and purulent drainage. With this in mind, you can eliminate options 2 and 4 easily. From the remaining options, remember that “dependent edema” is not necessarily indicative of infection. Swelling would be continuous. The hot spot on the cast could signify infection underneath that area.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Musculoskeletal
Health Problem: Adult Health: Musculoskeletal: Skeletal Injury
Priority Concepts: Infection; Tissue Integrity

741. Answer: 3

Rationale: Most pain associated with fractures can be minimized with rest, elevation, application of cold, and administration of analgesics. Pain that is not relieved by these measures should be reported to the primary health care provider because pain unrelieved by medications and other measures may indicate neurovascular compromise. Because this is a new closed fracture and cast, infection would not have had time to set in. Intense pain after casting is normally not associated with anxiety or the recent occurrence of the injury. Treatment following the fracture should assist in relieving the pain associated with the injury.

Test-Taking Strategy: Focus on the subject, intense pain, and focus on the data in the question. Use of the ABCs—airway, breathing, and circulation—will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Musculoskeletal
Health Problem: Adult Health: Musculoskeletal: Skeletal Injury
Priority Concepts: Pain; Tissue Integrity

742. Answer: 4
**Rationale:** A casted extremity is elevated continuously for the first 24 to 48 hours to minimize swelling and promote venous drainage. Options 1, 2, and 3 are incorrect.

**Test-Taking Strategy:** Note the strategic word, best. Recalling that edema is a concern following an injury and knowledge of the effects of gravity on edema will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Adult Health: Musculoskeletal

**Health Problem:** Adult Health: Musculoskeletal: Skeletal Injury

**Priority Concepts:** Perfusion; Tissue Integrity

743. Answer: 1

**Rationale:** A plaster cast must remain dry to keep its strength. The cast should be handled with the palms of the hands, not the fingertips, until fully dry; using the fingertips results in indentations in the cast and skin pressure under the cast. Air should circulate freely around the cast to help it dry; the cast also gives off heat as it dries. The client should never scratch under the cast because of the risk of altered skin integrity; the client may use a hair dryer on the cool setting to relieve an itch.

**Test-Taking Strategy:** Focus on the subject, client understanding about cast care. Knowing that a wet cast can be dented with the fingertips, causing pressure underneath, helps eliminate option 3 first. Knowing that the cast needs to dry helps eliminate option 2 next. Option 4 is dangerous to skin integrity and is also eliminated. Remember that plaster casts, once they have dried after application, should not become wet.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Evaluation

**Content Area:** Adult Health: Musculoskeletal

**Health Problem:** Adult Health: Musculoskeletal: Skeletal Injury

**Priority Concepts:** Client Education; Safety

744. Answer: 2

**Rationale:** Crutches are measured so that the tops are 2 to 3 fingerwidths from the axillae. This ensures that the client’s axillae are not resting on the crutch or bearing the weight of the crutch, which could result in injury to the nerves of the brachial plexus. Although the conditions in options 1, 3, and 4 can occur, they are not the most likely result from resting the axilla directly on the crutches.

**Test-Taking Strategy:** Note the strategic words, most likely, and focus on the data in the question. Recalling the risk associated with brachial nerve plexus injury will direct you to the correct option.

**Level of Cognitive Ability:** Applying
Client Needs: Physiological Integrity  
Integrated Process: Teaching and Learning  
Content Area: Adult Health: Musculoskeletal  
Health Problem: Adult Health: Musculoskeletal: Skeletal Injury  
Priority Concepts: Client Education; Safety  

745. Answer: 1, 2, 4

Rationale: The client should use only crutches measured for the client. When assessing for home safety, the nurse ensures that the client knows to remove any scatter rugs and does not walk on highly waxed floors. The tips should be inspected for wear, and spare crutches and tips should be available if needed. Crutch tips should remain dry. If crutch tips get wet, the client should dry them with a cloth or paper towel. When walking with crutches, both elbows need to be flexed not more than 30 degrees when the palms are on the handle.

Test-Taking Strategy: Focus on the subject, client understanding of instructions of using crutches. Visualize each option and think about the safety associated with each instruction. This will assist in answering correctly.

Level of Cognitive Ability: Evaluating  
Client Needs: Safe and Effective Care Environment  
Integrated Process: Nursing Process—Evaluation  
Content Area: Adult Health: Musculoskeletal  
Health Problem: Adult Health: Musculoskeletal: Skeletal Injury  
Priority Concepts: Mobility; Safety  

746. Answer: 1

Rationale: An altered mental state is an early indication of fat emboli; therefore, clear mentation is a good indicator that a fat embolus is resolving. Eupnea, not minimal dyspnea, is a normal sign. Arterial oxygen levels should be 80 to 100 mm Hg. Oxygen saturation should be higher than 95%.

Test-Taking Strategy: Note the strategic word, most. Knowing that the arterial oxygen and oxygen saturation levels are below normal helps eliminate options 3 and 4. Dyspnea, even at a minimal level, is not normal, so eliminate option 2.

Level of Cognitive Ability: Evaluating  
Client Needs: Physiological Integrity  
Integrated Process: Nursing Process—Evaluation  
Content Area: Adult Health: Musculoskeletal  
Health Problem: Adult Health: Musculoskeletal: Skeletal Injury  
Priority Concepts: Evidence; Perfusion  

747. Answer: 2

Rationale: The earliest symptom of compartment syndrome is paresthesia
(numbness and tingling in the fingers). Other symptoms include pain unrelieved by opioids, pain that increases with limb elevation, and pallor and coolness to the distal limb. Cyanosis is a late sign. Pain that is out of proportion to the severity of the fracture, along with other symptoms associated with the pain, is not an early manifestation.

Test-Taking Strategy: Note the strategic word, early. Knowing that compartment syndrome is characterized by insufficient circulation and ischemia caused by pressure will direct you to the correct option.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Adult Health: Musculoskeletal
Health Problem: Adult Health: Musculoskeletal: Skeletal Injury
Priority Concepts: Client Education; Perfusion

748. Answer: 4

Rationale: Clients with diabetes mellitus are more prone to wound infection, wound separation, and delayed wound healing because of the disease. Postoperative hemorrhage and edema of the residual limb are complications in the immediate postoperative period that apply to any client with an amputation. Slight redness of the incision is considered normal, as long as the incision is dry and intact.

Test-Taking Strategy: Note the strategic word, most, and focus on the subject, complications following surgery for the client with diabetes mellitus. Recalling that diabetes mellitus increases the client’s chances of developing infection and delayed wound healing will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Musculoskeletal
Health Problem: Adult Health: Musculoskeletal: Amputation
Priority Concepts: Glucose Regulation; Tissue Integrity

749. Answer: 3

Rationale: If the client with an amputation has a cast or elastic compression bandage that slips off, the nurse must wrap the residual limb immediately with another elastic compression bandage. Otherwise, excessive edema will form rapidly, which could cause a significant delay in rehabilitation. If the client had a cast that slipped off, the nurse would have to call the PHCP so that a new one could be applied. Elevation on 1 pillow is not going to impede the development of edema greatly once compression is released. Ice would be of limited value in controlling edema from this cause. If the PHCP were called, the prescription likely would be to reapply the compression dressing anyway.

Test-Taking Strategy: Note the strategic word, immediate, and focus on the data in
the question. Recalling that excessive edema can form rapidly in the residual limb will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Adult Health: Musculoskeletal  
**Health Problem:** Adult Health: Musculoskeletal: Amputation  
**Priority Concepts:** Clinical Judgment; Tissue Integrity  
**Reference:** Lewis et al. (2017), p. 1487.

750. **Answer:** 3

**Rationale:** Low back pain that radiates down 1 leg (sciatica) is consistent with herniated lumbar disk. The nurse assesses the client to see whether the pain is aggravated by events that increase intraspinal pressure, such as bending, lifting, sneezing, and coughing, or by lifting the leg straight up while supine (straight leg-raising test). Bed rest, heat (or sometimes ice), and nonsteroidal antiinflammatory drugs (NSAIDs) usually relieve back pain.

**Test-Taking Strategy:** Focus on the **subject**, factors that aggravate back pain. Think about how each item in the options would relieve or exacerbate back pain. Recall that bed rest, heat (or sometimes ice), and NSAIDs usually relieve back pain, whereas bending, lifting, and straining aggravate it.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Musculoskeletal  
**Health Problem:** Adult Health: Musculoskeletal: Intervertebral Disc Herniation  
**Priority Concepts:** Mobility; Pain  

751. **Answer:** 1

**Rationale:** The nursing assessment conducted after spinal surgery is similar to that done after other surgical procedures. For this specific type of surgery, the nurse assesses the neurovascular status of the lower extremities, watches for signs and symptoms of infection, and inspects the surgical site for evidence of cerebrospinal fluid leakage (drainage is clear and tests positive for glucose). A mild temperature is expected after insertion of hardware, but a temperature of 101.6° F (38.7° C) should be reported.

**Test-Taking Strategy:** Note the **strategic word**, most. **Determine if an abnormality exists.** Thus, you are looking for the option that has the greatest deviation from normal. Options 2 and 4 are expected after surgery and, although the nurse tries to minimize discomfort, the client is likely to have some discomfort, even with proper analgesic use. The words **old** and **outlined** in option 3 indicate that this is not a new occurrence. This leaves the temperature of 101.6° F (38.7° C), which is excessive and should be reported.

**Level of Cognitive Ability:** Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Musculoskeletal
Health Problem: Adult Health: Musculoskeletal: Skeletal Injury
Priority Concepts: Clinical Judgment; Infection

752. Answer: 2

Rationale: In addition to the presence of clinical manifestations, gout is diagnosed by the presence of persistent hyperuricemia, with a uric acid level higher than 8 mg/dL (480 mcmol/L); a normal value for a male ranges from 4.0 to 8.5 mg/dL (240–501 mcmol/L) and for a female, from 2.7 to 7.3 mg/dL (160–430 mcmol/L). Options 1, 3, and 4 indicate normal laboratory values. In addition, the presence of uric acid in an aspirated sample of synovial fluid confirms the diagnosis.

Test-Taking Strategy: Focus on the subject, manifestation of gout. Use knowledge of normal laboratory values. Recalling that increased uric acid levels occur in gout and noting that the correct option has the only abnormal value will assist you in answering the question.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Musculoskeletal
Health Problem: Adult Health: Musculoskeletal: Gout
Priority Concepts: Cellular Regulation; Clinical Judgment

753. Answer: 4

Rationale: Buck’s (extension) traction is a type of skin traction often applied after hip fracture before the fracture is reduced in surgery. Traction reduces muscle spasms and helps immobilize the fracture. Traction does not allow for bony healing to begin or provide rigid immobilization. Traction does not lengthen the leg for the purpose of preventing blood vessel severance. This type of traction involves pulleys and wheels, not pins and screws.

Test-Taking Strategy: Focus on the subject, use of traction following a hip fracture. Read each option carefully and note that each option has more than one part. All parts of the option need to be correct in order for the answer to be correct. Noting the words provides comfort and fracture immobilization will direct you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Adult Health: Musculoskeletal
Health Problem: Adult Health: Musculoskeletal: Skeletal Injury
Priority Concepts: Clinical Judgment; Mobility
I. Skeletal Muscle Relaxants
   A. Description
      1. Skeletal muscle relaxants (Box 61-1) act directly on the neuromuscular junction or act indirectly on the central nervous system (CNS).
      2. Centrally acting muscle relaxants depress neuron activity in the spinal cord or brain.
      3. Peripherally acting muscle relaxants act directly on the skeletal muscles, interfering with calcium release from muscle tubules and thus preventing the fibers from contracting.
      4. Skeletal muscle relaxants are used to prevent or relieve muscle spasms and treat spasticity associated with spinal cord disease or lesions, acute painful musculoskeletal conditions, and chronic debilitating disorders such as multiple sclerosis, stroke (brain attacks), or cerebral palsy.
      5. Skeletal muscle relaxants are contraindicated in clients with severe liver, renal, or heart disease; these medications are often metabolized in the liver or excreted by the kidneys.
      6. Skeletal muscle relaxants should not be taken with CNS depressants, such as barbiturates, opioids, alcohol, sedatives, hypnotics, or tricyclic antidepressants, unless specifically prescribed.
   B. Side and adverse effects
      1. Dizziness and hypotension
      2. Drowsiness and muscle weakness
      3. Dry mouth
      4. Gastrointestinal upset
C. Interventions

1. Obtain a medical history and ask about current medications being taken.
2. Monitor vital signs.
3. Monitor for CNS effects.
5. Assess involved joints and muscles for pain and mobility.
7. Instruct the client to take the medication with food to decrease gastrointestinal upset.
8. Instruct the client to report adverse effects.
9. Instruct the client to avoid alcohol and CNS depressants.
10. Instruct the client to avoid activities requiring alertness, such as driving or operating equipment.

D. Nursing considerations

1. Baclofen
   a. Baclofen causes CNS effects such as drowsiness, dizziness, weakness, and fatigue and nausea, constipation, and urinary retention.
   b. Administer with caution in the client with renal or hepatic dysfunction or a seizure disorder.
   c. Baclofen can be administered by the primary health care provider (PHCP) through intrathecal infusion using an implantable pump or by direct intrathecal administration over 1 minute.
   d. Instruct the client with an implantable pump to maintain medication refill appointments to prevent the pump from emptying and experiencing sudden withdrawal symptoms, which could be life-threatening.

Monitor liver function tests when a client is taking a skeletal muscle relaxant, because hepatotoxicity can occur.
2. Carisoprodol
   a. Advise the client to take the medication with food to prevent gastrointestinal upset.
   b. Instruct the client to report any rash or hypersensitivity to the PHCP.

3. Chlorzoxazone
   a. Monitor the client for hypersensitivity reactions such as urticaria, redness or itching, and possibly angioedema.
   b. Chlorzoxazone may cause malaise and may cause the urine to turn orange or red.
   c. Can cause hepatitis and hepatic necrosis.

4. Cyclobenzaprine
   a. Cyclobenzaprine is contraindicated in clients who have received monoamine oxidase inhibitors (MAOIs) within 14 days of initiation of cyclobenzaprine therapy and in clients with cardiac disorders.
   b. Cyclobenzaprine has significant anticholinergic (atropine-like) effects and should be used with caution in clients with a history of urinary retention, angle-closure glaucoma, or increased intraocular pressure.
   c. Cyclobenzaprine should be used only for short-term therapy (2 to 3 weeks).

5. Dantrolene
   a. Dantrolene acts directly on skeletal muscles to relieve spasticity.
   b. Liver damage is the most serious adverse effect.
   c. Liver function values should be monitored before the initiation of treatment and during treatment.
   d. Dantrolene can cause gastrointestinal bleeding, urinary frequency, impotence, photosensitivity, rash, and muscle weakness.
e. Instruct the client to wear protective clothing when in the sun.
f. Instruct the client to notify the PHCP if rash, bloody or tarry stools, or yellow discoloration of the skin or eyes occurs.

6. Diazepam
   a. Acts on the CNS to suppress spasticity; does not affect skeletal muscle directly
   b. Sedation commonly occurs.

7. Methocarbamol
   a. The parenteral form is contraindicated in clients with renal impairment.
   b. The parenteral form can cause hypotension, bradycardia, anaphylaxis, and seizures, especially when the medication is given too rapidly.
   c. Monitor site for extravasation, which can result in thrombophlebitis and tissue sloughing.
   d. Methocarbamol may cause the urine to turn brown, black, or green.
   e. Inform the client to notify the PHCP if blurred vision, nasal congestion, urticaria, or rash occurs.

8. Tizanidine and metaxalone: Can cause liver damage
9. Orphenadrine has significant anticholinergic (atropine-like) effects and should be used with caution in clients with a history of urinary retention, angle-closure glaucoma, or increased intraocular pressure.

II. Antigout Medications
   A. Description
   1. Antigout medications (allopurinol, colchicine, probenecid) reduce uric acid production and increase uric acid excretion (uricosuric) to prevent or relieve gout or to manage hyperuricemia.
   2. Nonsteroidal antiinflammatory drugs (NSAIDs) are used for their antiinflammatory effects and to relieve pain during an acute gouty attack (see Chapter 59 for information on NSAIDs).
3. Glucocorticoids may be prescribed to reduce inflammation during an acute gout attack (see Chapter 47 for information on glucocorticoids).

4. Antigout medications should be used cautiously in clients with gastrointestinal, renal, cardiac, or hepatic disease.

B. Side and adverse effects
1. Headaches
2. Nausea, vomiting, and diarrhea
3. Blood dyscrasias, such as bone marrow depression
4. Flushed skin and rash
5. Uric acid kidney stones
6. Sore gums
7. Metallic taste

C. Interventions
1. Assess serum uric acid levels.
2. Monitor intake and output.
3. Maintain a fluid intake of at least 2000 to 3000 mL/day to prevent kidney stones.
4. Monitor complete blood cell count and renal and liver function studies.
5. Instruct the client to avoid alcohol and caffeine, because these products can increase uric acid levels.
6. Encourage the client to comply with therapy to prevent elevated uric acid levels, which can trigger a gout attack.
7. Instruct the client to avoid foods high in purine as prescribed, such as wine, alcohol, organ meats, sardines, salmon, scallops, and gravy.
8. Instruct the client to take the medication with food to decrease gastric irritation.
9. Instruct the client to report adverse effects to the PHCP.
10. Caution the client not to take aspirin with these medications, because this could trigger a gout attack.

D. Nursing considerations
1. Allopurinol
   a. Can increase the effect of warfarin and
oral hypoglycemic agents

b. Instruct the client not to take large doses of vitamin C while taking allopurinol, because kidney stones may occur.

c. Hypersensitivity syndrome (rare) can occur, characterized by rash, fever, eosinophilia, and liver and kidney alterations (medication is withheld and the PHCP is notified).

d. Advise the client to minimize exposure to sunlight and have an annual eye examination, because visual changes can occur from prolonged use of allopurinol.

2. Colchicine

a. Used with caution in older clients, debilitated clients, and clients with cardiac, renal, and/or gastrointestinal disease.

b. If gastrointestinal symptoms occur (nausea, vomiting, diarrhea, and abdominal pain), the medication is withheld and the PHCP is notified.

3. Probenecid

a. Mild gastrointestinal effects can occur and can be reduced by taking the medication with food.

b. Aspirin and other salicylates interfere with the uricosuric action of the medication.

The concurrent use of antigout medications and aspirin causes elevated uric acid levels; the client should be instructed to take acetaminophen if prescribed rather than aspirin.

III. Antiarthritic Medications (Box 61-2)

A. Description (Fig. 61-1)

1. Rheumatoid arthritis occurs as inflammation progresses into the synovia, cartilage, and bone; if this inflammation is not controlled, it will lead to joint destruction, thus affecting client mobility and comfort.

2. The focus of treatment is early diagnosis and
aggressive treatment to preserve joint function.

3. Medication therapy includes NSAIDs, glucocorticoids, and disease-modifying antirheumatic drugs (DMARDs).

4. Gold salts: Use of gold salts has decreased, but their purpose is to reduce the progression of joint damage caused by arthritic processes. Gold toxicity, characterized by pruritus, rash, metallic taste, stomatitis, and diarrhea, can occur; if toxicity occurs, dimercaprol may be prescribed to enhance gold excretion.

B. DMARDs

1. Description
   a. DMARDs are effective antirheumatic medications that are used to slow the degenerative effects of the disorder.
   b. DMARDs are usually prescribed secondary to NSAIDs but are often the first choice in the treatment of severe arthritis.

2. Common side and adverse effects of DMARDs
   include injection site inflammation and pain, ecchymosis, and edema; pancytopenia and infection; fatigue, headache, nausea, vomiting, and flu-like symptoms; and allergic response.

3. Interventions
   a. Instruct the client to monitor for signs of infection and report signs to the PHCP.
   b. Monitor the injection site for signs of irritation, pain, inflammation, and swelling.
   c. Instruct the client to consult with the PHCP before receiving live vaccines and to avoid exposure to infections.
   d. Inform the client about the importance of laboratory tests for neutrophil counts, white blood cell counts, and platelet counts before initiation of treatment and during treatment.

4. Anakinra: Injection site reactions are common (pruritus, erythema, rash, pain).

5. Adalimumab
   a. Injection site reactions are common.
   b. Has been associated with neurological
6. Azathioprine: Immunosuppressive and antiinflammatory actions; toxic effects include hepatitis and blood dyscrasias.
7. Cyclosporine: Immunosuppressive actions; can cause nephrotoxicity
8. Etanercept
   a. Injection site reactions are common.
   b. Poses a risk for heart failure; has been associated with CNS demyelinating disorders and hematological disorders
9. Hydroxychloroquine: Associated with retinal damage; inform the client to contact the PHCP if visual disturbances occur.
10. Leflunomide: Side and adverse effects include diarrhea, respiratory infection, reversible alopecia, rash, and nausea; medication is hepatotoxic.
11. Methotrexate: Can cause hepatic fibrosis, bone marrow suppression, gastrointestinal ulceration, and pneumonitis
12. Penicillamine: Can cause bone marrow suppression and autoimmune disorders
13. Infliximab: Can cause infusion reactions (fever, chills, pruritus, urticaria, chest pain); medication is hepatotoxic.
14. Rituxan: Can cause increased thirst or urination, swelling of the hands or feet, or tingling of the hands or feet; the PHCP should be notified if any of these occur.
15. Sulfasalazine: Can cause gastrointestinal and dermatological reactions, bone marrow suppression, and hepatitis

C. NSAIDs may be prescribed for their antiinflammatory and analgesic effects (see Chapter 59 for information on NSAIDs).
D. Glucocorticoids may be prescribed for their antiinflammatory effects (see Chapter 47 for information on glucocorticoids).

IV. Medications to Prevent and Treat Osteoporosis
   A. Description
   1. Osteoporosis is characterized by decreased bone mass and increased bone fragility.
   2. Calcium and vitamin D supplementation can reduce the risk of osteoporosis; calcium maximizes bone growth early in life and maintains bone integrity later in life, and vitamin D ensures calcium absorption (see Chapter 47 for information on calcium and vitamin D
supplements).

3. Treatment is aimed at reducing the occurrence of fractures by maintaining or increasing bone strength.

4. Medications that decrease bone resorption (antiresorptive) and medications that promote bone formation are used (Box 61-3).

5. Antiresorptive medications include raloxifene, calcitonin, and bisphosphonates.

6. Teriparatide promotes bone growth.

B. Interventions

1. Calcitonin-salmon
   a. Calcitonin is secreted by the thyroid gland and inhibits osteoclastic bone resorption.
   b. Instruct the client on how to administer the intranasal or subcutaneous form, depending on the route prescribed.
   c. Intranasal route: Examine the nares for irritation; alternate nostrils for doses.
   d. When calcitonin is taken, it is important to monitor for hypocalcemia.

2. Bisphosphonates
   a. Bisphosphonates inhibit osteoclast-mediated bone resorption, thereby increasing total bone mass.
   b. Bisphosphonates include alendronate, risedronate, ibandronate, pamidronate, and zoledronic acid.
   c. Contraindicated for clients with esophageal disorders that can impede swallowing and for clients who cannot sit or stand for at least 30 minutes (60 minutes with ibandronate)
   d. Adverse effects include esophagitis, muscle pain, and ocular problems; the client is instructed to contact the PHCP if adverse effects occur.

Because of the risk of esophagitis,
bisphosphonates must be administered in the morning before eating or drinking with a full glass of water; the client must then remain sitting or standing and postpone ingesting anything for at least 30 minutes (60 minutes with ibandronate).

3. Raloxifene
   a. Antiresorptive medication (nonbisphosphonate)
   b. Contraindicated in clients who have a history of venous thrombotic events
   c. Needs to be discontinued 72 hours prior to prolonged immobilization periods (such as with periods of extended bed rest)
   d. Instruct the client to avoid extended periods of restricted activity (such as when traveling).

4. Denosumab: A monoclonal antibody that treats osteoporosis and hypercalcemia; can also treat bone cancer and bone problems in those who have cancer.

5. Teriparatide
   a. Teriparatide stimulates new bone formation, thus increasing bone mass.
   b. Teriparatide is a portion of the human parathyroid hormone and works by increasing the action of osteoblasts.
   c. Is usually reserved for clients at high risk for fractures
   d. Has been associated with the development of bone cancer

NSAIDs such as ibuprofen, indomethacin, and naproxen are commonly used to treat musculoskeletal pain. Acetaminophen may also be used to treat this type of pain as well and are often considered first-line treatments.

**Box 61-1**

**Skeletal Muscle Relaxants**

- Baclofen
- Carisoprodol
Box 61-2

Antiarthritic Medications

- Anakinra
- Adalimumab
- Azathioprine
- Cyclosporine
- Etanercept
- Hydroxychloroquine
- Infliximab
- Leflunomide
- Methotrexate
- Penicillamine
- Rituximab
- Sulfasalazine

**FIG. 61-1** Progressive joint degeneration in rheumatoid arthritis. **A,** Healthy joint. **B,** Inflammation of synovial membrane. **C,** Onset of pannus formation and cartilage erosion. **D,** Pannus formation progresses and cartilage deteriorates further. **E,** Complete destruction of joint cavity, together with fusion of articulating bones.
Box 61-3

Medications to Prevent or Treat Osteoporosis

- Calcium and vitamin D
- Alendronate
- Calcitonin-salmon
- Denosumab
- Ibandronate
- Pamidronate
- Raloxifene
- Risedronate
- Teriparatide
- Zoledronic acid

Practice Questions

754. A client has been on treatment for rheumatoid arthritis for 3 weeks. During the administration of etanercept, which is most important for the nurse to assess?
1. The injection site for itching and edema
2. The white blood cell counts and platelet counts
3. Whether the client is experiencing fatigue and joint pain
4. Whether the client is experiencing a metallic taste in the mouth and a loss of appetite

755. Allopurinol is prescribed for a client and the nurse provides medication instructions to the client. Which instruction should the nurse provide?
1. Drink 3000 mL of fluid a day.
2. Take the medication on an empty stomach.
3. The effect of the medication will occur immediately.
4. Any swelling of the lips is a normal expected response.

756. Colchicine is prescribed for a client with a diagnosis of gout. The nurse reviews the client’s record, knowing that this medication would be used with caution in which disorder?
1. Myxedema
2. Kidney disease
3. Hypothyroidism
4. Diabetes mellitus

757. Alendronate is prescribed for a client with osteoporosis, and the nurse is providing instructions on administration of the medication. Which instruction should the nurse provide?
1. Take the medication at bedtime.
2. Take the medication in the morning with breakfast.
3. Lie down for 30 minutes after taking the medication.
4. Take the medication with a full glass of water after rising in the morning.

758. The nurse is preparing discharge instructions for a client who sustained a skeletal muscle injury and is receiving baclofen. Which instruction should be included in the teaching plan?
   1. Restrict fluid intake.
   2. Avoid the use of alcohol.
   3. Stop the medication if diarrhea occurs.
   4. Notify the primary health care provider (PHCP) if fatigue occurs.

759. The nurse is analyzing the laboratory studies on a client receiving dantrolene to treat muscle spasms from an injury. Which laboratory test would identify an adverse effect associated with the administration of this medication?
   1. Platelet count
   2. Creatinine level
   3. Liver function tests
   4. Blood urea nitrogen level

760. Cyclobenzaprine is prescribed for a client for muscle spasms, and the nurse is reviewing the client’s record. Which disorder, if noted in the record, would indicate a need to contact the primary health care provider about the administration of this medication?
   1. Glaucoma
   2. Emphysema
   3. Hypothyroidism
   4. Diabetes mellitus

761. In monitoring a client’s response to disease-modifying antirheumatic drugs (DMARDs), which assessment findings would the nurse consider acceptable responses? Select all that apply.
   1. Control of symptoms during periods of emotional stress
   2. Normal white blood cell, platelet, and neutrophil counts
   3. Radiological findings that show no progression of joint degeneration
   4. An increased range of motion in the affected joints 3 months into therapy
   5. Inflammation and irritation at the injection site 3 days after the injection is given
   6. A low-grade temperature on rising in the morning that remains throughout the day

762. The nurse is administering an intravenous dose of methocarbamol to a client with a muscle skeletal injury. For which adverse effect should the nurse monitor?
   1. Tachycardia
   2. Rapid pulse
   3. Bradycardia
   4. Hypertension
Rationale: Infection and pancytopenia are adverse effects of etanercept. Laboratory studies are performed prior to and during medication treatment. The appearance of abnormal white blood cell counts and abnormal platelet counts can alert the nurse to a potentially life-threatening infection. Injection site itching is a common occurrence following administration. A metallic taste and loss of appetite are not common signs of adverse effects of this medication.

Test-Taking Strategy: Note the strategic words, most important. Option 4 can be eliminated because this is not a common adverse effect. In early treatment, residual fatigue and joint pain may still be apparent. For the remaining options, the correct option monitors for a hematological disorder, which could indicate a reason for discontinuing this medication and should be reported.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Pharmacology: Musculoskeletal Medications: Antiarthritic Medications
Health Problem: Adult Health: Musculoskeletal: Rheumatoid arthritis and osteoarthritis
Priority Concepts: Clinical Judgment; Safety

Rationale: Clients taking allopurinol are encouraged to drink 3000 mL of fluid a day, unless otherwise contraindicated. A full therapeutic effect may take 1 week or longer. Allopurinol is to be given with, or immediately after, meals or milk. A client who develops a rash, irritation of the eyes, or swelling of the lips or mouth should contact the primary health care provider because this may indicate hypersensitivity.

Test-Taking Strategy: Focus on the subject, client instructions for allopurinol. Option 4 can be eliminated easily because it indicates hypersensitivity, which is not a normal expected response. From the remaining options, recalling that this medication is used to treat gout and recalling the pathophysiology of this disorder will direct you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Pharmacology: Musculoskeletal Medications: Antigout
Health Problem: Adult Health: Musculoskeletal: Gout
Priority Concepts: Client Education; Safety

756. Answer: 2
**Rationale:** Colchicine is used with caution in older clients, debilitated clients, and clients with cardiac, kidney, or gastrointestinal disease. The disorders in options 1, 3, and 4 are not concerns with administration of this medication.

**Test-Taking Strategy:** Focus on the subject, the cautions associated with colchicine. Note that options 1, 3, and 4 are comparable or alike and are endocrine-related disorders. The correct option is different from the others.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Analysis

**Content Area:** Pharmacology: Musculoskeletal Medications: Antigout

**Health Problem:** Adult Health: Musculoskeletal: Gout

**Priority Concepts:** Clinical Judgment; Safety

**Reference:** Lilley et al. (2017), pp. 701, 703.

757. Answer: 4

**Rationale:** Precautions need to be taken with the administration of alendronate to prevent gastrointestinal adverse effects (especially esophageal irritation) and to increase absorption of the medication. The medication needs to be taken with a full glass of water after rising in the morning. The client should not eat or drink anything for 30 minutes following administration and should not lie down after taking the medication.

**Test-Taking Strategy:** Focus on the subject, the administration of alendronate. Recalling that this medication can cause esophageal irritation will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Musculoskeletal Medications: Osteoporosis Medications

**Health Problem:** Adult Health: Musculoskeletal: Osteoporosis

**Priority Concepts:** Client Education; Tissue Integrity

**Reference:** Lilley et al. (2017), p. 542.

758. Answer: 2

**Rationale:** Baclofen is a skeletal muscle relaxant. The client should be cautioned against the use of alcohol and other central nervous system depressants, because baclofen potentiates the depressant activity of these agents. Constipation, rather than diarrhea, is a side effect. Restriction of fluids is not necessary, but the client should be warned that urinary retention can occur. Fatigue is related to a central nervous system effect that is most intense during the early phase of therapy and diminishes with continued medication use. The client does not need to notify the PHCP about fatigue.

**Test-Taking Strategy:** Focus on the subject, teaching points for baclofen. Recalling that baclofen is a skeletal muscle relaxant will direct you easily to the correct option. If you were unsure of the correct option, use general principles related to medication
administration. Alcohol should be avoided with the use of medications.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Pharmacology: Musculoskeletal Medications: Muscle Relaxants  
**Health Problem:** Adult Health: Musculoskeletal: Tissue or ligament injury  
**Priority Concepts:** Client Education; Safety  

759. **Answer:** 3

**Rationale:** Dose-related liver damage is the most serious adverse effect of dantrolene. To reduce the risk of liver damage, liver function tests should be performed before treatment and throughout the treatment interval. Dantrolene is administered at the lowest effective dosage for the shortest time necessary.

**Test-Taking Strategy:** Eliminate options 2 and 4 because these tests assess kidney function and are comparable or alike. From the remaining options, you must recall that this medication affects liver function.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Analysis  
**Content Area:** Pharmacology: Musculoskeletal Medications: Muscle Relaxants  
**Health Problem:** Adult Health: Musculoskeletal: Tissue or ligament injury  
**Priority Concepts:** Cellular Regulation; Tissue Integrity  
**Reference:** Lilley et al. (2017), p. 198.

760. **Answer:** 1

**Rationale:** Because cyclobenzaprine has anticholinergic effects, it should be used with caution in clients with a history of urinary retention, glaucoma, and increased intraocular pressure. Cyclobenzaprine should be used only for a short time (2 to 3 weeks). The conditions in options 2, 3, and 4 are not a concern with this medication.

**Test-Taking Strategy:** Focus on the subject, a contraindication to cyclobenzaprine. Recalling that this medication has anticholinergic effects will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Analysis  
**Content Area:** Pharmacology: Musculoskeletal Medications: Muscle Relaxants  
**Health Problem:** Adult Health: Musculoskeletal: Tissue or ligament injury  
**Priority Concepts:** Collaboration; Safety  
**Reference:** Skidmore-Roth (2017), pp. 300-301.

761. **Answer:** 1, 2, 3, 4

**Rationale:** Because emotional stress frequently exacerbates the symptoms of rheumatoid arthritis, the absence of symptoms is a positive finding. DMARDs are
given to slow the progression of joint degeneration. In addition, an improvement in the range of motion after 3 months of therapy with normal blood work is a positive finding. Temperature elevation and inflammation and irritation at the medication injection site could indicate signs of infection.

**Test-Taking Strategy:** Focus on the **subject**, acceptable responses to therapy. Recalling that signs of an infection can indicate an unexpected and unwanted finding will assist in eliminating options 5 and 6.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Evaluation

**Content Area:** Pharmacology: Musculoskeletal Medications: Antiarthritic Medications

**Health Problem:** Adult Health: Musculoskeletal: Rheumatoid arthritis and osteoarthritis

**Priority Concepts:** Clinical Judgment; Evidence

762. **Answer:** 3

**Rationale:** Intravenous administration of methocarbamol can cause hypotension and bradycardia. The nurse needs to monitor for these adverse effects. Options 1, 2, and 4 are not effects with administration of this medication.

**Test-Taking Strategy:** Eliminate options 1 and 2 first because they are **comparable or alike**. Knowledge about the specific adverse effects related to the intravenous use of this medication will direct you to the correct option. Remember that hypotension and bradycardia can occur with intravenous administration of methocarbamol.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Pharmacology: Musculoskeletal Medications: Muscle Relaxants

**Health Problem:** Adult Health: Musculoskeletal: Tissue or ligament injury

**Priority Concepts:** Clinical Judgment; Safety

Introduction

Pyramid to Success

Pyramid Points focus on the effects of and complications associated with an immune deficiency. Specific focus relates to the nursing care related to the disorder, the impact of the treatment or disorder, and client adaptation. Human immunodeficiency virus and acquired immunodeficiency syndrome is a Pyramid focus, along with protecting the client from infection and preventing the transmission of infection to other individuals. Psychosocial issues relate to social isolation and the body image disturbances that can occur as a result of the immune disorder.

Client Needs: Learning Objectives

Safe and Effective Care Environment

- Acting as an advocate related to the client’s decisions
- Addressing advance directives
- Consulting with the interprofessional health care team
- Ensuring that informed consent for treatments and procedures has been obtained
- Establishing priorities
- Handling hazardous and infectious materials safely
- Implementing standard and other precautions
- Maintaining asepsis
- Maintaining confidentiality regarding diagnosis
- Preventing infection
- Upholding client rights

Health Promotion and Maintenance

- Ensuring that the client receives recommended immunizations
- Implementing health screening measures
- Monitoring for expected body image changes
- Performing physical assessment techniques related to the immune system
- Preventing disease related to infection
- Providing health promotion programs
- Respecting client lifestyle choices
**Psychosocial Integrity**

Assisting in mobilizing appropriate support and resource systems  
Assisting the client and family to cope  
Assisting the client and family to adapt, and solve problems during illness or stressful events  
Considering religious, spiritual, and cultural preferences  
Discussing grief and loss related to death and the dying process  
Promoting a positive environment to maintain optimal quality of life

**Physiological Integrity**

Managing medical emergencies  
Managing pain  
Monitoring for the expected and unexpected responses to treatments  
Optimizing pharmacological treatment  
Promoting nutrition  
Protecting the client from infection  
Providing basic care and comfort  
Reviewing diagnostic test and laboratory test results
CHAPTER 62

Immune Problems

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Immunology; Infection

I. Functions of the Immune System (Fig. 62-1)
   A. Provides protection against invasion by microorganisms from outside the body
   B. Protects the body from internal threats and maintains the internal environment by removing dead or damaged cells

II. Immune Response
   A. T lymphocytes and B lymphocytes
      1. Lymphocytes are produced in the bone marrow and migrate to lymphoid tissue, where they remain dormant until they need to form sensitized lymphocytes for cellular immunity or antibodies for humoral immunity.
      2. Some B lymphocytes lie dormant until a specific antigen enters the body, at which time they greatly increase in number and are available for defense.
      3. Types of T lymphocytes include helper/inducer, suppressor, and cytotoxic/cytolytic.
      4. T and B lymphocytes are necessary for a normal immune response.
   B. Humoral response
      1. Humoral response is immediate.
      2. This type of response provides protection against acute, rapidly developing bacterial and viral infections.
   C. Cellular response
      1. Cellular response is delayed; this is also called delayed hypersensitivity.
      2. This type of response is active against slowly developing bacterial infections and is involved in autoimmune responses, some allergic reactions, and rejection of foreign cells.
III. Immunity

A. Innate immunity
1. Innate immunity is also called native or natural immunity.
2. It is present at birth and includes biochemical, physical, and mechanical barriers of defense, as well as the inflammatory response.

B. Acquired immunity
1. Acquired or adaptive immunity is received passively from the mother’s antibodies, animal serum, or antibodies produced in response to a disease.
2. Immunization produces active acquired immunity.

IV. Immunizations: See Chapter 18 for information about immunizations

V. Laboratory Studies

A. Antinuclear antibody (ANA) determination
1. The ANA determination is a blood test used for the differential diagnosis of rheumatic diseases and for the detection of antinucleoprotein factors and patterns associated with certain autoimmune diseases.
2. The test is negative at a 1:40 dilution, depending on the laboratory.
3. A positive result does not necessarily confirm a disease.
4. The ANA is positive in most individuals diagnosed with systemic lupus erythematosus (SLE); it may also be positive in individuals with systemic sclerosis (scleroderma) or rheumatoid arthritis.
5. An ANA result can be false positive in some individuals.

B. Anti-dsDNA antibody test
1. The anti-dsDNA (double-stranded DNA) antibody test is a blood test done specifically to identify or differentiate DNA antibodies found in SLE.
2. The test supports a diagnosis, monitors disease activity and response to therapy, and establishes a prognosis for SLE.
3. Values: negative, lower than 70 U/mL by enzyme-linked immunosorbent assay (ELISA)

C. Human immunodeficiency virus (HIV) testing
1. CD4+ T cell count
   a. Monitors the progression of HIV
   b. As the disease progresses, usually the number of CD4+ T cells decreases, with a resultant decrease in immunity.
   c. The normal CD4+ T cell count is 2170
between 500 and 1600 cells/L.

d. In general, the immune system remains healthy with CD4+ T cell counts higher than 500 cells/L.

e. Immune system problems occur when the CD4+ T cell count is between 200 and 499 cells/L.

f. Severe immune system problems occur when the CD4+ T cell count is lower than 200 cells/L.

2. CD4-to-CD8 ratio
   a. Monitors progression of HIV
   b. Normal ratio is approximately 2:1.

3. Viral culture involves placing the infected client’s blood cells in a culture medium and measuring the amount of reverse transcriptase activity over a specified period of time.

4. Viral load testing measures the presence of HIV viral genetic material (RNA) or another viral protein in the client’s blood.

5. The p24 antigen assay quantifies the amount of HIV viral core protein in the client’s serum.

6. Oral testing for HIV
   a. Uses a device that is placed against the gum and cheek for 2 minutes
   b. Fluid (not saliva) is drawn into an absorbable pad, which, in an HIV-positive individual, contains antibodies.
   c. The pad is placed in a solution, and a specified observable change is noted if the test result is positive.
   d. If the result is positive, a blood test is needed to confirm the results.

7. Home test kits for HIV
   a. In one at-home test kit, a drop of blood is placed on a test card with a special code number; the card is mailed to a laboratory for testing for HIV antibodies.
   b. The individual receives the results by calling a special telephone number and entering the special code number; test results are then given.

8. Nursing considerations
   a. Maintain issues of confidentiality surrounding HIV and acquired immunodeficiency syndrome (AIDS)
D. Skin testing

1. Description
   a. The administration of an allergen to the surface of the skin or into the dermis
   b. Administered by patch, scratch, or intradermal techniques

2. Preprocedure interventions
   a. Discontinue systemic corticosteroids or antihistamine therapy 5 days before the test as prescribed.
   b. Ensure that informed consent was obtained.

3. Postprocedure interventions
   a. Record the site, date, and time of the test.
   b. Record the date and time for follow-up site reading.
   c. Have the client remain in the waiting room or office for at least 30 minutes after the injections to monitor for adverse effects.
   d. Inspect the site for erythema, papules, vesicles, edema, and wheal (Fig. 62-2).
   e. Measure flare along with the wheal, and document the size and other findings.
   f. Provide the client with a list of potential allergens, if identified.

Have resuscitation equipment available if skin testing is performed, because the allergen may induce an anaphylactic reaction.

VI. Hypersensitivity and Allergy

A. Description
   1. An abnormal, individual response to certain substances that normally do not trigger such an exaggerated reaction.
   2. In some types of allergies, a reaction occurs on a second and subsequent contact with the allergen.
   3. Skin testing may be done to determine the allergen.
B. Assessment
   1. History of exposure to allergens
   2. Itching, tearing, and burning of eyes and skin
   3. Rashes
   4. Nose twitching, nasal stuffiness
C. Interventions
   1. Identification of the specific allergen
   2. Management of the symptoms with antihistamines, antiinflammatory agents, and/or corticosteroids
   3. Ointments, creams, wet compresses, and soothing baths for local reactions
   4. Desensitization programs may be recommended.

VII. Anaphylaxis
   A. Description
      1. A serious and immediate hypersensitivity reaction that releases histamine from the damaged cells
      2. Anaphylaxis can be systemic or cutaneous (localized).
   B. Assessment (Fig. 62-3)
   C. Interventions (see Priority Nursing Actions)

### Priority Nursing Actions

**Anaphylactic Reaction**
1. Quickly assess respiratory status and maintain a patent airway.
2. Call the primary health care provider (PHCP) and Rapid Response Team.
3. Administer oxygen.
4. Start an intravenous (IV) line and infuse normal saline.
5. Prepare to administer diphenhydramine and epinephrine.

**Reference**

VIII. Latex Allergy
   A. Description
      1. Latex allergy is a hypersensitivity to latex.
      2. The source of the allergic reaction is thought to be the proteins in the natural rubber latex or the various chemicals used in the manufacturing process of latex gloves.
      3. Symptoms of the allergy can range from mild contact dermatitis to moderately severe symptoms of rhinitis, conjunctivitis, urticaria, and bronchospasm to severe life-threatening anaphylaxis.
   B. Common routes of exposure (Box 62-1)
1. Cutaneous: Natural latex gloves and latex balloons
2. Percutaneous and parenteral: Intravenous lines and catheters; hemodialysis equipment
3. Mucosal: Use of latex condoms, catheters, airways, and nipples
4. Aerosol: Aerosolization of powder from latex gloves can occur when gloves are dispensed from the box or when gloves are removed from the hands.

C. At-risk individuals
1. Health care workers
2. Individuals who work in the rubber industry
3. Individuals having multiple surgeries
4. Individuals with spina bifida
5. Individuals who wear gloves frequently, such as food handlers, hairdressers, and auto mechanics
6. Individuals allergic to kiwis, bananas, pineapples, tropical fruits, grapes, avocados, potatoes, hazelnuts, and water chestnuts

D. Assessment
1. Anaphylaxis or type 1 hypersensitivity is a response to natural rubber latex (Fig. 62-4; also see Fig. 62-3).
2. A delayed type 4 hypersensitivity reaction can occur; symptoms of contact dermatitis include pruritus, edema, erythema, vesicles, papules, and crusting and thickening of the skin and can occur within 6 to 48 hours following exposure.

E. Interventions (Box 62-2)

IX. Immunodeficiency
A. Description
1. **Immunodeficiency** is the absence or inadequate production of immune bodies.
2. The disorder can be congenital (primary) or acquired (secondary).
3. Treatment depends on the inadequacy of immune bodies and its primary cause.

B. Assessment
1. Factors that decrease immune function
2. Frequent infections
3. Nutritional status
4. Medication history, such as use of corticosteroids for long periods
5. History of alcohol or drug abuse
C. Interventions

1. Protect the client from infection.
2. Promote a balanced diet with adequate nutrition.
3. Use strict aseptic technique for all procedures.
4. Provide psychosocial care regarding lifestyle changes and role changes.
5. Instruct the client in measures to prevent infection.
6. Instruct the client to wear a MedicAlert bracelet.

X. Autoimmune Disease

A. Description

1. Body is unable to recognize its own cells as a part of itself.
2. Autoimmune disease can affect collagenous tissue.

B. Systemic lupus erythematosus (SLE)

1. Description
   a. Chronic, progressive, systemic inflammatory disease that can cause major organs and systems to fail
   b. Connective tissue and fibrin deposits collect in blood vessels on collagen fibers and on organs.
   c. The deposits lead to necrosis and inflammation in blood vessels, lymph nodes, gastrointestinal tract, and pleura.
   d. No cure for the disease is known, but remissions are frequently experienced by clients who manage their care well.

2. Causes
   a. The cause of SLE is unknown but is believed to be a defect in immunological mechanisms, with a genetic origin.
   b. Precipitating factors include medications, stress, genetic factors, sunlight or ultraviolet light, and pregnancy.
   c. Discoid lupus erythematosus is possible with some medications but totally disappears after the medication is stopped; the only manifestation is the
skin rash that occurs in lupus.

3. Assessment

a. Assess for precipitating factors.
b. Erythema of the face (malar rash; also called a butterfly rash)
c. Dry, scaly, raised rash on the face or upper body
d. Fever
e. Weakness, malaise, and fatigue
f. Anorexia
g. Weight loss
h. Photosensitivity
i. Joint pain
j. Erythema of the palms
k. Anemia
l. Positive ANA test and lupus erythematosus preparation
m. Elevated erythrocyte sedimentation rate (ESR) and C-reactive protein level

4. Interventions

a. Monitor skin integrity and provide frequent oral care.
b. Instruct the client to clean the skin with a mild soap, avoiding harsh and perfumed substances.
c. Assist with the use of ointments and creams for the rash as prescribed.
d. Identify factors contributing to fatigue.
e. Administer iron, folic acid, or vitamin supplements as prescribed if anemia occurs.
f. Provide a high-vitamin and high-iron diet.
g. Provide a high-protein diet if there is no evidence of kidney disease.
h. Instruct in measures to conserve energy, such as pacing activities and balancing rest with exercise.
i. Administer topical or systemic corticosteroids, salicylates, and nonsteroidal anti-inflammatory drugs as prescribed for pain and inflammation.
j. Administer medications to decrease the inflammatory response as prescribed.
k. Monitor intake and output, as well as daily weight for signs of fluid overload if corticosteroids are used.
l. Instruct the client to avoid exposure to sunlight and ultraviolet light.
m. Monitor for proteinuria and red cell casts in the urine.
n. Monitor for bruising, bleeding, and injury.
o. Assist with plasmapheresis as prescribed to remove autoantibodies and immune complexes from the blood before organ damage occurs.
p. Monitor for signs of organ involvement such as pleuritis, nephritis, pericarditis, coronary artery disease, hypertension, neuritis, anemia, and peritonitis.
q. Note that lupus nephritis occurs early in the disease process.
r. Provide supportive therapy as major organs become affected.
s. Provide emotional support and encourage the client to verbalize feelings.
t. Provide information regarding support groups and encourage the use of community resources.

For the client with SLE, monitor the blood urea nitrogen and creatinine levels frequently for signs of renal impairment.

C. Scleroderma (systemic sclerosis)

1. Description
   a. Scleroderma is a chronic connective tissue disease, similar to SLE, that is characterized by inflammation, fibrosis, and sclerosis.
   b. This disorder affects the connective tissue throughout the body.
   c. It causes fibrotic changes involving the skin, synovial membranes, esophagus, heart, lungs, kidneys, and gastrointestinal tract.
   d. Treatment is directed toward forcing the disease into remission and slowing its progress.
2. Assessment

a. Pain

b. Stiffness and muscle weakness

c. Pitting edema of the hands and fingers that progresses to the rest of the body

d. Taut and shiny skin that is free from wrinkles

e. Skin tissue is tight, hard, and thick; loses its elasticity; and adheres to underlying structures.

f. Dysphagia

g. Decreased range of motion

h. Joint contractures

i. Inability to perform activities of daily living

3. Interventions

a. Encourage activity as tolerated.

b. Maintain a constant room temperature.

c. Provide small frequent meals, eliminating foods that stimulate gastric secretions, such as spicy foods, caffeine, and alcohol.

d. Monitor for esophageal involvement; if present, advise the client to sit up for 1 to 2 hours after meals. Using additional pillows and raising the head of the bed on blocks may help reduce nocturnal reflux.

e. Provide supportive therapy as the major organs become affected.

f. Administer corticosteroids as prescribed for inflammation.

g. Provide emotional support and encourage the use of resources as necessary.

D. Polyarteritis nodosa

1. Description

a. Polyarteritis nodosa is a collagen disease; it is a form of systemic vasculitis that causes inflammation of the arteries in visceral organs, brain, and skin.

b. Treatment is similar to the treatment for SLE.

c. Polyarteritis nodosa affects middle-aged
The cause is unknown and the prognosis is poor.
Renal disorders and cardiac involvement are the most frequent causes of death.

2. Assessment

a. Malaise and weakness
b. Low-grade fever
c. Severe abdominal pain
d. Bloody diarrhea
e. Weight loss
f. Elevated ESR

3. Interventions: Refer to interventions for SLE.

E. Pemphigus

1. Description

a. Pemphigus is a rare autoimmune disease that occurs predominantly between middle age and old age.
b. The cause is unknown, and the disorder is potentially fatal.
c. Treatment is aimed at suppressing the immune response and blister formation.

2. Assessment

a. Fragile, partial-thickness lesions bleed, weep, and form crusts when bullae are disrupted.
b. Debilitation, malaise, pain, and dysphagia
c. Nikolsky’s sign: Separation of the epidermis caused by rubbing the skin
d. Leukocytosis, eosinophilia, foul-smelling discharge from skin

3. Interventions

a. Provide supportive care.
b. Provide oral hygiene and increase fluid intake.
c. Soothe oral lesions.
d. Assist with soothing baths, as prescribed for relief of symptoms.
e. Administer topical or systemic antibiotics as prescribed for secondary
XI. Goodpasture’s Syndrome

A. Description
1. An autoimmune disorder; autoantibodies are made against the glomerular basement membrane and alveolar basement membrane.
2. It is most common in males and young adults who smoke; the exact cause is unknown.
3. The lungs and the kidneys are affected primarily, and the disorder usually is not diagnosed until significant pulmonary or renal involvement occurs.

B. Assessment
1. Clinical manifestations indicating pulmonary and renal involvement
2. Shortness of breath
3. Hemoptysis
4. Decreased urine output
5. Edema and weight gain
6. Hypertension and tachycardia

C. Interventions
1. Focus on suppressing the autoimmune response with medications such as corticosteroids and on plasmapheresis (filtration of the plasma to remove some proteins and autoantibodies).
2. Provide supportive therapy for pulmonary and renal involvement.

XII. Lyme Disease

A. Description
1. An infection caused by the spirochete *Borrelia burgdorferi*, acquired from a tick bite (ticks live in wooded areas and survive by attaching to a host)
2. Infection with the spirochete stimulates inflammatory cytokines and autoimmune mechanisms.

B. Assessment ([Box 62-3; Fig. 62-5])
1. The typical ring-shaped rash of Lyme disease does not occur in all clients. Many clients never develop a rash.
2. If a rash does occur, it can occur anywhere on the body, not only at the site of the bite.

C. Interventions
1. Gently remove the tick with tweezers, wash the skin
with antiseptic, and dispose of the tick by flushing it down the toilet; the tick may also be placed in a sealed jar so that the primary health care provider can inspect it and determine its type.

2. Perform a blood test 4 to 6 weeks after a bite to detect the presence of the disease (testing before this time is not reliable).

3. Instruct the client in the administration of antibiotics as prescribed; these are initiated immediately (even before the blood testing results are known).

4. Instruct the client to avoid areas that contain ticks, such as wooded grassy areas, especially in the summer months.

5. Instruct the client to wear long-sleeved tops, long pants, closed shoes, and hats while outside.

6. Instruct the client to spray the body with tick repellent before going outside.

7. Instruct the client to examine the body when returning inside for the presence of ticks.

XIII. Immunodeficiency Syndrome

A. Acquired Immunodeficiency Syndrome (AIDS)

1. AIDS is a viral disease caused by HIV, which destroys T cells, thereby increasing susceptibility to infection and malignancy (Fig. 62-6).

2. The syndrome is manifested clinically by opportunistic infections and unusual neoplasms.

3. AIDS is considered a chronic illness.

4. The disease has a long incubation period, sometimes 10 years or longer.

5. Manifestations may not appear until late in the infection.

B. Diagnosis and monitoring of the client with AIDS

1. Refer to Box 62-4 for tests used to evaluate the progression of HIV infection.

2. Refer to Box 62-5 for information used to diagnose AIDS.

C. High-risk groups

1. Heterosexual or homosexual contact with high-risk individuals

2. Intravenous drug abusers

3. Persons receiving blood products

4. Health care workers

5. Babies born to infected mothers

D. Assessment

1. Malaise, fever, anorexia, weight loss, influenza-like
symptoms
2. Lymphadenopathy for at least 3 months
3. Leukopenia
4. Diarrhea
5. Fatigue
6. Night sweats
7. Presence of opportunistic infections
8. Protozoan infections (*Pneumocystis jiroveci* pneumonia, a major source of mortality)
10. Fungal infections (candidiasis, histoplasmosis)
11. Viral infections (cytomegalovirus, herpes simplex)
12. Bacterial infections

**E. Interventions**

1. Provide respiratory support.
2. Administer oxygen and respiratory treatments as prescribed.
3. Provide psychosocial support and support services as needed.
5. Monitor for signs of infection and institute protective isolation precautions as necessary.
6. Prevent the spread of infection.
7. Initiate standard and other necessary precautions.
8. Provide comfort as necessary.
10. Provide adequate nutritional support as prescribed.

**F. Kaposi’s sarcoma**

1. Description: Skin lesions that occur primarily in individuals with a compromised immune system
2. Assessment
   a. Kaposi’s sarcoma is a slow-growing tumor that appears as raised, oblong, purplish, reddish-brown lesions; may be tender or nontender.
   b. Organ involvement includes the lymph nodes, airways or lungs, or any part of the gastrointestinal tract from the mouth to anus.
3. Interventions
   a. Maintain standard precautions.
   b. Provide protective isolation if the immune system is depressed.
c. Prepare the client for radiation therapy or chemotherapy as prescribed.
d. Administer immunotherapy, as prescribed, to stabilize the immune system.

XIV. Posttransplantation Immunodeficiency

A. Description
1. Secondary immunodeficiency is immunosuppression caused by therapeutic agents.
2. The client must take immunosuppressive agents for the rest of his or her life posttransplantation to decrease rejection of the transplanted organ or tissue.

B. Diagnosis and monitoring of posttransplantation clients
1. Check renal and hepatic function.
2. Monitor the complete cell count with differential to determine signs of infection.
3. Assess all body secretions periodically for blood.

C. High-risk clients
1. Clients with a history of malignancy or premalignancy have an increased susceptibility to malignancy if immunosuppressed.
2. Clients with recent infection or exposure to tuberculosis, herpes zoster, or chickenpox have a high risk for severe generalized disease when on immunosuppressive agents.

D. Assessment
1. Assess for signs of opportunistic infections.
2. Assess nutritional status.
3. Assess for signs of rejection (signs will depend on the organ or tissue transplant).

E. Interventions
1. Strict aseptic technique is necessary.
2. Provide teaching regarding asepsis and the signs of infection and rejection.
3. Institute protective isolation precautions as necessary.
4. Provide psychosocial support as needed.
5. Provide client teaching about immunosuppressants.
FIG. 62-1 Components of the immune system. Ig, Immunoglobulin.
FIG. 62-2 Interpretation of intradermal test results, based on the size of the wheal after 15 to 30 minutes.

- **Negative**: Wheal is less than 0.5 cm in diameter
- **Positive**: Wheal is 0.5 cm in diameter (1+)
- **Positive**: Wheal is 1.0 cm in diameter (2+)
- **Positive**: Wheal is 1.5 cm in diameter (3+)
- **Positive**: Wheal is 2.0 cm in diameter (4+)
Clinical manifestations of a systemic anaphylactic reaction.

**Box 62-1**

**Products That May Contain Natural Rubber Latex**

- ACE bandages (brown)
- Adhesive or elastic bandages
- Ambu bag
- Balloons

**FIG. 62-3** Clinical manifestations of a systemic anaphylactic reaction.
• Blood pressure cuff (tubing and bladder)
• Catheter leg bag straps
• Catheters
• Condoms
• Diaphragms
• Elastic pressure stockings
• Electrocardiographic pads
• Feminine hygiene pads
• Gloves
• Intravenous catheters, tubing, and rubber injection ports
• Nasogastric tubes
• Pads for crutches
• Prepackaged enema kits
• Rubber stoppers on medication vials
• Stethoscopes
• Syringes

Note: Health care agencies use as many nonlatex products as possible and have nonlatex supplies available for clients with a latex allergy.
The first time a person is exposed to an allergen (e.g., ragweed), B cells quickly produce an antibody called IgE. This antibody is found on mast cells, which are specialized immune cells. These IgE antibodies attach to mast cells, ready for the next exposure.

The next time the person is exposed to the allergen (e.g., ragweed), it binds to the IgE antibodies that are attached to the mast cells. This triggers the release of chemical mediators from the mast cell. The chemical mediators travel to different parts of the body and cause various symptoms:

- **GI system**: Cramping pain, diarrhea, nausea, vomiting
- **Intravascular compartment**: Anaphylactic shock
- **Respiratory system**: Asthma, rhinitis
- **Skin**: Angioedema, atopic dermatitis, urticaria, wheal-flare reaction
Box 62-2

Interventions for the Client with a Latex Allergy

- Ask the client about a known allergy to latex when performing the initial assessment.
- Identify risk factors for a latex allergy in the client.
- Use nonlatex gloves and all latex-safe supplies.
- Keep a latex-safe supply cart near the client’s room.
- Apply a cloth barrier to the client’s arm under a blood pressure cuff.
- Use latex-free syringes and medication containers (glass ampules) and latex-safe intravenous equipment.
- Instruct the client to wear a MedicAlert bracelet.
- Instruct the client about the importance of informing health care providers and local and paramedic ambulance companies about the allergy.

Box 62-3

Assessment and Stages of Lyme Disease

First Stage

- Symptoms can occur several days to months following the bite.
- A small red pimple develops that may spread into a ring-shaped rash; it may occur anywhere on the body.
- Ring-shaped rash may be large or small, or may not occur at all.
- Flu-like symptoms occur, such as headaches, stiff neck, muscle aches, and fatigue.

Second Stage

- This stage occurs several weeks following the bite.
- Joint pain occurs.
- Neurological complications occur.
- Cardiac complications occur.

Third Stage
- Large joints become involved.
- Arthritis progresses.

**FIG. 62-5** Erythema migrans of Lyme disease. (From Swartz, 2010.)

**FIG. 62-6** The life cycle of human immunodeficiency virus (HIV).

**Box 62-4**
Tests Used to Evaluate Progression of Human Immunodeficiency Virus (HIV) Infection

Complete Blood Cell Count

- WBC count (normal to decreased)
- Lymphopenia (< 30% of the normal number of WBCs)
- Thrombocytopenia (decreased platelet count)

Lymphocyte Screen

- Reduced CD4⁺/CD8⁺ T cell ratio
- CD4⁺ (helper) lymphocytes decreased
- CD8⁺ lymphocytes increased

Quantitative Immunoglobulin

- IgG level increased
- IgA level frequently increased

Chemistry Panel

- Lactate dehydrogenase level increased (all fractions)
- Serum albumin level decreased
- Total protein increased
- Cholesterol level decreased
- AST and ALT levels elevated

Anergy Panel

- Nonreactive (anergic) or poorly reactive to infectious agents or environmental materials (e.g., pokeweed, phytohemagglutinin mitogens and antigens, mumps, Candida)

Hepatitis B Surface Antigen Testing

- To detect the presence of hepatitis B

Blood Cultures

- To detect septicemia
Chest Radiography

- To detect *Pneumocystis jiroveci* infection or tuberculosis

*ALT*, Alanine aminotransferase; *AST*, aspartate aminotransferase; *Ig*, immunoglobulin; *WBC*, white blood cell.

**Box 62-5**

**Diagnostic Criteria for Acquired Immunodeficiency Syndrome (AIDS)**

- CD4+ T cell count drops below 200 cells/L
- Presence of a fungal, viral, protozoal, or bacterial infection
  - Candidiasis of bronchi, trachea, lungs, or esophagus
  - *Pneumocystis jiroveci* pneumonia
  - Disseminated or extrapulmonary coccidiomycosis
  - Disseminated or extrapulmonary histoplasmosis
  - Cytomegalovirus
  - Herpes simplex
  - Progressive multifocal leukoencephalopathy
  - Toxoplasmosis
  - *Mycobacterium tuberculosis*
  - Recurrent pneumonia
  - Recurrent *salmonella* septicemia
- Presence of an opportunistic cancer
  - Invasive cervical cancer
  - Kaposi’s sarcoma
  - Burkitt’s lymphoma
  - Immunoblastic lymphoma
  - Primary lymphoma of the brain
- Wasting syndrome (10% or more of ideal body mass)
- AIDS dementia complex

**Practice Questions**

763. The nurse prepares to give a bath and change the bed linens of a client with
cutaneous Kaposi’s sarcoma lesions. The lesions are open and draining a scant amount of serous fluid. Which would the nurse incorporate into the plan during the bathing of this client?
1. Wearing gloves
2. Wearing a gown and gloves
3. Wearing a gown, gloves, and a mask
4. Wearing a gown and gloves to change the bed linens, and gloves only for the bath

764. The nurse provides home care instructions to a client with systemic lupus erythematosus and tells the client about methods to manage fatigue. Which statement by the client indicates a need for further instruction?
1. “I should take hot baths because they are relaxing.”
2. “I should sit whenever possible to conserve my energy.”
3. “I should avoid long periods of rest because it causes joint stiffness.”
4. “I should do some exercises, such as walking, when I am not fatigued.”

765. A client develops an anaphylactic reaction after receiving morphine. The nurse should plan to institute which actions? Select all that apply.
1. Administer oxygen.
2. Quickly assess the client’s respiratory status.
3. Document the event, interventions, and client’s response.
4. Leave the client briefly to contact a primary health care provider (PHCP).
5. Keep the client supine regardless of the blood pressure readings.
6. Start an intravenous (IV) infusion of D5W and administer a 500-mL bolus.

766. The nurse is conducting a teaching session with a client on their diagnosis of pemphigus. Which statement by the client indicates that the client understands the diagnosis?
1. “My skin will have tiny red vesicles.”
2. “The presence of the skin vesicles is caused by a virus.”
3. “I have an autoimmune disease that causes blistering in the skin.”
4. “Red, raised papules and large plaques covered by silvery scales will be present on my skin.”

767. The nurse is assisting in planning care for a client with a diagnosis of immunodeficiency and should incorporate which action as a priority in the plan?
1. Protecting the client from infection
2. Providing emotional support to decrease fear
3. Encouraging discussion about lifestyle changes
4. Identifying factors that decreased the immune function

768. A client calls the nurse in the emergency department and states that he was
just stung by a bumblebee while gardening. The client is afraid of a severe reaction because the client’s neighbor experienced such a reaction just 1 week ago. Which action should the nurse take?

1. Advise the client to soak the site in hydrogen peroxide.
2. Ask the client if he ever sustained a bee sting in the past.
3. Tell the client to call an ambulance for transport to the emergency department.
4. Tell the client not to worry about the sting unless difficulty with breathing occurs.

769. The community health nurse is conducting a research study and is identifying clients in the community at risk for latex allergy. Which client population is most at risk for developing this type of allergy?

1. Hairdressers
2. The homeless
3. Children in day care centers
4. Individuals living in a group home

770. Which interventions apply in the care of a client at high risk for an allergic response to a latex allergy? Select all that apply.

1. Use nonlatex gloves.
2. Use medications from glass ampules.
3. Place the client in a private room only.
4. Keep a latex-safe supply cart available in the client’s area.
5. Avoid the use of medication vials that have rubber stoppers.
6. Use a blood pressure cuff from an electronic device only to measure the blood pressure.

771. A client presents at the primary health care provider’s office with complaints of a ring-like rash on his upper leg. Which question should the nurse ask first?

1. “Do you have any cats in your home?”
2. “Have you been camping in the last month?”
3. “Have you or close contacts had any flu-like symptoms within the last few weeks?”
4. “Have you been in physical contact with anyone who has the same type of rash?”

772. A client is diagnosed with scleroderma. Which intervention should the nurse anticipate to be prescribed?

1. Maintain bed rest as much as possible.
2. Administer corticosteroids as prescribed for inflammation.
3. Advise the client to remain supine for 1 to 2 hours after meals.
4. Keep the room temperature warm during the day and cool at night.

773. A client arrives at the health care clinic and tells the nurse that she was just bitten by a tick and would like to be tested for Lyme disease. The client tells the nurse that she removed the tick and flushed it down the toilet. Which
actions are most appropriate? Select all that apply.

☐ 1. Tell the client that testing is not necessary unless arthralgia develops.
☐ 2. Tell the client to avoid any woody, grassy areas that may contain ticks.
☐ 3. Instruct the client to immediately start to take the antibiotics that are prescribed.
☐ 4. Inform the client to plan to have a blood test 4 to 6 weeks after a bite to detect the presence of the disease.
☐ 5. Tell the client that if this happens again, to never remove the tick but vigorously scrub the area with an antiseptic.

774. The nurse is preparing a group of Cub Scouts for an overnight camping trip and instructs the Scouts about the methods to prevent Lyme disease. Which statement by one of the Scouts indicates a need for further instruction?
1. “I need to bring a hat to wear during the trip.”
2. “I should wear long-sleeved tops and long pants.”
3. “I should not use insect repellents because it will attract the ticks.”
4. “I need to wear closed shoes and socks that can be pulled up over my pants.”

775. The client with acquired immunodeficiency syndrome is diagnosed with cutaneous Kaposi’s sarcoma. Based on this diagnosis, the nurse understands that this has been confirmed by which finding?
1. Swelling in the genital area
2. Swelling in the lower extremities
3. Positive punch biopsy of the cutaneous lesions
4. Appearance of reddish-blue lesions noted on the skin

776. The nurse is conducting allergy skin testing on a client. Which postprocedure interventions are most appropriate? Select all that apply.

☐ 1. Record site, date, and time of the test.
☐ 2. Give the client a list of potential allergens if identified.
☐ 3. Estimate the size of the wheal and document the finding.
☐ 4. Tell the client to return to have the site inspected only if there is a reaction.
☐ 5. Have the client wait in the waiting room for at least 1 to 2 hours after injection.

777. The nurse is performing an assessment on a client who has been diagnosed with an allergy to latex. In determining the client’s risk factors, the nurse should question the client about an allergy to which food item?
1. Eggs
2. Milk
3. Yogurt
4. Bananas
Answers

763. **Answer: 2**

**Rationale:** Gowns and gloves are required if the nurse anticipates contact with soiled items such as those with wound drainage, or is caring for a client who is incontinent with diarrhea or a client who has an ileostomy or colostomy. Masks are not required unless droplet or airborne precautions are necessary. Regardless of the amount of wound drainage, a gown and gloves must be worn.

**Test-Taking Strategy:** Focus on the **subject**, the method of transmission of infection from Kaposi’s sarcoma. Read the question, noting the task that is presented; in this case, it is bathing and changing linens. Eliminate option 3, because the method of transmission is not respiratory. Eliminate options 1 and 4 because neither provides adequate protection based on the method of transmission.

**Level of Cognitive Ability:** Applying

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Planning

**Content Area:** Foundations of Care: Infection Control

**Health Problem:** Adult Health: Immune: Immunodeficiency Syndrome

**Priority Concepts:** Infection; Safety

764. **Answer: 1**

**Rationale:** To help reduce fatigue in the client with systemic lupus erythematous, the nurse should instruct the client to sit whenever possible, avoid hot baths (because they exacerbate fatigue), schedule moderate low-impact exercises when not fatigued, and maintain a balanced diet. The client is instructed to avoid long periods of rest because it promotes joint stiffness.

**Test-Taking Strategy:** Note the **strategic words**, need for further instruction. These words indicate a **negative event query** and the need to select the incorrect client statement. Also, focus on the **subject**, fatigue. This will assist in directing you to the correct option as the action that would exacerbate fatigue.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Adult Health: Immune

**Health Problem:** Adult Health: Immune: Autoimmune Disease

**Priority Concepts:** Client Education; Immunity

**Reference:** Lewis et al. (2017), p. 1542.

765. **Answer: 1, 2, 3**

**Rationale:** An anaphylactic reaction requires immediate action, starting with quickly assessing the client’s respiratory status. Although the PHCP and the Rapid Response Team must be notified immediately, the nurse must stay with the client.
Oxygen is administered and an IV of normal saline is started and infused per PHCP prescription. Documentation of the event, actions taken, and client outcomes needs to be performed. The head of the bed should be elevated if the client’s blood pressure is normal.

**Test-Taking Strategy:** Focus on the **subject**, interventions the nurse takes for an anaphylactic reaction. Read each option carefully and remember that this is an emergency. Think about the pathophysiology that occurs in this reaction to answer correctly.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Complex Care: Emergency Situations/Management  
**Health Problem:** Adult Health: Immune: Hypersensitivity Reactions and Allergy  
**Priority Concepts:** Clinical Judgment; Immunity  

766. **Answer:** 3

**Rationale:** Pemphigus is an autoimmune disease that causes blistering in the epidermis. The client has large flaccid blisters (bullae). Because the blisters are in the epidermis, they have a thin covering of skin and break easily, leaving large denuded areas of skin. On initial examination, clients may have crusting areas instead of intact blisters. Option 1 describes eczema, option 2 describes herpes zoster, and option 4 describes psoriasis.

**Test-Taking Strategy:** Focus on the **subject**, the characteristics of pemphigus. Think about the pathophysiology associated with this disorder and recall that pemphigus vulgaris is an autoimmune disorder.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Adult Health: Immune  
**Health Problem:** Adult Health: Immune: Autoimmune Disease  
**Priority Concepts:** Client Education; Immunity  

767. **Answer:** 1

**Rationale:** The client with immunodeficiency has inadequate or absence of immune bodies and is at risk for infection. The priority nursing intervention would be to protect the client from infection. Options 2, 3, and 4 may be components of care but are not the priority.

**Test-Taking Strategy:** Note the **strategic word**, **priority**. Use **Maslow’s Hierarchy of Needs theory** to answer the question. Remember that physiological needs are the priority. This will direct you to the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Planning
**Rationale:** In some types of allergies, a reaction occurs only on second and subsequent contacts with the allergen. The appropriate action, therefore, would be to ask the client if he ever experienced a bee sting in the past. Option 1 is not appropriate advice. Option 3 is unnecessary. The client should not be told “not to worry.”

**Test-Taking Strategy:** Use the steps of the nursing process to answer the question. The correct option is the only one that addresses assessment.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Adult Health: Immune

**Health Problem:** Adult Health: Immune: Hypersensitivity Reactions and Allergy

**Priority Concepts:** Clinical Judgment; Immunity

---

**Rationale:** Individuals most at risk for developing a latex allergy include health care workers; individuals who work in the rubber industry; or those who have had multiple surgeries, have spina bifida, wear gloves frequently (such as food handlers, hairdressers, and auto mechanics), or are allergic to kiwis, bananas, pineapples, tropical fruits, grapes, avocados, potatoes, hazelnuts, or water chestnuts.

**Test-Taking Strategy:** Focus on the subject, a latex allergy, and note the strategic word, most. Recalling the sources of latex and of the allergic reaction will direct you easily to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Health Promotion and Maintenance

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Immune

**Health Problem:** Adult Health: Immune: Hypersensitivity Reactions and Allergy

**Priority Concepts:** Health Promotion; Immunity

---

**Rationale:** If a client is allergic to latex and is at high risk for an allergic response, the nurse would use nonlatex gloves and latex-safe supplies, and would keep a latex-safe supply cart available in the client’s area. Any supplies or materials that contain latex would be avoided. These include blood pressure cuffs and medication vials with rubber stoppers that require puncture with a needle. It is not necessary to
place the client in a private room.

**Test-Taking Strategy:** Focus on the **subject**, the client at high risk for an allergic response to latex. Recalling that items that contain rubber are likely to contain latex will direct you to the correct interventions. Also, noting the **closed-ended word** “only” in options 3 and 6 will assist in eliminating these options.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Adult Health: Immune

**Health Problem:** Adult Health: Immune: Hypersensitivity Reactions and Allergy

**Priority Concepts:** Clinical Judgment; Immunity

**Reference:** Lewis et al. (2017), pp. 203-204.

771. **Answer:** 2

**Rationale:** The nurse should ask questions to assist in identifying a cause of Lyme disease, which is a multisystem infection that results from a bite by a tick carried by several species of deer. The rash from a tick bite can be a ring-like rash occurring 3 to 4 weeks after a bite and is commonly seen on the groin, buttocks, axillae, trunk, and upper arms or legs. Option 1 is referring to toxoplasmosis, which is caused by the inhalation of cysts from contaminated cat feces. Lyme disease cannot be transmitted from one person to another.

**Test-Taking Strategy:** Focus on the **strategic word**, first. Also focus on the **data in the question**. Eliminate options 3 and 4 because they are **comparable or alike**. It is important in the initial assessment for the nurse to determine the cause of the rash. If the client sustained a bite while out in the woods, Lyme disease should be suspected.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Adult Health: Immune

**Health Problem:** Adult Health: Immune: Lyme Disease

**Priority Concepts:** Clinical Judgment; Infection

**Reference:** Lewis et al. (2017), pp. 1534-1535.

772. **Answer:** 2

**Rationale:** Scleroderma is a chronic connective tissue disease similar to systemic lupus erythematosus. Corticosteroids may be prescribed to treat inflammation. Topical agents may provide some relief from joint pain. Activity is encouraged as tolerated, and the room temperature needs to be constant. Clients need to sit up for 1 to 2 hours after meals if esophageal involvement is present.

**Test-Taking Strategy:** Focus on the **subject**, scleroderma. Think about the pathophysiology associated with this condition and read each option carefully to assist in answering correctly.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Planning
**Rationale:** A blood test is available to detect Lyme disease; however, the test is not reliable if performed before 4 to 6 weeks following the tick bite. Antibody formation takes place in the following manner. Immunoglobulin M is detected 3 to 4 weeks after Lyme disease onset, peaks at 6 to 8 weeks, and then gradually disappears; immunoglobulin G is detected 2 to 3 months after infection and may remain elevated for years. Areas that ticks inhabit need to be avoided. Ticks should be removed with tweezers and then the area is washed with an antiseptic. Options 1 and 5 are incorrect.

**Test-Taking Strategy:** Focus on the subject, measures to take if Lyme disease is suspected. Also note the strategic words, most appropriate. Eliminate option 1, because treatment should begin before the arthralgia develops. Eliminate option 5, because ticks need to be removed.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Adult Health: Immune

**Health Problem:** Adult Health: Immune: Lyme Disease

**Priority Concepts:** Caregiving; Immunity

---

**Rationale:** In the prevention of Lyme disease, individuals need to be instructed to use an insect repellent on the skin and clothes when in an area where ticks are likely to be found. Long-sleeved tops and long pants, closed shoes, and a hat or cap should be worn. If possible, heavily wooded areas or areas with thick underbrush should be avoided. Socks can be pulled up and over the pant legs to prevent ticks from entering under clothing.

**Test-Taking Strategy:** Note the strategic words, need for further instruction. These words indicate a negative event query and ask you to select an option that is incorrect. Note that the correct option uses the words should not. Reading carefully will assist in directing you to this option.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Teaching and Learning

**Content Area:** Foundations of Care: Infection Control

**Health Problem:** Adult Health: Immune: Lyme Disease

**Priority Concepts:** Client Education; Infection

Rationale: Kaposi’s sarcoma lesions begin as red, dark blue, or purple macules on the lower legs that change into plaques. These large plaques ulcerate or open and drain. The lesions spread by metastasis through the upper body and then to the face and oral mucosa. They can move to the lymphatic system, lungs, and gastrointestinal tract. Late disease results in swelling and pain in the lower extremities, penis, scrotum, or face. Diagnosis is made by punch biopsy of cutaneous lesions and biopsy of pulmonary and gastrointestinal lesions.

Test-Taking Strategy: Focus on the subject, diagnosing Kaposi’s sarcoma. Eliminate options 1 and 2 first, because these symptoms occur late in the development of Kaposi’s sarcoma. Then, note the word confirmed in the question. This word will assist in directing you to the option that will confirm the diagnosis, the biopsy of the lesions.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Immune
Health Problem: Adult Health: Immune: Immunodeficiency Syndrome
Priority Concepts: Evidence; Immunity

Rationale: Skin testing involves administration of an allergen to the surface of the skin or into the dermis. Site, date, and time of the test must be recorded, and the client must return at a specific date and time for a follow-up site evaluation, even if no reaction is suspected. A list of potential allergens is identified and reviewed and given to the client. For the follow-up evaluation, the size of the site has to be measured and not estimated. After injection, clients only need to be monitored for about 30 minutes to assess for any adverse effects.

Test-Taking Strategy: Note the strategic words, most appropriate. Eliminate option 3, because any results must be accurately measured and not estimated. Eliminate option 4 because of the closed-ended word “only.” Eliminate option 5, because it is unreasonable to have the client wait 1 to 2 hours.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Adult Health: Immune
Health Problem: Adult Health: Immune: Hypersensitivity Reactions and Allergies
Priority Concepts: Client Education; Immunity
developing a latex allergy. This is thought to be the result of a possible cross-reaction between the food and the latex allergen. Options 1, 2, and 3 are unrelated to latex allergy.

**Test-Taking Strategy:** Recall knowledge regarding the food items related to a latex allergy. Eliminate options 1, 2, and 3 because they are comparable or alike and relate to dairy products.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Health Promotion and Maintenance  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Immune  
**Health Problem:** Adult Health: Immune: Immunodeficiency Syndrome  
**Priority Concepts:** Clinical Judgment; Immunity  
I. Human Immunodeficiency Virus (HIV) and Acquired Immunodeficiency Syndrome (AIDS)
   A. Medications include nucleoside-nucleotide reverse transcriptase inhibitors (NRTIs), nonnucleoside reverse transcriptase inhibitors (NNRTIs), protease inhibitors (PIs), and fusion inhibitors (Box 63-1).
   B. NRTIs and NNRTIs work by inhibiting the activity of reverse transcriptase.
   C. PIs work by interfering with the activity of the enzyme protease.
   D. Fusion inhibitors work by inhibiting the binding of HIV to cells.
   E. Standard treatment consists of using 3 or 4 medications in regimens known as highly active antiretroviral therapy (HAART); this therapy is not curative but can delay or reverse loss of immune function, preserve health, and prolong life.
   F. Other medications include those that are used to treat complications or opportunistic infections that develop (see Box 63-1).
   G. Nucleoside-nucleotide reverse transcriptase inhibitors (NRTIs)
      1. Abacavir: Can cause nausea; monitor for hypersensitivity reaction, including fever, nausea, vomiting, diarrhea, lethargy, malaise, sore throat, shortness of breath, cough, and rash
      2. Abacavir/lamivudine: In addition to the effects that can occur from abacavir and lamivudine, hypersensitivity reactions, lactic acidosis, and severe hepatomegaly can occur.
      3. Didanosine: Can cause nausea, diarrhea, peripheral neuropathy, hepatotoxicity, and pancreatitis
      4. Emtricitabine: Can cause headache, diarrhea, nausea, rash, hyperpigmentation of the palms and soles, lactic
acidosis, and severe hepatomegaly
5. Emtricitabine/tenofovir: In addition to the effects that can occur from emtricitabine and tenofovir (see later), lactic acidosis and severe hepatomegaly can occur.
6. Lamivudine: Causes nausea and nasal congestion
7. Lamivudine/zidovudine: Can cause anemia and neutropenia and lactic acidosis with hepatomegaly
8. Lamivudine/zidovudine/abacavir: In addition to the effects that can occur from lamivudine, zidovudine (see later), and abacavir, hypersensitivity reactions, anemia, neutropenia, lactic acidosis, and severe hepatomegaly can occur.
9. Stavudine: Can cause peripheral neuropathy and pancreatitis
10. Tenofovir: Can cause nausea and vomiting
11. Zidovudine: Can cause nausea, vomiting, anemia, leukopenia, myopathy, fatigue, and headache

H. Nonnucleoside reverse transcriptase inhibitors (NNRTIs)

1. Delavirdine: Can cause rash, liver function changes, and pruritus
2. Efavirenz: Can cause rash, dizziness, confusion, difficulty concentrating, dreams, and encephalopathy
3. Etravirine: Can cause rash, gastrointestinal disturbances, headache, hypertension, and peripheral neuropathy
4. Nevirapine: Can cause rash, Stevens-Johnson syndrome, hepatitis, and increased transaminase levels
5. Rilpivirine can cause headache, nausea, stomach pain, rash, dizziness, and feeling sleepy during the daytime.

I. Protease inhibitors (PIs)

1. Atazanavir: Can cause nausea, headache, infection, vomiting, diarrhea, drowsiness, insomnia, fever, hyperglycemia, hyperlipidemia, and increased bleeding in clients with hemophilia
2. Darunavir: Can cause diarrhea, nausea, vomiting, heartburn, stomach pain, headache, rash, changes in the shape and location of body fat
3. Fosamprenavir: Can cause nausea, vomiting, headache, altered taste sensations, perioral paresthesia, rashes, and altered liver function
4. Indinavir: Can cause nausea, diarrhea, hyperbilirubinemia, nephritis, and kidney stones
5. Lopinavir/ritonavir: Can cause nausea, diarrhea,
altered taste sensations, circumoral paresthesia, and hepatitis
6. Nelfinavir: Can cause nausea, flatulence, and diarrhea
7. Ritonavir: Can cause nausea, vomiting, diarrhea, altered taste sensations, circumoral paresthesia, hepatitis, and increased triglyceride levels
8. Saquinavir: Can cause nausea, diarrhea, photosensitivity, and headache
9. Tipranavir: Hepatotoxicity (liver damage); can also cause nausea, vomiting, diarrhea, headache, and fatigue

J. Integrase inhibitors
1. Stops HIV replication and is used in combination with other antiretroviral medications
2. Can cause nausea, diarrhea, fatigue, headache, and itching; hypersensitivity and liver problems (dolutegravir)

K. Fusion inhibitor: Enfuvirtide can cause skin irritation at injection site, fatigue, nausea, insomnia, and peripheral neuropathy.

L. Chemokine receptor 5 (CCR5) antagonist: Maraviroc
1. Binds with CCR5 and blocks viral entry
2. Can cause cough, dizziness, pyrexia, rash, abdominal pain, musculoskeletal symptoms, and upper respiratory tract infections; liver injury and cardiovascular events have occurred in some clients.

M. Antiinflammatory and antiinfective medications: Used to treat opportunistic infections such as Pneumocystis jiroveci pneumonia; Toxoplasma encephalitis is treated with sulfamethoxazole/trimethoprim (see Box 63-1).

N. Antifungal medications: Used to treat candidiasis and cryptococcal meningitis (see Box 63-1)

O. Antiviral medications: Used to treat cytomegalovirus retinitis, herpes simplex, and varicella-zoster virus (see Box 63-1)

II. Immunosuppressants (Box 63-2)
A. Description: Immunosuppressants are used for transplant recipients to prevent organ or tissue rejection and to treat
autoimmune disorders such as systemic lupus erythematosus.

B. Cyclosporine
   1. Used for prevention of rejection following allogeneic organ transplantation
   2. Usually administered with a glucocorticoid and another immunosuppressant
   3. The most common adverse effects are nephrotoxicity, infection, hypertension, and hirsutism.

C. Tacrolimus
   1. Used for prevention of rejection following liver or kidney transplantation
   2. Adverse effects include nephrotoxicity, neurotoxicity, gastrointestinal effects, hypertension, hyperkalemia, hyperglycemia, hirsutism, and gum hyperplasia.

D. Azathioprine
   1. Generally used with renal transplant recipients
   2. Can cause neutropenia and thrombocytopenia

E. Cyclophosphamide
   1. Used for its immunosuppressant action to treat autoimmune disorders
   2. Can cause neutropenia and hemorrhagic cystitis

F. Methotrexate
   1. Used for its immunosuppressant action to treat autoimmune disorders
   2. Can cause hepatic fibrosis and cirrhosis, bone marrow suppression, ulcerative stomatitis, and renal damage

G. Mycophenolate mofetil and mycophenolic acid
   1. Used to prevent rejection following kidney, heart, and liver transplantation
   2. Can cause diarrhea, vomiting, neutropenia, and sepsis; increases the risk of infection and malignancies, especially lymphomas

H. Basiliximab
   1. Used to prevent rejection following kidney transplantation
   2. Can cause severe acute hypersensitivity reactions, including anaphylaxis

I. Lymphocyte immune globulin, antithymocyte globulin, muromonab CD3
   1. Used to prevent rejection following kidney, heart, liver, and bone marrow transplantation
   2. Side and adverse effects include fever, chills, leukopenia, and skin reactions.
   3. Can cause anaphylactoid reactions

J. Sirolimus
   1. Used to prevent renal transplant rejection
   2. Increases the risk of infection; raises cholesterol and triglyceride levels; can cause renal injury
3. Can cause rash, acne, anemia, thrombocytopenia, joint pain, diarrhea, and hypokalemia.
4. Everolimus can cause mouth sores, infections, swelling and edema

Monitor the client taking an immunosuppressant closely for signs of infection.

III. Immunizations: See Chapter 18 for more information

IV. Antimicrobials (Box 63-3)
   A. Inhibit the growth of bacteria
   B. Include medication classifications of aminoglycosides, cephalosporins, fluoroquinolones, macrolides, lincosamides, monobactams, penicillins and penicillinase-resistant penicillins, sulfonamides, streptogramins, tetracyclines, antimycobacterials, and others (see Box 63-3)
   C. Adverse effects (Table 63-1)
   D. Nursing considerations
      1. Assess for allergies.
      2. Monitor appropriate laboratory values before therapy as appropriate and during therapy to assess for adverse effects.
      3. Report adverse effects to the primary health care provider if any occur.
      4. Determine the appropriate method of administration and provide instructions to the client.
      5. Monitor intake and output.
      7. Initiate safety precautions because of possible central nervous system effects.
      8. Teach the client about the medication and how to take it; emphasize the importance of completing the full prescribed course.

---

**Box 63-1**

**Medications for Human Immunodeficiency Virus (HIV) and Acquired Immunodeficiency Syndrome (AIDS)**

**Nucleoside-Nucleotide Reverse Transcriptase Inhibitors (NRTIs)**

- Abacavir
- Abacavir/lamivudine
• Didanosine
• Emtricitabine
• Emtricitabine/tenofovir
• Lamivudine
• Lamivudine/zidovudine
• Lamivudine/zidovudine/abacavir
• Stavudine
• Tenofovir
• Zidovudine

Nonnucleoside Reverse Transcriptase Inhibitors (NNRTIs)

• Delavirdine
• Efavirenz
• Etravirine
• Nevirapine
• Rilpivirine

Protease Inhibitors (PIs)

• Atazanavir
• Darunavir
• Fosamprenavir
• Indinavir
• Lopinavir/ritonavir
• Nelfinavir
• Ritonavir
• Saquinavir
• Tipranavir

Integrase Inhibitor

• Raltegravir
• Dolutegravir
• Elvitegravir

Fusion Inhibitor

• Enfuvirtide

Chemokine Receptor 5 (CCR5) Antagonist
- Maraviroc

**Antiinflammatory Medication**

- Sulfasalazine

**Antiinfective Medications**

- Atovaquone
- Metronidazole
- Pentamidine isethionate
- Sulfamethoxazole/trimethoprim

**Antifungal Medications**

- Amphotericin B
- Fluconazole
- Itraconazole
- Ketoconazole
- Voriconazole

**Antiviral Medications**

- Acyclovir
- Foscarnet
- Ganciclovir
- Valacyclovir

---

**Box 63-2**

**Immunosuppressants**

**Calcineurin Inhibitors**

- Cyclosporine
- Tacrolimus

**Cytotoxic Medications**

- Azathioprine
- Cyclophosphamide
- Methotrexate
- Mycophenolate mofetil
- Mycophenolic acid

**Antibodies**
- Basiliximab
- Lymphocyte immune globulin, antithymocyte globulin, Muromonab-CD3

**Other**
- Sirolimus
- Everolimus

**Glucocorticoids**
- See Chapter 47

---

**Box 63-3**

**Antimicrobials**

**Aminoglycosides**
- Amikacin
- Gentamicin
- Neomycin
- Streptomycin
- Tobramycin

**Cephalosporins**
- Cefaclor
- Cefadroxil
- Cefazolin
- Cefdinir
- Cefditoren
- Cefepime
- Cefixime
- Cefotaxime
- Cefotetan
- Cefoxitin
- Cefpodoxime
• Cefprozil
• Ceftazidime
• Ceftibuten
• Ceftriaxone
• Cefuroxime
• Cephalexin

**Fluoroquinolones**

• Ciprofloxacin
• Gemifloxacin
• Levofloxacin
• Moxifloxacin
• Ofloxacin

**Macrolides**

• Azithromycin
• Clarithromycin
• Erythromycin
• Fidaxomicin

**Lincosamides**

• Clindamycin
• Lincomycin

**Monobactam**

• Aztreonam

**Penicillins**

• Amoxicillin
• Ampicillin
• Penicillin G
• Penicillin V
• Piperacillin

**Penicillinase-Resistant Penicillins**

• Dicloxacillin
- Nafcillin
- Oxacillin

**Sulfonamides**

- Sulfamethoxazole
- Sulfadiazine
- Sulfasalazine
- Sulfisoxazole
- Trimethoprim/sulfamethoxazole

**Streptogramins**

- Quinupristin/dalfopristin

**Tetracyclines**

- Demeclocycline
- Doxycycline
- Minocycline
- Tetracycline

**Antimycobacterials**

- Antituberculosis agents (see Chapter 51)
- Leprostatics: Clofazimine, Thalidomide

**Antifungal Medications**

- Amphotericin B
- Fluconazole
- Itraconazole
- Ketoconazole
- Posaconazole
- Voriconazole

**Antiviral Medications**

- Acyclovir
- Famciclovir
- Foscarnet
- Ganciclovir

### Practice Questions

778. The client with acquired immunodeficiency syndrome and *Pneumocystis jiroveci* infection has been receiving pentamidine. The client develops a temperature of 101°F (38.3°C). The nurse continues to assess the client,
knowing that this sign most likely indicates which condition?
1. That the dose of the medication is too low
2. That the client is experiencing toxic effects of the medication
3. That the client has developed inadequacy of thermoregulation
4. That the client has developed another infection caused by leukopenic effects of the medication

779. The nurse caring for a client who is taking an aminoglycoside should monitor the client for which adverse effects of the medication? Select all that apply.

- [ ] 1. Seizures
- [ ] 2. Ototoxicity
- [ ] 3. Renal toxicity
- [ ] 4. Dysrhythmias
- [ ] 5. Hepatotoxicity

780. Ketoconazole is prescribed for a client with a diagnosis of candidiasis. Which interventions should the nurse include when administering this medication? Select all that apply.

- [ ] 1. Restrict fluid intake.
- [ ] 2. Monitor liver function studies.
- [ ] 3. Instruct the client to avoid alcohol.
- [ ] 4. Administer the medication with an antacid.
- [ ] 5. Instruct the client to avoid exposure to the sun.
- [ ] 6. Administer the medication on an empty stomach.

781. The nurse is caring for a client who has been taking a sulfonamide and should monitor for signs and symptoms of which adverse effects of the medication? Select all that apply.

- [ ] 1. Ototoxicity
- [ ] 2. Palpitations
- [ ] 3. Nephrotoxicity
- [ ] 4. Bone marrow suppression
- [ ] 5. Gastrointestinal (GI) effects
- [ ] 6. Increased white blood cell (WBC) count

782. The nurse is reviewing the results of serum laboratory studies drawn on a client with acquired immunodeficiency syndrome who is receiving didanosine. The nurse interprets that the client may have the medication discontinued by the health care provider if which elevated result is noted?

1. Serum protein level
2. Blood glucose level
3. Serum amylase level
4. Serum creatinine level

783. The nurse is caring for a postrenal transplantation client taking cyclosporine. The nurse notes an increase in one of the client’s vital signs, and the client is complaining of a headache. What vital sign is most likely increased?
   1. Pulse
   2. Respiration
   3. Blood pressure
   4. Pulse oximetry

784. Amikacin is prescribed for a client with a bacterial infection. The nurse instructs the client to contact the primary health care provider (PHCP) immediately if which occurs?
   1. Nausea
   2. Lethargy
   3. Hearing loss
   4. Muscle aches

785. The nurse is assigned to care for a client with cytomegalovirus retinitis and acquired immunodeficiency syndrome who is receiving foscarnet, an antiviral medication. The nurse should monitor the results of which laboratory study while the client is taking this medication?
   1. CD4+ T cell count
   2. Lymphocyte count
   3. Serum albumin level
   4. Serum creatinine level

786. A client who is human immunodeficiency virus seropositive has been taking stavudine. The nurse should monitor which most closely while the client is taking this medication?
   1. Gait
   2. Appetite
   3. Level of consciousness
   4. Gastrointestinal function

Answers

778. Answer: 4

Rationale: Frequent adverse effects of this medication include leukopenia, thrombocytopenia, and anemia. The client should be monitored routinely for signs and symptoms of infection. Options 1, 2, and 3 are inaccurate interpretations.

Test-Taking Strategy: Note the strategic words, most likely. Focus on the data in the question. Noting that the temperature is elevated will direct you to the correct option.

Level of Cognitive Ability: Synthesizing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Analysis
Content Area: Pharmacology: Immune Medications: Antimycobacterials
**Health Problem:** Adult Health: Respiratory: Viral, Bacterial, Fungal Infections  
**Priority Concepts:** Infection; Immunity  
**Reference:** Lilley et al. (2017), pp. 686-687, 690.

779. **Answer:** 2, 3, 4

**Rationale:** Aminoglycosides are administered to inhibit the growth of bacteria. Adverse effects of this medication include confusion, ototoxicity, renal toxicity, gastrointestinal irritation, palpitations or dysrhythmias, blood pressure changes, and hypersensitivity reactions. Therefore, the remaining options are incorrect.

**Test-Taking Strategy:** Focus on the subject, adverse effects of aminoglycosides. It is necessary to know the adverse effects associated with this medication to answer correctly. Remember that ototoxicity, renal toxicity, and dysrhythmias are adverse effects.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Immune Medications: Aminoglycosides  
**Health Problem:** Adult Health: Immune: Infections  
**Priority Concepts:** Clinical Judgment; Immunity  
**Reference:** Lilley et al. (2017), pp. 624-626.

780. **Answer:** 2, 3, 5

**Rationale:** Ketoconazole is an antifungal medication. There is no reason for the client to restrict fluid intake; in fact, this could be harmful to the client. The medication is hepatotoxic, and the nurse monitors liver function. It is administered with food (not on an empty stomach), and antacids are avoided for 2 hours after taking the medication to ensure absorption. The client is also instructed to avoid alcohol. In addition, the client is instructed to avoid exposure to the sun, because the medication increases photosensitivity.

**Test-Taking Strategy:** Focus on the subject, administration procedures, and recall that ketoconazole is an antifungal medication. Next, use general medication guidelines to select the correct interventions. Also, remember that this medication is administered with food and that it is hepatotoxic.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Pharmacology: Immune Medications: Antifungals  
**Health Problem:** Adult Health: Immune: Infections  
**Priority Concepts:** Clinical Judgment; Immunity  

781. **Answer:** 3, 4, 5

**Rationale:** Adverse effects of sulfonamides include nephrotoxicity, bone marrow suppression, GI effects, hepatotoxicity, dermatological effects, and some
neurological symptoms including headache, dizziness, vertigo, ataxia, depression, and seizures. Options 1, 2, and 6 are unrelated to these medications.

**Test-Taking Strategy:** Focus on the subject, adverse effects of sulfonamides. It is necessary to know the adverse effects associated with these medications to answer correctly. Remember that nephrotoxicity, bone marrow suppression, and GI symptoms are adverse effects of sulfonamides.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Immune Medications: Sulfonamides  
**Health Problem:** Adult Health: Immune: Infections  
**Priority Concepts:** Clinical Judgment; Immunity  

782. Answer: 3

**Rationale:** Didanosine can cause pancreatitis. A serum amylase level that is increased to 1.5 to 2 times normal may signify pancreatitis in the client with acquired immunodeficiency syndrome and is potentially fatal. The medication may have to be discontinued. The medication is also hepatotoxic and can result in liver failure.

**Test-Taking Strategy:** Focus on the subject, adverse effects of didanosine. Recalling that this medication can cause damage to the pancreas and is hepatotoxic will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Immune Medications: Antivirals  
**Health Problem:** Adult Health: Immune: Immunodeficiency Syndrome  
**Priority Concepts:** Clinical Judgment; Safety  

783. Answer: 3

**Rationale:** Hypertension can occur in a client taking cyclosporine, and because this client is also complaining of a headache, the blood pressure is the vital sign to be monitored most closely. Other adverse effects include infection, nephrotoxicity, and hirsutism. Options 1, 2, and 4 are unrelated to the use of this medication.

**Test-Taking Strategy:** Note the strategic words, most likely. Focus on the name of the medication and recall that this medication can cause hypertension. Also, noting that the client has a headache will assist you in answering correctly.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Immune Medications: Immunosuppressants  
**Health Problem:** Adult Health: Immune: Transplantation  
**Priority Concepts:** Clinical Judgment; Immunity  
**Reference:** Lewis et al. (2017), pp. 209, 211.
**Rationale:** Amikacin is an aminoglycoside. Adverse effects of aminoglycosides include ototoxicity (hearing problems), confusion, disorientation, gastrointestinal irritation, palpitations, blood pressure changes, nephrotoxicity, and hypersensitivity. The nurse instructs the client to report hearing loss to the PHCP immediately. Lethargy and muscle aches are not associated with the use of this medication. It is not necessary to contact the PHCP immediately if nausea occurs. If nausea persists or results in vomiting, the PHCP should be notified.

**Test-Taking Strategy:** Note the strategic word, immediately. Recalling that this medication is an aminoglycoside (most aminoglycoside medication names end in -cin) and that aminoglycosides are ototoxic will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Immune Medications: Aminoglycosides

**Health Problem:** Adult Health: Immune: Infections

**Priority Concepts:** Client Education; Safety

---

**Rationale:** Foscarnet is toxic to the kidneys. The serum creatinine level is monitored before therapy, two or three times per week during induction therapy, and at least weekly during maintenance therapy. Foscarnet also may cause decreased levels of calcium, magnesium, phosphorus, and potassium. Thus, these levels also are measured with the same frequency.

**Test-Taking Strategy:** Focus on the subject, the laboratory value to be monitored. Recalling that this medication is nephrotoxic will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Pharmacology: Immune Medications: Antivirals

**Health Problem:** Adult Health: Immune: Immunodeficiency Syndrome

**Priority Concepts:** Clinical Judgment; Safety

---

**Rationale:** Stavudine is an antiretroviral used to manage human immunodeficiency virus infection in clients who do not respond to or who cannot tolerate conventional therapy. The medication can cause peripheral neuropathy, and the nurse should monitor the client’s gait closely and ask the client about paresthesia. Options 2, 3, and 4 are unrelated to this medication.

**Test-Taking Strategy:** Note the strategic word, most. Focus on the name of the medication. Recalling that this medication causes peripheral neuropathy will direct you to the correct option.
Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Pharmacology: Immune Medications: Antivirals
Health Problem: Adult Health: Immune: Immunodeficiency Syndrome

UNIT XVIII
Mental Health Problems of the Adult Client
**Introduction**

### Pyramid to Success

The Pyramid to Success focuses on the therapeutic nurse–client relationship, client rights, the ethical and legal issues related to the care of a client with a mental health problem, and grief and loss. Pyramid Points also focus on the use of restraints (security devices), seclusion, and electroconvulsive therapy. Care for a client with an addiction, such as an eating disorder, substance abuse disorder, or gambling disorder, is another focus area. Additional areas of focus include anxiety, depression, suicide, abuse and neglect, violence, rape crisis interventions, post-traumatic stress disorders, obsessive-compulsive disorders, schizophrenia, and bipolar disorders. Pyramid Points also address the use of medications prescribed for a client with a mental health problem.

### Client Needs: Learning Objectives

#### Safe and Effective Care Environment

- Ensuring client advocacy
- Ensuring that informed consent related to treatments, such as restraints (security devices), seclusion, and electroconvulsive therapy, has been obtained
- Implementing legal responsibilities related to reporting incidences of abuse, neglect, or violence
- Maintaining confidentiality
- Providing psychiatric consultations and other interprofessional referrals
- Providing safety to the client and others
- Upholding client rights
- Using restraints (security devices) and seclusion appropriately and safely

#### Health Promotion and Maintenance

- Identifying community resources for the client
- Identifying individual lifestyle choices
- Performing psychosocial assessment techniques
- Providing health promotion programs related to addictions

#### Psychosocial Integrity

2221
Addressing grief and loss issues
Assessing for abuse and neglect situations
Assessing for addictions
Assessing for domestic violence
Caring for the client who has been sexually abused or raped
Considering religious, cultural, and spiritual influences on health
Developing a therapeutic nurse–client relationship
Identifying coping mechanisms
Identifying support systems
Implementing behavioral interventions
Providing crisis intervention
Providing a therapeutic milieu
Teaching stress-management techniques

Physiological Integrity

Assessing for abusive and self-destructive behavior
Monitoring elimination patterns
Monitoring for alterations in body systems related to substance abuse
Monitoring for expected and untoward effects of medications
Monitoring for potential complications related to medications and treatments, such as electroconvulsive therapy
Monitoring laboratory values related to medication therapy
Monitoring rest and sleep patterns
Providing adequate nutrition
Providing personal hygiene measures
CHAPTER 64

Foundations of Mental Health Nursing

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Caregiving; Coping

I. Nurse–Client Relationship

A. Principles

1. Genuineness, respect, and empathic understanding are characteristics important to the development of a therapeutic nurse–client relationship.
2. The client should be cared for in a holistic manner.
3. The nurse considers the client’s cultural and spiritual beliefs and values in assessing the client’s response to the nurse–client relationship and her or his adaptation to stressors.
4. Appropriate limits and boundaries define and facilitate a therapeutic nurse–client relationship.
5. Honest and open communication is important for the development of trust, an underpinning of the therapeutic nurse–client relationship.
6. The nurse uses therapeutic communication techniques to encourage the client to express thoughts and feelings as they address identified problem areas.
7. The nurse respects the client’s confidentiality and limits discussion of the client to the interprofessional health care team.
8. The goal of the nurse–client relationship is to assist the client to develop problem-solving abilities and coping mechanisms.

The nurse needs to consider the cultural, religious, and spiritual practices of the client and whether these practices may give the client hope, comfort, and support while healing.

B. Phases of a therapeutic nurse–client relationship

1. Preinteraction phase
   a. Begins before the nurse’s first contact

2223
with the client
b. Develops appropriate physical and interpersonal environment (seating, lighting) to promote comfort and facilitate collaboration
c. Anticipates potential client issues
d. Prepares for the client interaction
e. Determines how to initially approach client
f. The nurse should identify her or his own preconceived ideas, stereotypes, biases, and values that may impinge on the nurse–client relationship.

2. Orientation or introductory phase
   a. Acceptance, rapport, trust, and boundaries are established.
   b. Introduces herself or himself to the client by using first and last name and designation
   c. Identifies purpose and the time frame of the relationship (establishing a contract).
   d. Identifies client’s strengths and needs
e. Collects data and forms basis for diagnosis and client-centered goals.
f. Termination and separation of the relationship are discussed in anticipation of the time-limited nature of the relationship.

3. Working phase
   a. Exploring, focusing on, and evaluating the client’s concerns and problems occur; an attitude of acceptance and active listening assists the client to express thoughts and feelings.
   b. Actively problem solves with the client
   c. Uses interpersonal strategies to help the client identify effective coping strategies
d. Encourages self-direction and self-management whenever possible to promote health and wellness.

4. Termination or separation phase
   a. Prepares the client for termination and separation on initial
contact.
b. Evaluates progress and achievement of goals.
c. Identifies responses related to termination and separation, such as anger, distancing from the relationship, a return of symptoms, and dependency.
d. Encourages the client to express feelings about termination.
e. Identifies the client’s strengths and anticipated needs for follow-up care.
f. Refers the client to community resources and other support systems.

C. Family as an extension of the client

1. Family members should be viewed as collaborators in the management of a client’s mental health needs (maintain confidentiality as necessary).
2. Competence and caring focused toward family members enhance the nurse’s ability to identify client and family needs and to select and implement effective interventions directed toward promoting adaptive functioning.
3. Nurses have a professional obligation to be aware of and sensitive to the cultural, ethnic, religious, and spiritual factors that affect the structure and resulting needs of the client and her or his family.
4. Educating family members regarding the client’s mental health problem, identification of symptoms, and effective management of maladaptive behaviors plays a vital role in the client’s quality of life.

D. Impact of culture, ethnicity, religion, and spirituality on client care

1. Cultural competency allows the nurse to recognize the uniqueness of each client and the impact that culture, values, and religious and spiritual beliefs have on an individual’s mental health as well as the treatment required for existing mental health problem.
2. A client’s culture, ethnicity, values, and religious and spiritual belief systems can affect all aspects of mental health care, including medication therapies, and can act as either protective or risk factors when dealing with the development and/or treatment of mental health problems.
3. Nurses must be aware of the impact that their own
culture, religious and spiritual beliefs, and values have on the care they provide and to avoid biases.
4. The treatment plan must be agreed upon by both client and nurse and take into consideration the needs of the client whenever possible.

II. Therapeutic Communication Process

A. Principles
   1. Communication includes verbal and nonverbal expression (Fig. 64-1).
   2. Successful communication includes appropriateness, efficiency, flexibility, and feedback.
   3. Anxiety in the nurse or client impedes communication.
   4. Communication needs to be goal-directed within a professional framework.

B. Therapeutic and nontherapeutic communication techniques (Table 64-1)

III. Mental Health

A. Mental health is a lifelong process of successful adaptation to changing internal and external environments.
B. A mentally healthy individual is in contact with reality, can relate to people and situations in their environment, and can resolve conflicts within a problem-solving framework.
C. A mentally healthy individual has psychobiological resilience.

IV. Mental Health Problem

A. Description
   1. A mental health problem can cause the loss of the ability to respond to the internal and external environment in ways that are in harmony with oneself or the expectations of society.
   2. It is characterized by thought or behavior patterns that impair functioning and cause distress.

B. Personality characteristics
   1. Self-concept is distorted.
   2. Perception of strengths and weaknesses is unrealistic.
   3. Thoughts and perceptions may not be reality-based.
   4. The ability to find meaning and purpose in life may be impaired.
   5. Life direction and productivity may be disturbed.
   6. Meeting one’s own needs may be problematic.
   7. Excessive reliance or preoccupation on the thoughts, opinions, and actions of self or others may be present.

C. Adaptations to stress
   1. The individual’s sense of self-control may be affected.
   2. Perception of the environment may be distorted.
   3. Coping mechanisms may not exist or may be ineffective.

D. Interpersonal relationships
1. Interpersonal relationships may be minimally existent or may be negatively affected.

2. The ability to enjoy sustained intimacy in relationships is impaired.

V. Coping and Defense Mechanisms

A. Coping mechanisms

1. Coping involves any effort to decrease anxiety.

2. Coping mechanisms can be constructive or destructive, task- or problem-oriented in relation to direct problem solving, cognitively oriented in an attempt to neutralize the meaning of the problem, or defense- or emotion-oriented, thus regulating the response to protect oneself.

B. Defense mechanisms

1. As anxiety increases, the individual copes by using defense mechanisms.

2. A defense mechanism is a coping mechanism used in an effort to protect the individual from feelings of anxiety; as anxiety increases and becomes overwhelming, the individual copes by using defense mechanisms to protect the ego and decrease anxiety (Box 64-1)

C. Interventions

1. Assist the client to identify the source of anxiety and to explore methods to reduce anxiety.

2. Assess the client’s use of defense mechanisms.

3. Facilitate appropriate use of defense mechanisms.

4. Determine whether the defense mechanisms used by the client are effective for her or him or create additional distress.

5. Avoid arguing or criticizing the client’s behavior and the use of defense mechanisms.

6. Do not take defense coping mechanism away until client has established more appropriate coping strategies to effectively deal with stressors.

VI. Diagnostic and Statistical Manual of Mental Health Disorders

A. The Diagnostic and Statistical Manual of Mental Health Disorders, published by the American Psychiatric Association, provides guidelines for health care personnel for identifying and
categorizing mental health problems.
B. The manual is a system used in clinical, research, and educational settings, in which diagnostic criteria are included for each mental health problem.
C. The manual addresses culturally diverse populations and mental health problems that may be associated with a particular culture.
D. Dual diagnosis: Refers to the client who has both a mental health problem and a substance related problem simultaneously; also known as comorbidity or co-occurring problems

VII. Types of Mental Health Admissions and Discharges
A. Voluntary admission
  1. The client (or the client’s guardian) seeks admission for care.
  2. The voluntary client is free to sign out of the hospital with psychiatrist (primary health care provider [PHCP]) notification and prescription.
  3. Detaining a voluntary client against her or his will is termed false imprisonment.
  4. The client retains full civil rights (Box 64-2).

B. Right to confidentiality
  1. A client has a right to confidentiality of her or his medical information; the Health Insurance Portability and Accountability Act (HIPAA) of 1996 ensures client confidentiality with regard to the release and electronic transmission of data.
  2. Information sometimes must be released in life-threatening situations without the client’s consent.
  3. In the event of a specific threat against an identified individual, the health care professional has a legal obligation to warn the intended victim of a client’s threats of harm.

Except in an emergency situation, client information can be released only with the client’s informed consent, which specifies the information that can be released and the time frame for which the release is valid.

C. Involuntary admission
  1. Involuntary admission may be necessary when a person is mentally ill, is a danger to self or others, or is in need of mental health treatment or physical care.
  2. Involuntary admission occurs when a person is admitted or detained involuntarily for mental health
treatment because of actual or imminent danger to self or others; the person’s condition is deteriorating and they require hospitalization.

3. A client who is admitted involuntarily retains her or his right for informed consent.

4. The client retains the right to refuse treatments, including medications, unless a separate and specific treatment order is obtained from the court.

5. The client loses the right to refuse treatment when she or he poses an immediate danger to self or others, requiring immediate action by the interprofessional health care team.

6. Depending on the jurisdiction, an order from an external board such as a court or from the psychiatrist or PHCP is required for involuntary admissions except in the case of emergency, which allows time to obtain the necessary order from the board; in the case of all involuntary admissions, legal counsel must be provided for the client. In this situation, the client may be held for a 72-hour period until further evaluation is completed.

7. A hearing is held by an external board within a specified time period for a client admitted involuntarily; the specific time period varies by state. The psychiatrist or PHCP may also be the person making decisions surrounding client discourse, depending on location.

8. In most states, a client can institute a hearing to seek an expedient judicial discharge (a writ of habeas corpus).

9. At the hearing, a determination is made as to whether the client may be released from the hospital or detained for further treatment and evaluation, or committed to a mental health facility for an undetermined period.

10. A client has the right to treatment in the least restrictive treatment environment; if treatment objectives can be achieved by court-ordered treatment to an outpatient facility as opposed to an inpatient facility, the client has the right to be treated in the outpatient setting.

11. A client is considered legally competent unless she or he has been declared incompetent through a legal hearing separate from the involuntary commitment hearing.

12. In the course of providing nursing care and carrying out medical prescriptions, if the nurse
believes that a client lacks competency to make informed decisions, action should be initiated to determine whether a legal guardian or substitute decision-maker needs to be appointed by the court.

D. Release from the hospital
  1. Description
    a. In some, but not all, jurisdictions, a client may be released voluntarily, against medical advice, or with conditions (conditional release). It is important to be familiar with the laws in the area in which you work regarding conditional release.
    b. A client who has sought voluntary admission has the right to receive release upon request.
  2. Voluntary release
    a. In the absence of an act of self-harm or danger to others, a voluntary client should never be detained.
    b. If a voluntary client wishes to be discharged from treatment, but is considered potentially dangerous to self or others, the PHCP can order the client to be detained while legal proceedings for involuntary status are sought. In other areas, the PHCP places them on a 72-hour hold while further evaluation occurs.
    c. Some states provide for conditional release of involuntarily hospitalized clients; this enables the treating PHCP to prescribe continued treatment on an outpatient basis as opposed to discharging the client to follow up on her or his own initiative. Community treatment orders may also be instituted depending on the facility and on the area.
    d. Conditional release usually involves outpatient treatment for a specified period to determine the client’s compliance with medication protocol, ability to meet basic needs, and ability to reintegrate into the community.
e. An involuntary client who is released conditionally may be reinstitutionalized while the commitment is still in effect without recommencement of formal admission procedures.

3. Discharge planning and follow-up care
   a. Discharge is the termination of the client–institution relationship.
   b. The release may be prescribed by the psychiatrist, external board, or administration for involuntarily admitted clients and may be requested by voluntary clients at any time.
   c. In most states, the client can institute an external board hearing to seek an expedient judicial discharge (writ of habeas corpus).
   d. Discharge planning and follow-up care are important for the continued well-being of the client with a mental health problem.
   e. Aftercare case managers are used to facilitate the client’s adaptation back into the community and to provide early referral if the treatment plan is unsuccessful.

VIII. Types of Therapy for Care
   A. Milieu therapy
   1. The milieu refers to the safe physical and social environment in which an individual is receiving treatment.
   2. Safety is the most important priority in managing the milieu, and all encounters with the client have the goal of being “therapeutic.”
   3. All members of the interprofessional health care team contribute to the planning and functioning of the milieu and are significant and valuable to the client’s successful treatment outcomes; the team generally includes a registered nurse, social worker, exercise therapist, recreational therapist, psychologist, psychiatrist, occupational therapist, and clinical nurse specialist or nurse practitioner.
   4. Community meetings, activity groups, social skills groups, and physical exercise programs are included
to accomplish treatment goals.
5. One-to-one relationships are used to examine client behaviors, feelings, and interactions within the context of the therapeutic group activities.

The focus of milieu therapy is to empower the client through involvement in setting her or his own goals and to develop purposeful relationships with the staff to assist in meeting these goals.

B. Interpersonal psychotherapy
1. A treatment modality that uses a therapeutic relationship to modify the client’s feelings, attitudes, and behaviors and work within an agreed-upon time frame to help meet the client’s goals.
2. Therapeutic communication forms the foundation of the therapist–client relationship, and this relationship is used as a way for the client to examine other relationships in her or his life.
3. Supportive level of psychotherapy
   a. Brief therapy or may extend over a period of years, allowing the client to express feelings, explore alternatives, and make decisions in a safe, caring environment.
   b. No plan exists to introduce new methods of coping; instead, the therapist reinforces the client’s existing coping mechanisms.
4. Re-educative level of psychotherapy
   a. The client explores alternatives in a planned, systematic way; this requires a longer period of therapy than supportive therapy.
   b. The client agrees upon and specifies desired changes of behavior and learning new ways of perceiving and behaving.
   c. Techniques may include short-term psychotherapy, reality therapy, cognitive restructuring, behavior modification, and development of coping skills.
5. Reconstructive level of psychotherapy
   a. Emotional and cognitive restructuring of self takes place.
   b. Positive outcomes include a
greater understanding of self and others, more emotional freedom, and the development of potential abilities.

C. Behavior therapy
1. A treatment approach that uses the principles of Skinnerian (operant conditioning) or Pavlovian (classical conditioning) behavior theory to bring about behavioral change; the belief is that most behaviors are learned.
2. Operant conditioning refers to the manipulation of selected reinforcers to elicit and strengthen desired behavioral responses; the reinforcer refers to the consequence of the behavior, which is defined as anything that increases the occurrence of a behavior (Fig. 64-2).
3. In classical conditioning (respondent conditioning), the individual responds to a stimulus but is basically a passive agent (see Fig. 64-2).
4. Desensitization is a form of behavior therapy whereby exposure to increasing increments of a feared stimulus is paired with increasing levels of relaxation, which helps reduce the intensity of fear to a more tolerable level.
5. Aversion therapy is a form of behavior therapy whereby negative reinforcement is used to change behavior; for example, a stimulus attractive to the client is paired with an unpleasant event in hopes of endowing the stimulus with negative properties, thereby dissuading the behavior.
6. Modeling is behavioral therapy whereby the therapist acts as a role model for specific identified behaviors so that the client learns through imitation.

D. Cognitive therapy
1. An active, directive, time-limited, structured approach used to treat various mental health problems, including anxiety and depressive problems
2. It is based on the principle that how individuals feel and behave is determined by how they think about the world and their place in it; their cognitions are based on the attitudes or assumptions developed from previous experiences.
3. Therapeutic techniques are designed to identify, reality-test, and correct distorted conceptualizations and the dysfunctional beliefs underlying these cognitions.
4. The therapist helps the individual change the way she or he thinks, thereby reducing symptoms.
E. Group development and group therapy

1. Involves a leader such as a therapist, nurse, or other designated health care team member and, ideally, 5 to 8 members working on their individual goals within the context of a group, which presumably increases the opportunity for feedback and support

2. Initial development of the group
   a. Involves superficial rather than open and trusting communication
   b. Members become acquainted with each other and search for similarities among themselves.
   c. Members may be unclear about the purpose or goals of the group.
   d. Group norms, roles, and responsibilities are established.
   e. The work of termination begins and is expanded upon throughout the duration of the group.

3. Working in the group
   a. The real work of the group is accomplished.
   b. Members are familiar with one another, the group leader, and the group roles and feel free to address and attempt to solve their problems.
   c. Both conflict and cooperation surface during the group’s work as the members learn to work with one another.

4. Termination of the group
   a. Begins with the initial meeting
   b. Members’ feelings are explored regarding their accomplishments and the impending termination of the group.
   c. The termination stage provides an opportunity for members to learn to deal more realistically and comfortably with this normal part of human experience.

5. Self-help or support groups (Box 64-3)

Support groups are based on the premise that individuals who
have experienced and are insightful concerning a problem are able to help others who have a similar problem.

F. Family therapy

1. Family therapy is a specific intervention mode based on the premise that the member with the presenting symptoms signals the presence of problems in the entire family; this premise also assumes that a change in 1 member will bring about changes in other members.

2. The therapist works to assist family members to identify and express their thoughts and feelings; define family roles and rules; try new, more productive styles of relating; and restore strength to the family.

Table 64-1

Therapeutic (Effective) and Nontherapeutic (Ineffective) Communication Techniques
**Box 64-1**

**Types of Defense Mechanisms**

**Compensation:** Putting forth extra effort to counterbalance perceived deficiencies by emphasizing strengths.

**Conversion:** The expression of emotional conflicts through physical symptoms that have no organic cause.

**Denial:** Ignoring the existence of unpleasant or intolerable thoughts, feelings, needs, or impulses.

**Displacement:** Feelings about a person, object, or situation are directed to another less-threatening person, object, or situation.
Dissociation: The blocking of an anxiety-provoking event or period of time from the consciousness, memory, or perception to compartmentalize uncomfortable or unpleasant aspects of oneself.

Identification: The conscious or unconscious attempt to change oneself to resemble an admired person.

Insulation: Withdrawing into passivity and becoming inaccessible so as to avoid further threatening situations.

Intellectualization: Excessive reasoning of an event based solely on facts without involving feeling or emotion; the thinking is disconnected from feelings, and situations are dealt with at a cognitive level.

Introjection: A type of identification in which the individual incorporates the traits or values of another into herself or himself.

Isolation: Response in which a person blocks feelings associated with an unpleasant experience.

Projection: Transferring one’s internal feelings, thoughts, and unacceptable ideas and traits to someone else.

Rationalization: An attempt to make unacceptable feelings and behaviors acceptable by justifying the behavior.

Reaction Formation: Developing conscious attitudes and behaviors and acting out behaviors opposite to what one really feels.

Regression: Returning to an earlier developmental stage and pattern of behavior to express an impulse to deal with anxiety.

Repression: An unconscious process in which the client blocks undesirable and unacceptable thoughts or ideas from conscious expression.

Sublimation: Unconscious replacement of a mature and socially acceptable need, attitude, or emotion with one more immature and unacceptable one.

Substitution: The replacement of a valued unacceptable object with an object more acceptable to the ego.

Suppression: The conscious, deliberate denial of unacceptable or painful situation, thought, idea, or feeling.

---

**Box 64-2**

**Client Rights**

- Right to communicate with people outside the hospital through correspondence, telephone, and personal visits
- Right to keep clothing and personal effects with them in the hospital
- Right to religious freedom
- Right to be employed if possible
- Right to manage and dispose of property
- Right to execute wills
- Right to enter into contractual relationships
- Right to make purchases
- Right to education
• Right to habeas corpus
• Right to independent mental health examination
• Right to civil service status
• Right to retain licenses, privileges, or permits established by law, such as a driver’s or professional license
• Right to sue or be sued
• Right to marry and divorce
• Right not to be subject to unnecessary mechanical restraints
• Right to periodic review of status
• Right to legal representation
• Right to privacy
• Right to informed consent
• Right to treatment
• Right to refuse treatment
• Right to treatment in the least restrictive setting

**Note:** State and province laws should always be followed.  

---

**FIG. 64-2** Respondent versus operant conditioning.

---

**Box 64-3**

**Self-Help and Support Groups**

• Adult Children of Alcoholics
• Al-Anon
- Alcoholics Anonymous
- Bereavement groups
- Cancer support groups
- Co-Dependents Anonymous
- Gamblers Anonymous
- Groups to help deal with caring for family members
- Groups to help deal with unexpected body image changes, such as mastectomy or colostomy
- Mental health support groups
- Narcotics Anonymous
- Overeaters Anonymous
- Parents without Partners
- Recovery groups, such as for those who have experienced trauma
- Smoking cessation groups

Practice Questions

787. A client with a diagnosis of depression who has attempted suicide says to the nurse, “I should have died. I’ve always been a failure. Nothing ever goes right for me.” Which response by the nurse demonstrates therapeutic communication?

1. “You have everything to live for.”
2. “Why do you see yourself as a failure?”
3. “Feeling like this is all part of being depressed.”
4. “You’ve been feeling like a failure for a while?”

788. The nurse visits a client at home. The client states, “I haven’t slept at all the last couple of nights.” Which response by the nurse demonstrates therapeutic communication?

1. “I see.”
2. “Really?”
3. “You’re having difficulty sleeping?”
4. “Sometimes I have trouble sleeping too.”

789. A client experiencing disturbed thought processes believes that his food is being poisoned. Which communication technique should the nurse use to encourage the client to eat?

1. Using open-ended questions and silence
2. Sharing personal preference regarding food choices
3. Documenting reasons why the client does not want to eat
4. Offering opinions about the necessity of adequate nutrition

790. The nurse should plan which goals of the termination stage of group development? Select all that apply.

- 1. The group evaluates the experience.
- 2. The real work of the group is accomplished.
3. Group interaction involves superficial conversation.
4. Group members become acquainted with one another.
5. Some structuring of group norms, roles, and responsibilities takes place.
6. The group explores members’ feelings about the group and the impending separation.

791. A client diagnosed with terminal cancer says to the nurse, “I’m going to die, and I wish my family would stop hoping for a cure! I get so angry when they carry on like this. After all, I’m the one who’s dying.” Which response by the nurse is therapeutic?
   1. “Have you shared your feelings with your family?”
   2. “I think we should talk more about your anger with your family.”
   3. “You’re feeling angry that your family continues to hope for you to be cured?”
   4. “You are probably very depressed, which is understandable with such a diagnosis.”

792. On review of the client’s record, the nurse notes that the admission was voluntary. Based on this information, the nurse plans care anticipating which client behavior?
   1. Fearfulness regarding treatment measures
   2. Anger and aggressiveness directed toward others
   3. An understanding of the pathology and symptoms of the diagnosis
   4. A willingness to participate in the planning of the care and treatment plan

793. A client admitted voluntarily for treatment of an anxiety problem demands to be released from the hospital. Which action should the nurse take initially?
   1. Contact the client’s health care provider (HCP).
   2. Call the client’s family to arrange for transportation.
   3. Attempt to persuade the client to stay “for only a few more days.”
   4. Tell the client that leaving would likely result in an involuntary commitment.

794. When reviewing the admission assessment, the nurse notes that a client was admitted to the mental health unit involuntarily. Based on this type of admission, the nurse should provide which intervention for this client?
   1. Monitor closely for harm to self or others.
   2. Assist in completing an application for admission.
   3. Supply the client with written information about her or his mental health problem.
   4. Provide an opportunity for the family to discuss why they felt the admission was needed.

795. When a client is admitted to an inpatient mental health unit with the diagnosis of anorexia nervosa, a cognitive behavioral approach is used as part of the treatment plan. The nurse plans care based on which purpose of this approach?
1. Providing a supportive environment
2. Examining intrapsychic conflicts and past issues
3. Emphasizing social interaction with clients who withdraw
4. Helping the client to examine dysfunctional thoughts and beliefs

796. A client is preparing to attend a Gamblers Anonymous meeting for the first time. The nurse should tell the client that which is the first step in this 12-step program?
1. Admitting to having a problem
2. Substituting other activities for gambling
3. Stating that the gambling will be stopped
4. Discontinuing relationships with people who gamble

797. The nurse employed in a mental health clinic is greeted by a neighbor in a local grocery store. The neighbor says to the nurse, “How is Carol doing? She is my best friend and is seen at your clinic every week.” Which is the most appropriate nursing response?
1. “I cannot discuss any client situation with you.”
2. “If you want to know about Carol, you need to ask her yourself.”
3. “Only because you’re worried about a friend, I’ll tell you that she is improving.”
4. “Being her friend, you know she is having a difficult time and deserves her privacy.”

798. The nurse calls security and has physical restraints applied to a client who was admitted voluntarily when the client becomes verbally abusive, demanding to be discharged from the hospital. Which represents the possible legal ramifications for the nurse associated with these interventions? Select all that apply.

1. Libel
2. Battery
3. Assault
4. Slander
5. False imprisonment

799. The nurse in the mental health unit plans to use which therapeutic communication techniques when communicating with a client? Select all that apply.

1. Restating
2. Active listening
3. Asking the client “Why?”
4. Maintaining neutral responses
5. Providing acknowledgment and feedback
6. Giving advice and approval or disapproval

800. What is the most appropriate nursing action to help manage a manic client who is monopolizing a group therapy session?
1. Ask the client to leave the group for this session only.
2. Refer the client to another group that includes other manic clients.
3. Tell the client to stop monopolizing in a firm but compassionate manner.
4. Thank the client for the input, but inform the client that others now need a chance to contribute.

801. A client is participating in a therapy group and focuses on viewing all team members as equally important in helping the clients meet their goals. The nurse is implementing which therapeutic approach?
1. Milieu therapy
2. Interpersonal therapy
3. Behavior modification
4. Support group therapy

802. The nurse is working with a client who, despite making a heroic effort, was unable to rescue a neighbor trapped in a house fire. Which client-focused action should the nurse engage in during the working phase of the nurse–client relationship?
1. Exploring the client’s ability to function
2. Exploring the client’s potential for self-harm
3. Inquiring about the client’s perception or appraisal of why the rescue was unsuccessful
4. Inquiring about and examining the client’s feelings for any that may block adaptive coping

Answers

787. Answer: 4

Rationale: Responding to the feelings expressed by a client is an effective therapeutic communication technique. The correct option is an example of the use of restating. The remaining options block communication because they minimize the client’s experience and do not facilitate exploration of the client’s expressed feelings. In addition, use of the word why is nontherapeutic because clients frequently interpret why questions as accusations. Why questions can cause resentment, insecurity and mistrust.

Test-Taking Strategy: Use therapeutic communication techniques to direct you to the option that directly addresses the client’s feelings and concerns. Also, the correct option is the only one stated in the form of a question that is open-ended, which will encourage the verbalization of feelings.

Level of Cognitive Ability: Applying
Client Needs: Psychosocial Integrity
Integrated Process: Communication and Documentation
Content Area: Mental Health
Health Problem: Mental Health: Therapeutic Communication
Priority Concepts: Communication; Mood and Affect
788. **Answer:** 3

**Rationale:** The correct option uses the therapeutic communication technique of restatement. Although restatement is a technique that has a prompting component to it, it repeats the client’s major theme, which assists the nurse to obtain a more specific perception of the problem from the client. The remaining options are not therapeutic responses because none of them encourages the client to expand on the problem. Offering personal experiences moves the focus away from the client and onto the nurse.

**Test-Taking Strategy:** Use **therapeutic communication techniques.** “I see” is a general lead but does not provide the client with the opportunity to continue the discussion. “Really?” is a response that may make the client feel that she or he is not believed. Providing personal experiences focuses on the nurse’s problem and thus minimizes the client’s concerns. The correct option will provide information about the perception of the problem from the client’s perspective.

**Level of Cognitive Ability:** Applying
**Client Needs:** Psychosocial Integrity
**Integrated Process:** Communication and Documentation
**Content Area:** Mental Health
**Health Problem:** Mental Health: Therapeutic Communication
**Priority Concepts:** Communication; Sleep

789. **Answer:** 1

**Rationale:** Open-ended questions and silence are strategies used to encourage clients to discuss their problems. Sharing personal food preferences is not a client-centered intervention. The remaining options are not helpful to the client because they do not encourage the client to express feelings. The nurse should not offer opinions and should encourage the client to identify the reasons for the behavior.

**Test-Taking Strategy:** Use **therapeutic communication techniques.** First eliminate options that do not support the client’s expression of feelings. Any option that is not client-centered should be eliminated next. Focusing on the client’s feelings will direct you to the correct option.

**Level of Cognitive Ability:** Applying
**Client Needs:** Psychosocial Integrity
**Integrated Process:** Communication and Documentation
**Content Area:** Mental Health
**Health Problem:** Mental Health: Therapeutic Communication
**Priority Concepts:** Communication; Psychosis
**Reference:** Varcarolis (2017), pp. 92, 95.

790. **Answer:** 1, 6

**Rationale:** The stages of group development include the initial stage, the working stage, and the termination stage. During the initial stage, the group members become acquainted with one another, and some structuring of group norms, roles, and
responsibilities takes place. During the initial stage, group interaction involves superficial conversation. During the working stage, the real work of the group is accomplished. During the termination stage, the group evaluates the experience and explores members’ feelings about the group and the impending separation.

**Test-Taking Strategy:** Focus on the subject, the termination stage. Reading each item presented and recalling the stages of group development and the definition of termination will assist you in answering this question.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Nursing Process—Planning

**Content Area:** Mental Health

**Health Problem:** N/A

**Priority Concepts:** Collaboration; Communication

791. **Answer:** 3

**Rationale:** Restating is a therapeutic communication technique in which the nurse repeats what the client says to show understanding and to review what was said. Although it is appropriate for the nurse to attempt to assess the client’s ability to discuss feelings openly with family members, it does not help the client discuss the feelings causing the anger. The nurse’s direct attempt to expect the client to talk more about the anger is premature. The nurse would never make a judgment regarding the reason for the client’s feeling; this is nontherapeutic in the one-to-one relationship.

**Test-Taking Strategy:** Use therapeutic communication techniques. The correct option is the only one that identifies the use of a therapeutic technique (restatement) and focuses on the client’s feelings.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Communication and Documentation

**Content Area:** Mental Health

**Health Problem:** Mental Health: Therapeutic Communication

**Priority Concepts:** Communication; Family Dynamics

792. **Answer:** 4

**Rationale:** In general, clients seek voluntary admission. If a client seeks voluntary admission, the most likely expectation is that the client will participate in the treatment program since she or he is actively seeking help. The remaining options are not characteristics of this type of admission. Fearfulness, anger, and aggressiveness are more characteristic of an involuntary admission. Voluntary admission does not guarantee that a client understands her or his mental health problem, only the client’s desire for help.

**Test-Taking Strategy:** Focus on the subject, voluntary admission. This should direct you to the correct option. Note the relationship between the word **voluntary**
and the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Crisis  
**Priority Concepts:** Adherence; Caregiving  

793. **Answer:** 1

**Rationale:** In general, clients seek voluntary admission. Voluntary clients have the right to demand and obtain release, unless they pose an immediate danger to themselves or others, in which case the admission could become involuntary depending on the circumstances and regulations in that area and facility. The nurse needs to be familiar with the state and facility policies and procedures. The initial nursing action is to contact the PHCP, who has the authority to discuss discharge with the client. While arranging for safe transportation is appropriate, it is premature in this situation and should be done only with the client’s permission. While it is appropriate to discuss why the client feels the need to leave and the possible outcomes of leaving against medical advice, attempting to get the client to agree to staying “for only a few more days” has little value and will not likely be successful. Many states require that the client submit a written release notice to the facility psychiatrist, who reevaluates the client’s condition for possible conversion to involuntary status if necessary, according to criteria established by law. While this is a possibility, it should not be used as a threat with the client.

**Test-Taking Strategy:** Note the **strategic word**, **initially**. Noting the type of hospital admission will assist in directing you to the correct option while eliminating those that are unlikely to occur. Calling the family should be eliminated, based on the issues of client rights and confidentiality. To “persuade” a client to stay in the hospital is inappropriate. Threatening the client is inappropriate and illegal.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Leadership/Management: Ethical/Legal  
**Health Problem:** Mental Health: Crisis  
**Priority Concepts:** Clinical Judgment; Health Care Law  
**Reference:** Varcarolis (2017), pp. 63-64.

794. **Answer:** 1

**Rationale:** Involuntary admission is necessary when a person is a danger to self or others or is in need of psychiatric treatment regardless of the client’s willingness to consent to the hospitalization. A written request is a component of a voluntary admission. Providing written information regarding the mental health problem, is likely premature initially. The family may have had no role to play in the client’s admission.
Test-Taking Strategy: Focus on the subject, involuntary admission. Use Maslow’s Hierarchy of Needs theory. Safety is the priority if a physiological need does not exist. This should direct you to the correct option. Also, note that the remaining options are not always true of an involuntary admission.

Level of Cognitive Ability: Applying
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Mental Health
Health Problem: Mental Health: Crisis
Priority Concepts: Interpersonal Violence; Safety

795. Answer: 4

Rationale: Cognitive behavioral therapy is used to help the client identify and examine dysfunctional thoughts and to identify and examine values and beliefs that maintain these thoughts. The remaining options, while therapeutic in certain situations, are not the focus of cognitive behavioral therapy.

Test-Taking Strategy: Focus on the subject, the purpose of a cognitive behavioral approach. Note the relationship of the word cognitive in the question and thoughts in the correct option.

Level of Cognitive Ability: Applying
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Planning
Content Area: Mental Health
Health Problem: Mental Health: Eating Disorders
Priority Concepts: Caregiving; Cognition

796. Answer: 1

Rationale: The first step in the 12-step program is to admit that a problem exists. Substituting other activities for gambling may be a strategy, but it is not the first step. The remaining options are not realistic strategies for the initial step in a 12-step program.

Test-Taking Strategy: Focus on the subject, the first step in the 12-step program. This will assist in directing you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Mental Health
Health Problem: Mental Health: Addictions
Priority Concepts: Addiction; Caregiving

797. Answer: 1
**Rationale:** The nurse is required to maintain confidentiality regarding the client and the client’s care. Confidentiality is basic to the therapeutic relationship and is a client’s right. The most appropriate response to the neighbor is the statement of that responsibility in a direct, but polite manner. A blunt statement that does not acknowledge why the nurse cannot reveal client information may be taken as disrespectful and uncaring. The remaining options identify statements that do not maintain client confidentiality.

**Test-Taking Strategy:** Note the strategic words, most appropriate. Focusing on maintaining confidentiality will direct you to the correct option. This focus will also assist you in eliminating options that inappropriately give such information without being unnecessarily blunt or rude.

**Level of Cognitive Ability:** Applying

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Communication and Documentation

**Content Area:** Leadership/Management: Ethical/Legal

**Health Problem:** Mental Health: Therapeutic Communication

**Priority Concepts:** Ethics; Health Care Law

798. Answer: 2, 3, 5

**Rationale:** False imprisonment is an act with the intent to confine a person to a specific area. The nurse can be charged with false imprisonment if the nurse prohibits a client from leaving the hospital if the client has been admitted voluntarily and if no agency or legal policies exist for detaining the client. Assault and battery are related to the act of restraining the client in a situation that did not meet criteria for such an intervention. Libel and slander are not applicable here since the nurse did not write or verbally make untrue statements about the client.

**Test-Taking Strategy:** Focus on the subject, legal ramifications of nursing actions related to hospital admission. Noting the words admitted voluntarily will assist you in selecting the options related to inappropriately preventing the client from leaving the hospital, a right to which a voluntarily committed client is entitled. The remaining options do not relate to acts that prevent the client from leaving the hospital.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Leadership/Management: Ethical/Legal

**Health Problem:** N/A

**Priority Concepts:** Health Care Law; Safety

799. Answer: 1, 2, 4, 5

**Rationale:** Therapeutic communication techniques include listening, maintaining silence, maintaining neutral responses, using broad openings and open-ended questions, focusing and refocusing, restating, clarifying and validating, sharing
perceptions, reflecting, providing acknowledgment and feedback, giving information, presenting reality, encouraging formulation of a plan of action, providing nonverbal encouragement, and summarizing. Asking “Why” is often interpreted as being accusatory by the client and should also be avoided. Providing advice or giving approval or disapproval are barriers to communication.

**Test-Taking Strategy:** Use therapeutic communication techniques. This will assist you in both selecting the correct answers and eliminating the examples of nontherapeutic communication.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Communication and Documentation  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Therapeutic Communication  
**Priority Concepts:** Caregiving; Communication  
**Reference:** Varcarolis (2017), pp. 95, 98.

800. Answer: 4

**Rationale:** If a client is monopolizing the group, the nurse must be direct and decisive. The best action is to thank the client and suggest that the client stop talking and try listening to others. Although telling the client to stop monopolizing in a firm but compassionate manner may be a direct response, the correct option is more specific and provides direction for the client. The remaining options are inappropriate because they are not directed toward helping the client in a therapeutic manner.

**Test-Taking Strategy:** Note the strategic words, most appropriate. Use therapeutic communication techniques to assist in directing you to the correct option. Note that the correct option is specific and provides direction for the client.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Therapeutic Communication  
**Priority Concepts:** Communication; Mood and Affect  

801. Answer: 1

**Rationale:** All treatment team members are viewed as significant and valuable to the client’s successful treatment outcomes in milieu therapy. Interpersonal therapy is based on a one-to-one or group therapy approach in which the therapist–client relationship is often used as a way for the client to examine other relationships in her or his life. Behavior modification is based on rewards and punishment. Support groups are based on the premise that individuals who have experienced and are insightful concerning a problem are able to help others who have a similar problem.

**Test-Taking Strategy:** Focus on the subject, characteristics of a type of therapy. Note the relationship between the words helping the clients to meet their goals and the
correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Mental Health

**Health Problem:** N/A

**Priority Concepts:** Care Coordination; Caregiving

**Reference:** Varcarolis (2017), p. 86.

802. **Answer:** 4

**Rationale:** The client must first deal with feelings and negative responses before the client can work through the meaning of the crisis. The correct option pertains directly to the client’s feelings and is client-focused. The remaining options do not directly focus on or address the client’s feelings.

**Test-Taking Strategy:** Focus on the **subject**, the working phase of the nurse–client relationship. Also, note the words **client-focused action**. Think about the interventions that occur in this phase. Select the option that focuses on the feelings of the client.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Nursing Process: Implementation

**Content Area:** Mental Health

**Health Problem:** Mental Health: Crisis

**Priority Concepts:** Communication; Coping

CHAPTER 65

Mental Health Problems

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Mood and Affect; Safety

I. Anxiety
   A. Description
      1. A normal response to stress
      2. A subjective experience that includes feelings of apprehension, uneasiness, uncertainty, or dread
      3. Occurs as a result of a threat that may be misperceived or misinterpreted or a threat to identity or self-esteem
      4. Anxiety may result when values are threatened, or preceding new experiences.
   B. Types of anxiety
      1. Normal: A healthy type of anxiety
      2. Acute: Precipitated by imminent loss or change that threatens one’s sense of security
      3. Chronic: Anxiety that persists as a characteristic response to daily activities
   C. Levels of anxiety
      1. Mild
         a. Mild anxiety is associated with tense experiences that occur in everyday life.
         b. Increased ability to grasp information
         c. Sense of sight and sound are increased.
         d. Perceptual field is increased.
         e. Can be motivating, produce growth, enhance creativity, and increase learning
         f. Physical symptoms may include restlessness, irritability, or mild tension.
      2. Moderate
         a. The focus is on immediate concerns.
         b. Narrowed perceptual field
         c. Sense of sight and sound diminish as
selective inattentiveness occurs.

d. Learning and problem solving still occur.
e. Physical symptoms include increased heart rate, perspiration, gastric discomfort, headache, urinary urgency, and/or mild tremors.

3. Severe

a. Severe anxiety is a feeling that something bad is about to happen.
b. A significant narrowing in the perceptual field occurs.
c. Focus is on minute or scattered details.
d. All behavior is aimed at relieving the anxiety.
e. Learning and problem solving are not possible.
f. Actions are aimed at reducing or alleviating anxiety.
g. Physical symptoms are caused by stimulation of the sympathetic nervous system (e.g., headache, nausea, dizziness, sleep disturbances), increased tremors, pounding heart rate, and hyperventilation.

h. The individual needs direction to focus.

4. Panic

a. Associated with dread and terror and a sense of impending doom
b. Disorganization, difficulty perceiving reality, and inability to concentrate
c. Loss of rational thoughts with distorted perception occurs.
d. The individual is unable to communicate or function effectively.
e. If prolonged, panic can lead to exhaustion and death.
f. Increased motor activity (pacing, shouting, screaming) or withdrawal

g. Impulsive and erratic behavior

D. Interventions: General nursing measures (see Priority Nursing Actions)
Priority Nursing Actions

Anxiety in a Client

1. Provide a calm environment, decrease environmental stimuli, and stay with the client.
2. Ask the client to identify what and how she or he feels.
3. Encourage the client to describe and discuss her or his feelings.
4. Help the client identify the causes of the feelings if she or he is having difficulty doing so.
5. Listen to the client for expressions of helplessness and hopelessness.
6. Document the event, significant information, actions taken and follow-up actions, and the client’s response.

Reference

1. Recognize the anxiety.
2. Establish trust.
3. Protect the client.
4. Modify the environment by setting limits or limiting interaction with others.
5. Do not criticize coping mechanisms.
6. Provide creative outlets.
7. Monitor for signs of impending destructive behavior.
8. Promote relaxation techniques, such as breathing exercises or guided imagery.
9. Monitor vital signs, and administer antianxiety medications as prescribed.
10. Do not force the client into situations that provoke anxiety.

The immediate nursing action for a client with anxiety is to decrease stimuli in the environment and provide a calm and quiet environment.

E. Interventions: Mild to moderate levels

1. Help the client identify the source of their anxiety.
2. Encourage the client to talk about feelings and concerns.
3. Help the client identify thoughts and feelings that occurred before the onset of anxiety.
4. Encourage problem solving.
5. Encourage gross motor exercise.

F. Interventions: Severe to panic levels

1. Reduce the anxiety quickly.
2. Use a calm manner.
3. Always remain with the client.
4. Minimize environmental stimuli.
5. Provide clear, simple statements.
6. Use a low-pitched voice.
7. Attend to the physical needs of the client.
8. Provide gross motor activity.
9. Administer antianxiety medications as prescribed.
10. Ensure safety.

II. Generalized Anxiety Disorder
   A. Description (Box 65-1)
      1. Generalized anxiety disorder is an unrealistic anxiety about everyday worries that persists more days than not, over at least 6 months, and is not associated with another mental health or medical problem.
      2. Physical symptoms occur.
   B. Assessment
      1. Restlessness and inability to relax
      2. Episodes of trembling and shakiness
      3. Chronic muscular tension
      4. Dizziness
      5. Inability to concentrate
      6. Chronic fatigue and sleep problems
      7. Inability to recognize the connection between the anxiety and physical symptoms
   8. Client is focused on the physical discomfort.
   C. Unexpected and expected panic attacks
      1. Description
         a. Most extreme level of anxiety resulting in disturbed behavior
         b. Produces a sudden onset of feelings of intense apprehension and dread
         c. Cause usually cannot be identified.
         d. Severe, recurrent, intermittent anxiety attacks lasting 5 to 30 minutes occur.
      2. Assessment
         a. Choking sensation
         b. Labored breathing
         c. Pounding heart
         d. Chest pain
         e. Dizziness
         f. Nausea
         g. Blurred vision
         h. Numbness or tingling of the extremities
i. Sense of unreality and helplessness  
j. Fear of being trapped  
k. Fear of dying  

3. Interventions  
a. Remain with the client.  
b. Attend to physical symptoms.  
c. Assist the client to identify the thoughts that aroused the anxiety and identify the basis for these thoughts.  
d. Assist the client to change the unrealistic thoughts to more realistic thoughts.  
e. Use cognitive restructuring to replace distorted thinking.  
f. Administer antianxiety medications if prescribed.  

III. Post-traumatic Stress Disorder  
A. Description: After experiencing a psychologically traumatic event, the individual is prone to re-experience the event and have recurrent and intrusive dreams or flashbacks.  
B. Diagnosis: Symptoms last at least 1 month and can occur months to years after the traumatizing events.  
C. Stressors  
   1. Natural disaster  
   2. Terrorist attack  
   3. Combat experiences  
   4. Accidents  
   5. Rape  
   6. Crime or violence  
   7. Sexual, physical, and emotional abuse  
   8. Re-experiencing the event as flashbacks  
D. Assessment  
   1. Avoidance or numbness  
   2. Irritability or outbursts of anger  
   3. Detachment  
   4. Depression that may involve suicidal thoughts  
   5. Anxiety  
   6. Sleep disturbances and nightmares  
   7. Flashbacks of event  
   8. Hypervigilance and exaggerated startle response  
   9. Guilt about surviving the event  
   10. Poor concentration and avoidance of activities that trigger the memory of the event  
E. Interventions (Box 65-2)
Clients dealing with cancer may develop post-traumatic stress (PTS). Cancer-related PTS can occur anytime during or after treatment. The symptoms of PTS are similar to those of post-traumatic stress disorder but are generally not as severe.

IV. Specific Phobia
A. Description
1. Irrational fear of an object, activity, or situation that persists and that leads to avoidance.
2. Associated with panic-level anxiety or fear if the object, situation, or activity cannot be avoided.
3. **Defense mechanisms** commonly used include repression and displacement.

B. Types *(Box 65-3)*

C. Interventions
1. Identify the basis of the anxiety.
2. Allow the client to verbalize feelings about the anxiety-producing object or situation; talking frequently about the feared object is the first step in the desensitization process.
3. Teach relaxation techniques, such as breathing exercises, muscle relaxation exercises, and visualization of pleasant situations.
4. Promote desensitization by gradually introducing the individual to the feared object or situation in small doses.

Always stay with the client who is experiencing anxiety to promote safety and security. Never force the client to have contact with the phobic object or situation.

V. Obsessive-Compulsive and Related Disorders
A. Obsessions: Preoccupation with persistently intrusive thoughts, impulses, or images and ideas
B. Compulsions: The performance of rituals or repetitive behaviors an individual is driven to perform to prevent some event, divert unacceptable thoughts, and decrease anxiety.
1. Obsessions and compulsions often occur together and can disrupt normal daily activities.
2. Anxiety occurs when one resists obsessions or compulsions and from being powerless to resist the thoughts or rituals.
3. Obsessive thoughts can involve issues of
violence, aggression, sexual behavior, orderliness, or
religion and uncontrollably can interrupt conscious
thoughts and the ability to function.

C. Compulsive behavior patterns (behaviors or rituals)
   1. Compulsive behavior patterns decrease the anxiety.
   2. The patterns are associated with the obsessive
      thoughts.
   3. The patterns neutralize the thought.
   4. During stressful times, the ritualistic behavior
      increases.
   5. Defense mechanisms include repression,
      displacement, and undoing.

D. Related disorders
   1. Hoarding disorder
   2. Excoriation (skin-picking) disorder
   3. Substance- or medication-induced obsessive-
      compulsive and related disorder
   4. Obsessive-compulsive and related disorder due to
      another medical condition
   5. Trichotillomania (hair-pulling disorder)

E. Interventions (Box 65-4)

VI. Somatic Symptom and Related Disorders
   A. Description
      1. Somatic symptom disorders are characterized by a
         combination of persistent worry or complaints and an
         associated maladaptive response regarding physical
         illness without supportive physical findings and
         medical diagnosis.
      2. The client focuses on the physical signs and symptoms
         and is unable to control the signs and symptoms.
      3. The physical signs and symptoms increase with
         psychosocial stressors and result in a high level of
         functional impairment.
      4. The anxiety is redirected into a somatic concern.
      5. The client may unconsciously somatize for
         secondary gains, such as increased attention and
         decreased responsibilities.

B. Conversion disorder (functional neurological symptom
   disorder)
   1. Description
      a. The sudden onset of a neurological
         symptom or a deficit in the absence of
         a neurological cause or diagnosis.
      b. Conversion disorder is an expression of
a psychological conflict or need.  
c. The most common conversion  
symptoms are blindness, deafness,  
numbness, paralysis, gait disturbance,  
and the inability to talk.  
d. Conversion disorder has no organic  
cause.  
e. Symptoms are beyond the conscious  
control of the client and are directly  
related to conflict.  
f. The development of physical symptoms  
reduces anxiety.  

2. Assessment  
   a. Rule out a physiological cause for  
symptoms or deficits.  
   b. “La belle indifference”: Unconcerned with  
symptoms  
   c. Physical limitation or disability  
   d. Feelings of guilt, anxiety, or frustration  
   e. Low self-esteem and feelings of  
inadequacy  
   f. Unexpressed anger or conflict  
   g. Secondary gain  
   h. History of physical or sexual abuse

C. Interventions  
   1. Obtain a nursing history and assess for physical  
problems.  
   2. Explore the needs being met by the physical  
symptoms with the client.  
   3. Assist the client to identify alternative ways of  
meeting needs.  
   4. Assist the client to relate feelings and conflicts  
to the physical symptoms.  
   5. Convey understanding that the physical  
symptoms are real to the client.  
   6. Assure the client that physical illness has been ruled  
out.  
   7. Report and assess any new physical complaint.  
   8. Use a pain assessment scale if the client complains of  
pain, and implement pain reduction measures as  
required.  
   9. Explore the source of anxiety and stimulate  
verbalization of anxiety.  
  10. Assist the client in recognizing her or his own feelings  
and emotions.
11. Encourage the use of relaxation techniques as the anxiety increases.
12. Encourage diversional activities.
13. Provide positive feedback.

For a client with a somatic symptom disorder, allow a specific time period for the client to discuss physical complaints, because the client will feel less threatened if this behavior is limited rather than stopped completely. Avoid responding with positive reinforcement about the physical complaints.

VII. Dissociative Disorder
   A. Description
      1. Dissociative disorder is a disruption in integrative functions of memory, consciousness, or identity.
      2. It is associated with exposure to an extremely traumatic event.
   B. Dissociative identity disorder (DID), formerly called multiple personality disorder
      1. Description
         a. Two or more fully developed, distinct, and unique personalities exist within the client and recurrently control behavior.
         b. The host is the primary personality, and the other personalities are referred to as alters.
         c. Alter personalities may take full control of the client, 1 at a time, and may or may not be aware of one another.
         d. The alters may be aware of the host, but the host is not usually aware of the alters.
      2. Assessment
         a. The client may have an inability to recall important information (unrelated to ordinary forgetfulness).
         b. Transition from 1 personality to the other is related to stress or a traumatic event and is sudden.
         c. Dissociation is used as a method of distancing and defending one’s self from anxiety and traumatizing experiences.
   C. Dissociative amnesia
      1. Description
         a. Inability to recall important personal
information often due to trauma or because it provokes anxiety.

b. Memory impairment may range from partial to almost complete.

c. The client may assume a new identity in a new environment, drift from place to place, develop few relationships, and then return home unable to remember the amnesia.

2. Assessment
   a. Localized: The client blocks out all memories about a specified period.
   b. Selective: The client recalls some but not all memories about a specified period.
   c. Generalized: The client has a loss of all memory about past life.

D. Depersonalization/derealization disorder
   1. Description: An altered self-perception in which one’s own reality is temporarily lost or changed
   2. Assessment
      a. Feelings of detachment
      b. Intact reality testing

E. Interventions
   1. Orient the client.
   2. Develop a trusting relationship with the client.
   3. Encourage verbal expression of painful experiences, anxieties, and concerns.
   4. Explore methods of coping.
   5. Identify sources of conflict.
   6. Focus on the client’s strengths and skills.
   7. Provide nondemanding, simple routines.
   8. Allow the client to progress at her or his own pace.
   10. Plan for individual, group, or family psychotherapy to integrate dissociated aspects of personality or memory and to expand self-awareness.

VIII. Mood Disorders

A. Bipolar and related disorders
   1. Description (Box 65-5)
      a. Bipolar disorder is characterized by extreme changes in mood, energy, and the ability to function.
      b. The classifications of bipolar include Bipolar I disorder, Bipolar II disorder,
cyclothymic disorder, and mixed features.

c. Bipolar I disorder: Most severe form characterized by severe mood episodes from mania to depression.

d. Bipolar II disorder: A milder form of mood elevation; there are milder episodes of hypomania that alternate with periods of severe depression.

e. Cyclothymic disorder: brief periods of hypomanic symptoms occur alternating with brief periods of depressive symptoms that are not as extensive or as long-lasting as seen in full hypomanic episodes or full depressive episodes.

f. Mixed features: the occurrence of simultaneous symptoms of opposite mood polarities during manic, hypomanic or depressive episodes. It's features are high energy, sleeplessness, and racing thoughts. At the same time, the individual may feel hopeless, despairing, irritable, and suicidal.

g. The medication of choice has traditionally been lithium carbonate, which can be toxic and requires regular monitoring of serum lithium levels to help keep the medication’s therapeutic index level appropriate; a stable intake of adequate dietary sodium and fluid (2 to 3 L daily) must be maintained to avoid toxicity.

h. Other medications may be prescribed both to reduce the symptoms of acute bipolar manic episodes and for maintenance therapy.

i. Antianxiety agents may be prescribed to assist in managing the psychomotor agitation characteristic of mania; these medications should be avoided in clients with a history of substance abuse.

j. Atypical antipsychotic medications may be prescribed for both their sedative and mood-stabilizing effects.
a. Assess and monitor whether the client is a danger to self or others.
b. Assess for alcohol or substance use/misuse.
c. Mood
d. Behavior
e. Speech (flight of ideas, tangential)
f. Cognitive functioning
g. Inflated self-regard (delusions of grandeur)
h. Sleeping pattern
i. Impulse control

3. Interventions for mania (Box 65-6)
   a. Remove hazardous objects from the environment (this should be done for all clients).
b. Assess the client closely for fatigue.
c. Provide frequent rest periods and monitor the client’s sleep patterns; use comfort measures to promote sleep.
d. Provide a private room if possible.
e. Encourage the client to ventilate feelings.
f. Use calm, slow interactions.
g. Help the client focus on 1 topic during the conversation.
h. Ignore or distract the client from grandiose thinking; present reality to the client.
i. Do not argue with the client.
j. Limit group activities and assess the client’s tolerance level; solitary activities may be necessary.
k. Provide high-calorie finger foods and fluids.
l. Reduce environmental stimuli.
m. Set limits on inappropriate behaviors.
n. Provide physical activities and outlets for tension.
o. Avoid competitive games.
p. Provide gross motor activities such as walking.
q. Provide structured activities or one-to-one activities with the nurse.
r. Provide simple and direct explanations for routine procedures.
s. Supervise the administration of medication.
3. Depression: See Section IX.

IX. Depressive Disorders

A. Description
   1. Depression affects feelings, thoughts, and behaviors.
   2. It can occur after a loss, including loss of self-esteem, the end of a significant relationship, the death of a loved one, or a traumatic event.
   3. The loss is followed by grief and mourning; if this process does not resolve, depression results.
   4. Depression may be mild, moderate, or severe.
   5. Treatment includes counseling, antidepressant medication, and electroconvulsive therapy (ECT).
   6. See Box 65-5 for general assessment findings.

B. Mild depression
   1. Mild depression is triggered by an external event and follows the normal grief reaction.
   2. Mild depression lasts less than 2 weeks.
   3. Feeling sad
   4. Feeling let down or disappointed
   5. Mild alterations in sleep patterns
   6. Feeling less alert
   7. Irritability
   8. Disinterested in spending time with others
   9. Increased or decreased appetite
   10. Increased use of substances such as alcohol or drugs

C. Moderate depression
   1. Moderate depression persists over time.
   2. The person experiences a sense of change and often seeks help.
   3. Despondent and gloomy
   4. Dejected
   5. Low self-esteem
   6. Helplessness and powerlessness
   7. May experience intense anxiety and anger
   8. Diurnal variation: The person may feel better at a certain time of the day.
   9. Slow thought processes and difficulty in concentrating
   10. Rumination: Persistent thinking about and discussion of a particular subject
   11. Negative thinking and suicidal thoughts (see Chapter 67)
   12. Sleep disturbances, early-morning awakening, or oversleeping
   13. Social withdrawal
   14. Anorexia, weight loss or gain, and fatigue
   15. Somatic complaints
   16. Moving or talking more slowly
17. Increased use of substances such as alcohol or drugs

D. Major depressive disorder
1. Depressed mood or loss of pleasure in activities for at least 2 weeks
2. Impaired social, occupational, and/or educational functioning
3. Mood change from person’s baseline
4. Daily, experiences at least 5 of the of the following symptoms:
   a. Irritability or depressed mood most of the day, nearly every day (subjective report or observation of others)
   b. Decreased interest or pleasure in most activities
   c. Significant weight change (5%) or change in appetite
   d. Change in activity level
   e. Fatigue or loss of energy
   f. Guilt/worthlessness
   g. Diminished ability to think or concentrate, or more indecisive
   h. Thoughts of death or suicide

E. Interventions (Box 65-7)

For a client at risk for self-harm, ask the client directly, “Have you thought of hurting yourself?”

X. Electroconvulsive Therapy (ECT)
A. Description
1. ECT is an effective treatment for depression (not a cure); a small amount of an electrical current is delivered through electrodes attached to the temples that cause a brief seizure within the brain; outward movement is usually a slight movement of the hands, feet, or a toe, because premedication is given to relax the muscles. In addition, a short-acting anesthetic is given.
2. The usual course is 6 to 12 treatments given every 2 to 5 days; maintenance ECT once a month may help decrease the relapse rate for a client with recurrent depression.
3. ECT is not always effective in clients with dysthymic depression, depression and personality disorders, drug dependence, or depression secondary to situational or social difficulties.
4. At-risk clients include clients with recent myocardial
infarction, stroke (brain attack), or intracranial mass lesions.

B. Uses (Box 65-8)

1. Clients with severe depressive and bipolar depressive disorders, especially when psychotic symptoms are present, such as delusions of guilt, somatic delusions, and delusions of infidelity
2. Clients who have depression with marked psychomotor retardation and stupor
3. Manic clients whose conditions are resistant to lithium and antipsychotic medications and clients who are rapid cyclers (a client with a bipolar disorder who has many episodes of mood swings close together)
4. Clients with schizophrenia (especially catatonia), clients with schizoaffective syndromes, and psychotic clients

C. Preprocedure

1. Explain the procedure to the client.
2. Encourage the client to discuss feelings, including myths regarding ECT.
3. Teach the client and family what to expect.
4. Informed consent must be obtained when voluntary clients are being treated.
5. For involuntary clients, when informed consent cannot be obtained, permission may be obtained from the next of kin, although in some states the permission for ECT must be obtained from the court.
6. Maintain NPO (nothing by mouth) status after midnight or at least 4 hours before treatment as prescribed.
7. Baseline vital signs are taken.
8. The client is requested to void.
9. Hairpins, contact lenses, and dentures are removed.
10. Administer preprocedure medication as prescribed.

D. During the procedure

1. As the intravenous line is inserted, electroencephalographic and electrocardiographic electrodes are attached.
2. The blood pressure, pulse, and oxygen saturation are monitored throughout the treatment.
3. A blood pressure cuff is placed around 1 ankle and inflated to block the medication from entering the foot. When the procedure begins, seizure activity can be monitored by watching for movement in that foot.
4. Medications administered may include a short-acting anesthetic and a muscle relaxant.
5. Oxygen is administered by face mask.
6. An airway or mouth guard is placed to prevent the
client biting the tongue.
7. An electrical stimulus is administered; a brief seizure occurs.

E. Postprocedure
1. The client is transported to a recovery area with the blood pressure cuff and oximeter in place, where oxygen, suction, and other emergency equipment are available.
2. Client wakes about 15 minutes after procedure.
3. When the client is awake, talk to the client and take vital signs.
4. The client may be confused and disoriented for several hours; provide frequent orientation (brief, distinct, and simple) and reassurance.
5. The client returns to the nursing unit when at least a 90% oxygen saturation level is maintained, vital signs are stable, and mental status is satisfactory.
6. Assess for a gag reflex before giving the client fluids, food, or medication.

F. Potential side effects
1. Confusion, disorientation, and short-term memory loss
2. The client may be confused and disoriented on awakening.
3. Other side effects include headache, hypotension, muscle soreness, nausea, and tachycardia.
4. Memory deficits may occur, but memory usually recovers completely, although some clients have memory loss lasting 6 months.

Monitor both a depressed client and a client who has recently been prescribed an antidepressant medication closely for signs of suicidal ideation. If the client presents with increased energy, monitor closely, because it could mean that the client now has the energy to perform the suicide act.

XI. Schizophrenia
A. Description
1. Schizophrenia is a group of mental health problems characterized by psychotic features (hallucinations and delusions), disordered thought processes, and disrupted interpersonal relationships.

2. Disturbances in affect, mood, behavior, and thought processes occur.
3. Treatment with medication controls symptoms associated with the mental health problem.

B. Assessment (Fig. 65-1)
1. Physical characteristics
   a. Unkempt appearance; may neglect hygiene, eating, sleeping, and elimination
   b. Body image distortions
   c. May be preoccupied with somatic complaints

2. Motor activity (Box 65-9)
   a. Catatonic posturing: Holding bizarre postures for long periods
   b. Catatonic excitement: Moving excitedly, with no environmental stimuli present
   c. Possible total immobilization
   d. Inability to respond to commands or responding only to commands
   e. Waxy flexibility
   f. Repetitive or stereotyped movements
   g. Motor activity that may be increased, as evidenced by agitation, pacing, inability to sleep, loss of appetite and weight, and impulsiveness
   h. Possible inability to initiate activity (anergia)

3. Emotional characteristics
   a. Mistrust
   b. View of the world as threatening and unsafe
   c. Affect blunted, flat, or inappropriate
   d. May display feelings of ambivalence, helplessness, anxiety, anger, guilt, or depression in response to hallucinations or delusions or as a result of grief related to losses imposed by the illness

4. Compulsive rituals: Constant repetitive activity performed as an attempt to solve conflicting feelings

5. Overcompliance: Attempt to deny responsibility for any action by doing only what another person instructs exactly

6. Affective disturbances
   a. Flat or incongruent affect or inappropriate affect
   b. Altered thought processes

7. Abnormal thought processes (Box 65-10)
   a. Impaired reality testing
   b. Fragmentation of thoughts
   c. Thought blocking
   d. Loose associations
e. Echolalia: Pathological repeating of another’s words
f. Distorted perception of the environment
g. Neologisms: Made-up words that have meaning only to the client
h. Magical thinking
i. Inability to conceptualize meaning in words or thoughts
j. Inability to organize facts logically
k. Delusions associated with thought processes or content

8. Types of delusions (Box 65-11)
   a. Loss of reference, in which the client believes that certain events, situations, or interactions are related directly to self
   b. Delusions of persecution, in which the client believes that she or he is being harassed, threatened, or persecuted by some powerful force
   c. Delusions of grandeur, in which the client attaches special significance to self in relation to others or the universe and has an exaggerated sense of self that has no basis in reality
   d. Somatic delusions, in which the client believes that her or his body is changing or responding in an unusual way, which has no basis in reality

9. Perceptual distortions
   a. Illusions, which may be brief experiences with a misinterpretation or misperception of reality
   b. Hallucinations (5 senses) with no basis in reality (Box 65-12), such as perceiving objects, sensations, or images

10. Language and communication disturbances (Box 65-13)
   a. Related to disorders in thought process
   b. Inability to organize language
   c. Difficulty communicating clearly
   d. Inappropriate responses to a situation
   e. A single word or phrase may represent the whole meaning of the conversation such that the client may feel that she or he has communicated adequately.
f. Development of a private language

C. Interventions: Schizophrenia (Box 65-14)

D. Interventions: Active hallucinations

1. Monitor for hallucination cues and assess content of hallucinations.
2. Intervene with one-on-one contact.
3. Decrease stimuli or move the client to another area.
4. Avoid conveying to the client that others also are experiencing the hallucination.
5. Respond verbally to anything real that the client talks about.
6. Avoid touching the client.
7. Encourage the client to express feelings.
8. During a hallucination, attempt to engage the client’s attention through a concrete activity.
9. Accept and do not joke about or judge the client’s behavior.
10. Provide easy activities and a structured environment with routine activities of daily living.
11. Monitor for signs of increasing fear, anxiety, or agitation.
12. Decrease stimuli as needed.
13. Administer medications as prescribed.

For a client with hallucinations, safety is the first priority; ensure that the client does not have an auditory command telling him or her to harm self or others.

E. Interventions: Delusions

1. Interact based on reality.
2. Encourage the client to express feelings.
3. Do not dispute the client or try to convince the client that delusions are false.
4. Initiate activities on a one-on-one basis.
5. Alter hospital routines as necessary, such as by using canned or packaged food or food from home.
6. Recognize accomplishments and provide positive feedback for successes.

XII. Personality Disorders

A. Description

1. Personality disorders involve the consistent expression of various inflexible maladaptive behavior patterns or
traits that may impair functioning and relationships.
2. The client usually remains in touch with reality and typically has a significant lack of insight in self-identity and interpersonal behavior (empathy or intimacy).
3. Stress exacerbates manifestations of the personality disorder.
4. Not directly associated with the effects of substance misuse or a general medical condition, such as severe head injury.

B. Characteristics
1. Poor impulse control
   a. Acting out to manage internal pain
   b. Forms of acting out include physical and verbal attacks, such as yelling and swearing, and self-injurious behaviors, such as cutting own skin, banging the head, punching self, manipulation, substance abuse, promiscuous sexual behaviors, and suicide attempts.
   c. The client may be preoccupied with such things as self, religion, or sex.
2. Mood characteristics
   a. May experience abandonment and depression
   b. Moods may include rage, guilt, fear, and emptiness.
3. Impaired judgment
   a. Difficulty with problem solving
   b. Inability to perceive the consequences of behavior
4. Impaired reality testing: Distortion of reality and often projection of own feelings onto others
5. Impaired object relations: Rigid and inflexible, with difficulty in intimate relationships
6. Impaired self-perception: Distorted self-perception and experience of self-hate or self-idealization
7. Impaired thought processes
   a. Concrete or diffuse thinking
   b. Difficulty concentrating
   c. Impaired memory
8. Impaired stimulus barrier
   a. Inability to regulate incoming sensory stimuli
   b. Increased excitability
   c. Excessive response to noise and light
   d. Poor attention span
   e. Agitation
f. Insomnia
C. Cluster A personality disorder types include the odd disorders—schizoid, schizotypal, and paranoid.

1. Schizoid personality disorder is characterized by an inability to form warm, close social relationships.
   a. Social detachment and lack of close relationships
   b. Interest in solitary activities
   c. Aloofness and indifference
   d. Restricted expression of emotions
   e. Lack of interest in others

2. Schizotypal personality disorder is characterized by the display of abnormal or highly unusual thoughts, perceptions, speech, and behavior patterns.
   a. Suspiciousness and paranoia
   b. Unable to understand how behaviors impact others
   c. Eccentricity
   d. Magical thinking
   e. Odd thinking and speech
   f. Relationship deficits
   g. Blunted affect
   h. Reclusiveness

3. Paranoid personality disorder is characterized by suspiciousness and mistrust of others (paranoia) (Box 65-15).
   a. May be suspicious and distrusting
   b. May be argumentative
   c. May be hostile or aloof
   d. May be rigid, critical, and controlling of others
   e. May have thoughts of grandiosity

Do not whisper or laugh in front of a client with a paranoid personality disorder, because the client will think that you are talking about or laughing at him or her; this increases the paranoia.

D. Cluster B personality disorders include the dramatic, emotional, erratic types—histrionic, narcissistic, antisocial, and borderline.

1. Histrionic personality disorder is characterized by overly dramatic and intensely expressive behavior.
   a. Lively and dramatic and enjoys being the center of attention
   b. Has poor and shallow interpersonal relationships
   c. May be sexually seductive or provocative
d. Dramatizes her or his life and may appear theatrical
e. Overly concerned with appearance
f. Easily bored

2. Narcissistic personality disorder is characterized by an increased sense of self-importance and preoccupation with fantasies and unlimited success.
   a. Need for admiration and inflation of accomplishments
   b. Overestimation of abilities and underestimation of contributions of others
   c. Lack of empathy and sensitivity to needs of others

3. Antisocial personality disorder comprises a pattern of irresponsible and antisocial behavior, selfishness, an inability to maintain lasting relationships, poor sexual adjustment, a failure to accept social norms, and a tendency toward irritability and aggressiveness.
   a. Perceives the world as hostile
   b. Lack of empathy and feelings of remorse
   c. Egocentrism and focused on personal gratification
d. Deceitful and manipulative
e. Irresponsible
   f. Impulsive and engages in risk taking behaviors
g. Persistent or frequent feelings of anger
   h. Refusal to conform to social rules and normative behavior

4. Borderline personality disorder is characterized by instability in interpersonal relationships, unstable mood and self-image, and impulsive and unpredictable behavior.
   a. Poor self-regard or unstable self-image
   b. Lack of self-direction
c. Unstable and intense personal relationships
d. Lack of empathy toward the needs and feelings of others
e. Extreme shifts in mood
   f. Impulsive
g. Engages in risk-taking behaviors
   h. Argumentative and hostile in response to perceived slights or insults
   i. Depression
   j. Manipulation
k. Intense feeling of anxiety in response to stress
l. Chronic feelings of emptiness and intense fear of being rejected
m. Splitting—sees others as all good or all bad; creates conflict between individuals by playing 1 person against another

E. Cluster C personality disorders include the anxious, fearful types of personality disorders—obsessive-compulsive personality, avoidant, and dependent.

1. Obsessive-compulsive personality disorder is characterized by difficulty expressing warm and tender emotions, perfectionism, stubbornness, the need to control others, and a devotion to work.
   a. Perfectionist with unreasonably high expectations of self
   b. Inflexible and preoccupied with details and rules
   c. Sense of self derived primarily from work
   d. Social and personal relationship viewed as secondary to work and productivity
   e. Difficulty understanding the ideas, feelings, and behaviors of others
   f. Engages in rituals

2. Avoidant personality disorder is characterized by social withdrawal and extreme sensitivity to potential rejection.
   a. Feelings of inadequacy
   b. Hypersensitive to reactions of others and poor reaction to criticism
   c. Social isolation
   d. Lack of support system

3. Dependent personality disorder is characterized by an intense lack of self-confidence, low self-esteem, and inability to function independently, such that the individual passively allows others to make decisions and assume responsibility for major areas in the person’s life; the dependent client has great difficulty making decisions.

F. General interventions for a client with a personality disorder

1. Maintain safety against self-destructive behaviors.
2. Ensure health care team is consistent with information and response to the client’s acting-out behaviors.
3. Allow the client to make choices and be as independent as possible.
4. Encourage the client to discuss feelings rather than act them out.
5. Encourage the client to keep a journal recording daily feelings.
6. Discuss expectations and responsibilities with the client.
7. Discuss the consequences that will follow certain behaviors.
8. Inform the client that harm to self, others, and property is unacceptable.
9. Develop a written safety or behavioral contract with the client.
10. Identify splitting behavior.
11. Assist the client to deal directly with anger.
12. Encourage the client to participate in group activities, and praise nonmanipulative behavior.
13. Set and maintain limits to decrease manipulative behavior.
14. Remove the client from group situations in which attention-seeking behaviors occur.
15. Provide realistic praise for positive behaviors in social situations.

XIII. Neurodevelopmental Disorders
   A. Autism spectrum disorder: See Chapter 38.
   B. Attention-deficit/hyperactivity disorder: See Chapter 38.

XIV. Neurocognitive Disorders
   A. Dementia and Alzheimer’s disease
      1. Dementia
         a. Dementia is a syndrome with progressive deterioration in intellectual functioning secondary to structural or functional changes.
         b. Long-term and short-term memory loss occurs, with impairment in judgment, abstract thinking, problem-solving ability, and behavior.
         c. Dementia results in a self-care deficit.
         d. Dementia-like symptoms can be a result of physiological conditions, and such conditions must be ruled out initially.
         e. The most common type of dementia is Alzheimer’s disease.
2. Alzheimer’s disease (Box 65-16)
   a. Alzheimer’s disease is an irreversible form of senile dementia caused by nerve cell deterioration.
   b. Individuals with Alzheimer’s disease experience cognitive deterioration and progressive loss of ability to carry out activities of daily living.
   c. The client experiences a steady decline in physical and mental functioning and usually requires long-term care in a specialized facility in the final stages of the illness.
   d. Stages and major characteristics of Alzheimer’s disease: Stage 1 (mild): forgetfulness; stage 2 (moderate): confusion; stage 3 (moderate to severe): ambulatory dementia; and stage 4 (late): end stage.

3. Interventions
   a. Identify and reinforce retained skills.
   b. Provide continuity of care.
   c. Orient the client to the environment.
   d. Furnish the environment with familiar possessions.
   e. Acknowledge the client’s feelings.
   f. Assist the client and family members to manage memory deficits and behavior changes.
   g. Encourage family members to express feelings about caregiving.
   h. Provide the caregiver with support and identify the resources and support groups available.
   i. Monitor the client’s activities of daily living.
   j. Remind the client how to perform self-care activities.
   k. Help the client maintain independence.
   l. Provide the client with consistent routines.
   m. Provide the client with exercise, such as walking with an escort.
   n. Avoid activities that tax the memory.
   o. Allow the client plenty of time to complete a task.
   p. Use constant encouragement with the
q. Provide the client with activities that distract and occupy time, such as listening to music, coloring, and watching television.
r. Provide the client with mental stimulation with simple games or activities.

4. Wandering

a. Provide the client with a safe environment free of clutter and hazardous items.
b. Provide safe ambulation, including comfortably and well-fitting shoes, mobility aids.
c. Provide close and frequent supervision.
d. Close and secure doors.
e. Use identification bracelets and electronic surveillance.
f. Encourage rest periods in the afternoon, because wandering worsens at night.
g. Provide regular supervised exercise or walking programs.
h. Sundown syndrome (sundowning) is characterized by a pronounced increase in symptoms and problem behaviors in the evening.

Providing a safe environment is a priority in the care of a client with Alzheimer’s disease.

5. Communication disorders

a. Disorders include language disorder (expressive–receptive disorder), speech sound disorder (phonological disorder), childhood-onset fluency disorder (stuttering disorder), and social communication disorder (impaired social communication).
b. Adapt to the communication level of the client.
c. Pay attention to nonverbal cues.
d. Use a firm volume and a low-pitched voice to communicate.
e. Stand directly in front of the client and maintain eye contact.
f. Give ample time for the client to respond.
g. Use a calm and reassuring voice. Do not speak loudly unless the client is hearing-impaired.
h. Use pantomime gestures if the client is unable to understand spoken words.
i. Speak slowly and clearly, using short words and simple sentences.
j. Ask only 1 question at a time and give 1 direction at a time.
k. Repeat questions if necessary, but do not rephrase.
l. Provide alternative means of communication.
m. Minimize external noise or distractions when communicating.

6. Impaired judgment

a. Remove throw rugs, toxic substances, and dangerous electrical appliances from the environment.
b. Reduce hot water heater temperature.

7. Altered thought processes

a. Call the client by name.
b. Orient the client frequently.
c. Use familiar objects in the room.
d. Place a calendar and clock in a visible place.
e. Maintain familiar routines.
f. Allow the client to reminisce.
g. Make tasks simple.
h. Allow time for the client to complete a task.
i. Provide positive reinforcement for positive behaviors.

8. Altered sleep patterns

a. Allow the client to wander in a safe place until she or he becomes tired.
b. Prevent shadows in the room by using indirect light.
c. Avoid the use of hypnotics because they cause confusion and aggravate the
sundown effect.

9. Agitation

a. Assess the precipitant of the agitation.
b. Reassure the client.
c. Remove items that can be hazardous when the client is agitated.
d. Approach the client slowly and calmly from the front, and speak, gesture, and move slowly.
e. Remove the client to a less stressful environment; decrease excess stimuli.
f. Use touch gently.
g. Do not argue with or force the client to do something.

Box 65-1
Criteria for General Anxiety Disorder

- Excessive anxiety and worry about several events or activities for more than 6 months
- Inability to cope with anxiety
- Anxiety associated with three (or more) of the following symptoms for more than 6 months:
  1. Feeling restless or on edge
  2. Easily tired
  3. Poor attention span
  4. Irritability
  5. Muscle tension
  6. Difficulty sleeping (insomnia, difficulty falling or staying asleep)
- Anxiety causes significant distress or impaired ability to work or maintain relationships
- No concurrent substance use or misuse
- No underlying medical cause
- Not explained by another mental health problem

Box 65-2
Interventions for Post-traumatic Stress Disorder

2277
• Be nonjudgmental and supportive.
• Assure the client that her or his feelings and behaviors are normal reactions.
• Assist the client to recognize the association between her or his feelings and behaviors and the trauma experience.
• Encourage the client to express her or his feelings; provide individual therapy that addresses loss of control or anger issues.
• Monitor for suicidal risk
• Teach stress management techniques.
• Assist the client to develop adaptive coping mechanisms and to use relaxation techniques.
• Encourage use of support groups.
• Facilitate a progressive review of the trauma experience (called flooding).
• Encourage the client to establish and re-establish relationships.
• Include the family in treatment.
• Inform the client that hypnotherapy or systematic desensitization may be recommended as a form of treatment.

Box 65-3
Some Types of Phobias

Acrophobia: Fear of heights
Agoraphobia: Fear of open spaces
Astraphobia: Fear of electrical storms
Claustrophobia: Fear of closed spaces
Hematophobia: Fear of blood
Hydrophobia: Fear of water
Monophobia: Fear of being alone
Mysophobia: Fear of dirt or germs
Nyctophobia: Fear of darkness
Pyrophobia: Fear of fires
Social Phobia: Fear of situations in which one might be embarrassed or criticized; fear of making a fool of oneself
Xenophobia: Fear of strangers
Zoophobia: Fear of animals

Box 65-4
Interventions for Obsessive-Compulsive and Related Disorders

• Ensure that basic needs (food, rest, hygiene) are met.
• Identify situations that precipitate compulsive behavior; encourage the client to verbalize concerns and feelings.

• Be empathetic toward the client and aware of her or his need to perform the compulsive behavior.

• Do not interrupt compulsive behaviors unless they jeopardize the safety of the client or others (provide for client safety related to the behavior).

• Allow time for the client to perform the compulsive behavior, but set limits on behaviors that may interfere with the client’s physical well-being to protect the client from physical harm.

• Implement a schedule for the client that distracts from the behaviors (structure simple activities, games, or tasks for the client).

• Establish a written contract that assists the client to decrease the frequency of compulsive behaviors gradually.

• Recognize and reinforce positive nonritualistic behaviors.

**Box 65-5**

**Assessment of Bipolar and Related Disorders**

**Mania**

• Becomes angry quickly
• Delusional self-confidence
• Constantly pushing limits, manipulating, and finding fault
• Euphoric with intense feelings of well-being
• Demonstrates little or no inhibition
• Distracted by environmental stimuli
• Extroverted personality
• Flight of ideas
• Grandiose and persecutory delusions
• High and unstable affect
• Significant decrease in appetite
• Inability to eat or sleep because of involvement in more important things
• Unlimited energy
• Inappropriate affect
• Dress that is inappropriately bizarre, loud, and/or colorful
• Makeup is colorful and overdone
• Excessive spending
• Pressured and/or clanging speech
• Restlessness
• Sexually promiscuous
• Urgent motor activity
Depression

- Increased or decreased appetite
- Decrease in activities of daily living
- Decreased emotion and physical activity
- Easily fatigued
- Inability to make decisions
- Poor concentration
- Internalizing hostility
- Introverted personality
- Social isolation and withdrawn from groups
- Lack of energy
- Lack of initiative
- Lack of self-confidence and low self-esteem
- Lack of sexual interest
- Psychomotor retardation
- Suicidal thinking

Box 65-6

Dealing with Inappropriate Behaviors Associated with Bipolar Disorder

Aggressive Behavior

- Assist the client in identifying feelings of frustration and aggression.
- Encourage the client to talk out instead of acting out feelings of frustration.
- Assist the client in identifying precipitating events or situations that lead to aggressive behavior.
- Describe the consequences of the behavior for self and others.
- Assist the client in identifying previous coping mechanisms.
- Assist the client in problem-solving techniques to cope with frustration or aggression.

De-escalation Techniques

- Maintain safety for the client, other clients, and self.
- Respect personal space and use a nonaggressive posture.
- Establish verbal contact.
- Use a calm approach and communicate with a calm, clear tone of voice (be assertive, not aggressive).
- Be concise.
• Determine what the client considers to be her or his wants and feelings.
• Listen closely to what the client is saying.
• Avoid verbal struggles: agree or agree to disagree.
• Provide the client with clear options that deal with the client’s behavior.
• Offer choices and optimism.
• Assist the client with problem solving and decision making regarding options.
• Debrief the client and staff.

Manipulative Behavior

• Set clear, consistent, realistic, and enforceable limits, and communicate expected behaviors.
• Be clear about consequences associated with exceeding set limits and follow through with consequences in a nonpunitive manner, if necessary.
• Discuss the client’s behavior in a nonjudgmental and nonthreatening manner.
• Avoid power struggles with the client (avoid arguing with the client).
• Assist the client in developing means of setting limits on own behavior.

Box 65-7

Interventions for Depressed Clients

Risk for Harm

• Assess for homicidal and suicidal ideation.
• Provide safety from suicidal actions (be certain that there are no harmful objects in the environment).
• Do not leave the client alone for extended periods.
• If the client has a suicidal plan, place on one-to-one supervision.
• Form a “no-suicide contract” with the client as appropriate.

Activities

• Use gentle encouragement to participate in activities of daily living and unit therapies.
• Do not push decision making or the making of complex choices or decisions that the client is not ready for.
• Provide achievable activities in which the client can achieve success (focus on strengths).
• Begin the client with one-to-one activities.
• Provide activities for easy mastery to increase self-esteem and help in alleviating guilt feelings and activities that do not require a great deal of concentration (simple card games, drawing).
- Engage the client in gross motor activities (walking).
- Eventually bring the client into small group activities and then into large groups.

**Nutrition**

- Monitor nutritional intake and weight and provide nutritional support.
- Stay with the client during meals to accurately assess intake and to assist in ensuring adequate nutritional intake.

**Hygiene Care**

- Monitor for general hygiene and self-care deficits; deficits may indicate worsening depression.
- Provide prompts to encourage activities of daily living.

**Sleep Patterns**

- Monitor sleep patterns.
- Decrease environmental stimuli at bedtime.
- Encourage relaxation techniques.
- Spend time with the client before bedtime to increase comfort and minimize feelings of loneliness and isolation.

**Altered Thought Processes**

- Remind the client of times when she or he felt better and was successful.
- Spend time with the client to convey the client’s worth and value.
- Encourage the client to discuss losses or changes in the life situation.
- Encourage the client to express sadness or anger and allow adequate time for verbal responses.
- Respond to anger therapeutically.

**Box 65-8**

**Electroconvulsive Therapy (ECT): Indications for Use**

- When antidepressant medications have no effect
- When there is a need for a rapid definitive response, such as when a client is suicidal or homicidal
- When the client is in extreme agitation or stupor
- When the risks of other treatments outweigh the risk of ECT
• When the client has a history of poor medication response, a history of good ECT response, or both
• When the client prefers ECT as a treatment

![Diagram of treatment-relevant dimensions of schizophrenia. LOA, Looseness of association.]

**FIG. 65-1** Treatment-relevant dimensions of schizophrenia. LOA, Looseness of association.

---

**Box 65-9**

**Abnormal Motor Behaviors**

**Description**

Abnormal motor behavior or activity displayed by a client with a mental health problem that occurs as a result of a mental health disorder

**Types**

*Echolalia*: Repeating the speech of another person
*Echopraxia*: Repeating the movements of another person
*Waxy Flexibility*: Having one’s arms or legs placed in a certain position and holding that same position for hours
## Abnormal Thought Processes

### Description

Abnormal thought processes displayed by a client with a mental health problem that occur as a result of a mental health disorder.

### Types

- **Circumstantiality:** Before getting to the point or answering a question, the client gets caught up in countless details and explanations.
- **Confabulation:** Filling a memory gap with detailed fantasy believed by the teller; the purpose of confabulation is to maintain self-esteem; seen in organic conditions such as Korsakoff’s psychosis.
- **Flight of Ideas:** Constant flow of speech in which the client jumps from one topic to another in rapid succession; a connection between topics exists, although it is sometimes difficult to identify; seen in manic states.
- **Looseness of Association:** Haphazard, illogical, and confused thinking and interrupted connections in thought; seen mostly in schizophrenic disorders.
- **Neologisms:** Client makes up words that have meaning only to the individual; often part of a delusional system.
- **Thought Blocking:** Sudden cessation of a thought in the middle of a sentence; client is unable to continue the train of thought; often, sudden new thoughts unrelated to the topic come up.
- **Word Salad:** Mixture of words and phrases that has no meaning.

## Box 65-11

### Delusions

### Description

A false belief held to be true, even when there is evidence to the contrary.

### Types

- **Grandeur:** False belief that one is a powerful and important person.
- **Jealousy:** False belief that one’s partner or mate is going out with other persons.
- **Persecution:** Thought that one is being singled out for harm by others.

### Interventions

- Ask the client to describe the delusion.
- Be open and honest in interactions to reduce suspiciousness.
- Focus conversation on reality-based topics, rather than on the delusion.
• Encourage the client to express feelings and focus on feelings that the delusions generate.
• If the client obsesses on the delusion, set firm limits on the amount of time spent talking about the delusion.
• Do not argue with the client or try to convince the client that the delusions are false.
• Validate if part of the delusion is real.

**Box 65-12**

**Hallucinations**

**Description**

Sense perception (occurs with 1 of the 5 senses) for which no external stimuli exist; can have an organic or functional cause

**Types**

- **Auditory:** Hearing voices when none are present
- **Gustatory:** Experiencing taste in the absence of stimuli
- **Olfactory:** Smelling smells that do not exist
- **Tactile:** Feeling touch sensations in the absence of stimuli
- **Visual:** Seeing things that are not there

**Interventions**

- Ask the client directly about the hallucination.
- Avoid reacting to the hallucination as if it were real.
- Decrease stimuli or move the client to another area.
- Do not negate the client’s experience.
- Focus on reality-based topics.
- Attempt to engage the client’s attention through a concrete activity.
- Respond verbally to anything real that the client talks about.
- Avoid touching the client.
- Monitor for signs of increasing anxiety or agitation, which may indicate that hallucinations are increasing.

**Box 65-13**

**Language and Communication Disturbances**
**Alogia (poverty of speech):** Reduced volume or lack of spontaneous comments and overly brief responses.

**Associative Looseness:** Disjointed mental threads that tie thoughts logically together.

**Clang Association:** Repetition of words or phrases that are similar in sound but in no other way

**Echolalia:** Repetition of words or phrases heard from another person

**Mutism:** Absence of verbal speech

**Neologism:** A newly devised word that has special meaning only to the client

**Pressured Speech:** Speaking as if the words are being forced out quickly

**Religiosity:** Excessive preoccupation with religious ideas.

**Tangentiality:** Digression from one topic to another without ever completing the thought or reaching a conclusion.

**Verbigeration:** Purposeless repetition of words or phrases

**Word Salad (Schizophasia):** Form of speech in which words or phrases are connected meaninglessly

---

**Box 65-14**

**Interventions for Schizophrenia**

- Maintain a safe environment.
- Set limits on the client’s behavior if the client is unable to do so, especially when it interferes with others and becomes disruptive.
- Assess the client’s physical needs.
- Initiate one-on-one interaction and progress to small groups as tolerated.
- Monitor for altered thought processes.
- Maintain ego boundaries and avoid touching the client.
- Avoid an overly warm approach; a neutral approach is less threatening.
- Do not make promises to the client that cannot be kept.
- Establish daily routines.
- Assist the client to improve grooming and accept responsibility for personal care.
- Provide brief, frequent contact with the client; limit time of interaction with the client.
- Tell the client when you are leaving.
- Tell the client when you do not understand what she or he is saying.
- Do not “go along” with the client’s delusions or hallucinations.
- Provide simple, concrete activities, such as puzzles or word games.
- Reorient the client as necessary.
- Help the client establish what is real and unreal.
- Stay with the client if she or he is frightened.
- Speak to the client in a simple, direct, and concise manner.
• Reassure the client that the environment is safe.
• Remove the client from group situations if the client’s behavior is too bizarre, disturbing, or dangerous to others.
• Set realistic goals.
  • Initially, do not offer choices to the client; then gradually assist the client in making her or his own decisions.
• Decrease excessive stimuli in the environment.
• Monitor for suicide risk.
• Assist the client to use alternative means to express feelings, such as through music, art therapy, or writing.

Box 65-15

Interventions for Paranoia

• Provide a safe environment.
• Assure the client that she or he will be safe.
• Assess for suicide risk.
• Diminish suspicious behavior, such as whispering.
• Remain calm, nonthreatening, and nonjudgmental.
• Engage the client during brief but frequent interactions.
• Establish a trusting relationship.
• Maintain physical boundaries and avoid crowding the client.
• Promote increased self-esteem.
• Respond honestly to the client.
• Follow through on commitments made to the client.
• Acknowledge the client’s feelings, but tell the client that you do not share her or his interpretation of an event.
• Provide a daily schedule of activities.
• Assist the client to identify diversionary activities.
• Gradually introduce the client to groups.
• Refocus conversation to reality-based topics.
• Use role playing to help the client identify thoughts and feelings.
• Provide positive reinforcement for successes.
• Do not argue with delusions.
• Do not whisper in the client’s presence.
• Provide the client with the opportunity to complete small tasks.
• Monitor eating, drinking, sleeping, and elimination patterns.
• Monitor for agitation, and decrease stimuli as needed.
**Box 65-16**

**Alzheimer’s Disease**

*Agnosia:* Failure to recognize or identify familiar objects despite intact sensory function  
*Amnesia:* Loss of memory caused by brain degeneration  
*Aphasia:* Language disturbance in understanding and expressing spoken words  
*Apraxia:* Inability to perform motor activities, despite intact motor function

**Practice Questions**

803. A client says to the nurse, “The federal guards were sent to kill me.” Which is the best response by the nurse to the client’s concern?  
1. “I don’t believe this is true.”  
2. “The guards are not out to kill you.”  
3. “Do you feel afraid that people are trying to hurt you?”  
4. “What makes you think the guards were sent to hurt you?”

804. A client diagnosed with delirium becomes disoriented and confused at night. Which intervention should the nurse implement initially?  
1. Move the client next to the nurses’ station.  
2. Use an indirect light source and turn off the television.  
3. Keep the television and a soft light on during the night.  
4. Play soft music during the night, and maintain a well-lit room.

805. A client is admitted to the mental health unit with a diagnosis of depression. The nurse should develop a plan of care for the client that includes which intervention?  
1. Encouraging quiet reading and writing for the first few days  
2. Identification of physical activities that will provide exercise  
3. No socializing activities until the client asks to participate in milieu  
4. A structured program of activities in which the client can participate

806. When planning the discharge of a client with chronic anxiety, which is the most appropriate maintenance goal?  
1. Suppressing feelings of anxiety  
2. Identifying anxiety-producing situations  
3. Continuing contact with a crisis counselor  
4. Eliminating all anxiety from daily situations

807. A client is unwilling to go to his church because his ex-girlfriend goes there and he feels that she will laugh at him if she sees him. Because of this hypersensitivity to a reaction from her, the client remains homebound. The home care nurse develops a plan of care that addresses which personality disorder?  
1. Avoidant  
2. Borderline  
3. Schizotypal
4. Obsessive-compulsive

808. The nurse is conducting a group therapy session. During the session, a client diagnosed with mania consistently disrupts the group’s interactions. Which intervention should the nurse initially implement?
1. Setting limits on the client’s behavior
2. Asking the client to leave the group session
3. Asking another nurse to escort the client out of the group session
4. Telling the client that they will not be able to attend any future group sessions

809. A client is admitted to a medical nursing unit with a diagnosis of acute blindness after being involved in a hit-and-run accident. When diagnostic testing cannot identify any organic reason why this client cannot see, a mental health consult is prescribed. The nurse plans care based on which mental health condition?
1. Psychosis
2. Repression
3. Conversion disorder
4. Dissociative disorder

810. A manic client begins to make sexual advances toward visitors in the dayroom. When the nurse firmly states that this is inappropriate and will not be allowed, the client becomes verbally abusive and threatens physical violence to the nurse. Based on the analysis of this situation, which intervention should the nurse implement?
1. Place the client in seclusion for 30 minutes.
2. Tell the client that the behavior is inappropriate.
3. Escort the client to their room, with the assistance of other staff.
4. Tell the client that their telephone privileges are revoked for 24 hours.

811. Which nursing interventions are appropriate for a hospitalized client with mania who is exhibiting manipulative behavior? Select all that apply.
1. Communicate expected behaviors to the client.
2. Ensure that the client knows that they are not in charge of the nursing unit.
3. Assist the client in identifying ways of setting limits on personal behaviors.
4. Follow through about the consequences of behavior in a nonpunitive manner.
5. Enforce rules by informing the client that he/she will not be allowed to attend therapy groups.
6. Have the client state the consequences for behaving in ways that are viewed as unacceptable.

812. The nurse observes that a client is pacing, agitated, and presenting aggressive gestures. The client’s speech pattern is rapid, and affect is belligerent. Based on these observations, which is the nurse’s immediate
priority of care?
1. Provide safety for the client and other clients on the unit.
2. Provide the clients on the unit with a sense of comfort and safety.
3. Assist the staff in caring for the client in a controlled environment.
4. Offer the client a less stimulating area in which to calm down and gain control.

813. The nurse is preparing a client with schizophrenia a history of command hallucinations for discharge by providing instructions on interventions for managing hallucinations and anxiety. Which statement in response to these instructions suggests to the nurse that the client has a need for additional information?
   1. “My medications will help my anxious feelings.”
   2. “I’ll go to support group and talk about what I am feeling.”
   3. “When I have command hallucinations, I’ll call a friend for help.”
   4. “I need to get enough sleep and eat well to help prevent feeling anxious.”

814. The nurse is caring for a client just admitted to the mental health unit and diagnosed with catatonic stupor. The client is lying on the bed in a fetal position. Which is the most appropriate nursing intervention?
   1. Ask direct questions to encourage talking.
   2. Leave the client alone so as to minimize external stimuli.
   3. Sit beside the client in silence with simple open-ended questions.
   4. Take the client into the dayroom with other clients to provide stimulation.

815. The nurse is caring for a client diagnosed with paranoid personality disorder who is experiencing disturbed thought processes. In formulating a nursing plan of care, which best intervention should the nurse include?
   1. Increase socialization of the client with peers.
   2. Avoid using a whisper voice in front of the client.
   3. Begin to educate the client about social supports in the community.
   4. Have the client sign a release of information to appropriate parties for assessment purposes.

816. The nurse is planning activities for a client diagnosed with bipolar disorder with aggressive social behavior. Which activity would be most appropriate for this client?
   1. Chess
   2. Writing
   3. Board games
   4. Group exercise

Answers

803. Answer: 3

Rationale: It is most therapeutic for the nurse to empathize with the client’s experience. The remaining options lack this connection with the client. Disagreeing
with delusions may make the client more defensive, and the client may cling to the delusions even more. Encouraging discussion regarding the delusion is inappropriate.

**Test-Taking Strategy:** Note the **strategic word**, best. Use therapeutic communication techniques. Eliminate options that show disagreement with the client or encourage any discussion regarding the delusion.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Communication and Documentation

**Content Area:** Mental Health

**Health Problem:** Mental Health: Therapeutic Communication

**Priority Concepts:** Communication; Psychosis

804. **Answer:** 2

**Rationale:** Provision of a consistent daily routine and a low-stimulating environment is important when a client is disoriented. Noise, including radio and television, may add to the confusion and disorientation. Moving the client next to the nurses’ station may become necessary but is not the initial action.

**Test-Taking Strategy:** Note the **strategic word**, initially. Eliminate options that are inappropriate or premature actions and may increase stimulation and add to the confusion. This will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Mental Health

**Health Problem:** Mental Health: Neurocognitive Impairment

**Priority Concepts:** Cognition; Safety

**Reference:** Varcarolis (2017), pp. 275, 277.

805. **Answer:** 4

**Rationale:** A client with depression often is withdrawn while experiencing difficulty concentrating, loss of interest or pleasure, low energy, fatigue, and feelings of worthlessness and poor self-esteem. The plan of care needs to provide successful experiences in a stimulating yet structured environment. The remaining options are either too “restrictive” or offer little or no structure and stimulation.

**Test-Taking Strategy:** Focus on the **subject**, the plan for a client with depression. Recall that a depressed client requires a structured and stimulating program in a safe environment. The correct option is the only one that will provide a safe and effective environment.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Nursing Process—Planning

**Content Area:** Mental Health

**Health Problem:** Mental Health: Mood Disorders
**Priority Concepts:** Mood and Affect; Safety

806. **Answer:** 2

**Rationale:** Recognizing situations that produce anxiety allows the client to prepare to cope with anxiety or avoid a specific stimulus. Counselors will not be available for all anxiety-producing situations, and this option does not encourage the development of internal strengths. Suppressing feelings will not resolve anxiety. Elimination of all anxiety from life is impossible.

**Test-Taking Strategy:** Focus on the **strategic words, most appropriate.** Eliminate any option that contains the **closed-ended word “all”** or suggests that feelings should be suppressed. Note that the correct option is more client-centered and helps prepare the client to deal with anxiety should it occur.

**Level of Cognitive Ability:** Applying

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Planning

**Content Area:** Mental Health

**Health Problem:** Mental Health: Anxiety Disorder

**Priority Concepts:** Anxiety; Health Promotion

807. **Answer:** 1

**Rationale:** The avoidant personality disorder is characterized by social withdrawal and extreme sensitivity to potential rejection. The person retreats to social isolation. Borderline personality disorder is characterized by unstable mood and self-image and impulsive and unpredictable behavior. Schizotypal personality disorder is characterized by the display of abnormal thoughts, perceptions, speech, and behaviors. Obsessive-compulsive personality disorder is characterized by perfectionism, the need to control others, and a devotion to work.

**Test-Taking Strategy:** Focus on the **subject, a type of personality disorder.** Focusing on the words **hypersensitivity to a reaction** will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Nursing Process—Planning

**Content Area:** Mental Health

**Health Problem:** Mental Health: Personality Disorders

**Priority Concepts:** Anxiety; Caregiving

808. **Answer:** 1

**Rationale:** Manic clients may be talkative and can dominate group meetings or therapy sessions by their excessive talking. If this occurs, the nurse initially would set limits on the client’s behavior. Initially, asking the client to leave the session or
asking another person to escort the client out of the session is inappropriate. This may agitate the client and escalate the client’s behavior further. Barring the client from group sessions is also an inappropriate action because it violates the client’s right to receive treatment and is a threatening action.

**Test-Taking Strategy:** Note the **strategic word**, *initially*. Eliminate options that are comparable or alike and relate to the client leaving the session. Next, eliminate the option that violates the client’s right to receive treatment and is a threatening action. Remember that setting firm limits with the client initially is best.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Mood Disorders  
**Priority Concepts:** Caregiving; Psychosis  

809. **Answer:** 3

**Rationale:** A conversion disorder is the alteration or loss of a physical function that cannot be explained by any known pathophysiological mechanism. A conversion disorder is thought to be an expression of a psychological need or conflict. In this situation, the client witnessed an accident that was so psychologically painful that the client became blind. Psychosis is a state in which a person’s mental capacity to recognize reality, communicate, and relate to others is impaired, interfering with the person’s ability to deal with life’s demands. Repression is a coping mechanism in which unacceptable feelings are kept out of awareness. A dissociative disorder is a disturbance or alteration in the normally integrative functions of identity, memory, or consciousness.

**Test-Taking Strategy:** Focus on the **subject**, the cause of acute blindness. The key to the correct option lies in the fact that the client presents no organic reason to account for the blindness—hence, a conversion disorder.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Somatization disorder  
**Priority Concepts:** Caregiving; Psychosis  

810. **Answer:** 3

**Rationale:** The client is at risk for injury to self and others and should be escorted out of the dayroom. Seclusion is premature in this situation. Telling the client that the behavior is inappropriate has already been attempted by the nurse. Denying privileges may increase the agitation that already exists in this client.

**Test-Taking Strategy:** Eliminate option 2 because this intervention has already been attempted. Next, use **Maslow’s Hierarchy of Needs theory** to answer the
question. Remember that if a physiological need is not present, focus on safety. Look for the option that promotes safety of the client, other clients, and staff.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Safe and Effective Care Environment  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Violence  
**Priority Concepts:** Mood and Affect; Safety  

811. **Answer:** 1, 3, 4, 6

**Rationale:** Interventions for dealing with the client exhibiting manipulative behavior include setting clear, consistent, and enforceable limits on manipulative behaviors; being clear with the client regarding the consequences of exceeding the limits set; following through with the consequences in a nonpunitive manner; and assisting the client in identifying a means of setting limits on personal behaviors. Ensuring that the client knows that she or he is not in charge of the nursing unit is inappropriate; power struggles need to be avoided. Enforcing rules and informing the client that she or he will not be allowed to attend therapy groups is a violation of a client’s rights.

**Test-Taking Strategy:** Focus on the subject, manipulative behavior. Recalling clients’ rights and that power struggles need to be avoided will assist in selecting the correct interventions.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Mood Disorders  
**Priority Concepts:** Clinical Judgment; Mood and Affect  

812. **Answer:** 1

**Rationale:** Safety of the client and other clients is the immediate priority. The correct option is the only one that addresses the safety needs of the client as well as those of the other clients.

**Test-Taking Strategy:** Note the **strategic words**, *immediate priority*, and use **Maslow’s Hierarchy of Needs theory** to prioritize. Note the words *agitated, aggressive, and belligerent*. Safety is the priority focus if a physiological need does not exist. Also, the correct option is the *umbrella option* and addresses the safety of all.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Safe and Effective Care Environment  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Violence  
**Priority Concepts:** Mood and Affect; Safety

813. Answer: 3

Rationale: The risk for impulsive and aggressive behavior may increase if a client is receiving command hallucinations to harm self or others. If the client is experiencing a hallucination, the nurse or health care counselor, not a friend, should be contacted to discuss whether the client has intentions to hurt herself or himself or others. Talking about auditory hallucinations can interfere with subvocal muscular activity associated with a hallucination. The client statements in the remaining options will aid in wellness but are not specific interventions for hallucinations, if they occur.

Test-Taking Strategy: Note the strategic words, need for additional information. These words indicate a negative event query and the need to select the incorrect statement as the answer. Focus on the subject, managing hallucinations and anxiety. The correct option is a specific agreement to seek appropriate help. The remaining options are interventions that a client can carry out to aid wellness.

Level of Cognitive Ability: Evaluating
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Teaching and Learning
Content Area: Mental Health
Health Problem: Mental Health: Schizophrenia
Priority Concepts: Client Education; Safety

814. Answer: 3

Rationale: Clients who are withdrawn may be immobile and mute and may require consistent, repeated approaches. Communication with withdrawn clients requires much patience from the nurse. Interventions include the establishment of interpersonal contact. The nurse facilitates communication with the client by sitting in silence, asking simple open-ended questions rather than direct questions, and pausing to provide opportunities for the client to respond. Although overstimulation is not appropriate, there is no therapeutic value in ignoring the client. The client’s safety is not the responsibility of other clients.

Test-Taking Strategy: Note the strategic words, most appropriate. Eliminate options either that are nontherapeutic or could result in overstimulation. Also eliminate options that are not examples of therapeutic communication. The correct option provides for client supervision and communication as appropriate.

Level of Cognitive Ability: Applying
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Mental Health
Health Problem: Mental Health: Schizophrenia
Priority Concepts: Caregiving; Psychosis
**Rationale:** Disturbed thought process related to paranoid personality disorder is the client’s problem, and the plan of care must address this problem. The client is distrustful and suspicious of others. The members of the health care team need to establish a rapport and trust with the client. Laughing or whispering in front of the client would be counterproductive. The remaining options ask the client to trust on a multitude of levels. These options are actions that are too intrusive for a client with this disorder.

**Test-Taking Strategy:** Focus on the subject, interventions for paranoid personality disorder, and note the strategic word, best. Note that the client has paranoia; thinking about its definition will direct you to the correct option.

**Level of Cognitive Ability:** Applying
**Client Needs:** Psychosocial Integrity
**Integrated Process:** Nursing Process—Implementation
**Content Area:** Mental Health
**Health Problem:** Mental Health: Personality Disorders
**Priority Concepts:** Caregiving; Psychosis

---

816. **Answer:** 2

**Rationale:** Solitary activities that require a short attention span with mild physical exertion are the most appropriate activities for a client who is exhibiting aggressive behavior. Writing (journaling), walks with staff, and finger painting are activities that minimize stimuli and provide a constructive release for tension. The remaining options have a competitive element to them or are group activities and should be avoided because they can stimulate aggression and increase psychomotor activity.

**Test-Taking Strategy:** Note the strategic words, most appropriate. Eliminate options that include activities that the client cannot do alone and are competitive in nature. The correct option identifies a solitary activity.

**Level of Cognitive Ability:** Applying
**Client Needs:** Physiological Integrity
**Integrated Process:** Nursing Process—Planning
**Content Area:** Mental Health
**Health Problem:** Mental Health: Mood Disorders
**Priority Concepts:** Mood and Affect; Safety
CHAPTER 66

Addictions

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Addiction; Coping

I. Eating Disorders
   A. Description: Eating disorders are characterized by unsure self-identification and grossly disturbed eating habits (Fig. 66-1).
   B. Compulsive overeating
      1. Compulsive overeating is binge-like overeating without purging.
      2. Food consumption is out of the individual’s control and occurs in a stereotyped fashion.
      3. Repulsed by eating, that is, the eating relieves tension but does not produce pleasure.
      4. Aware that eating patterns are abnormal and feels depressed after eating.
      5. Eats secretly during a binge and consumes high-calorie and easily digestible food.
      6. Repeatedly tries to diet, but without success.
      7. Feels helpless and hopeless about weight.
      8. Responds to feelings of guilt, anger, depression, boredom, loneliness, inadequacy, or ambivalence by eating.
   C. Anorexia nervosa
      1. Description
         a. Onset often is associated with a stressful life event.
         b. Intensely fears obesity.
         c. Body image is distorted and a disturbed self-concept is common.
         d. Preoccupied with foods that prevent weight gain and has a phobia against foods that produce weight gain.
         e. The eating disorder can be life-threatening.
f. Death can occur from starvation, suicide, cardiomyopathies, or electrolyte imbalances.

2. Assessment
   a. Appetite loss and refusal to eat
   b. Appetite denial
   c. Feelings of lack of control
   d. Compulsive exercising
   e. Overachiever and perfectionist
   f. Physical alterations: Many occur and can include decreased temperature, pulse, and blood pressure; weight loss; gastrointestinal disturbances such as constipation; teeth and gum deterioration; esophageal varices from induced vomiting; electrolyte imbalances; dry, scaly skin; presence of lanugo on extremities; sleep disturbances; hormone deficiencies; amenorrhea for at least 3 consecutive menstrual periods; cyanosis and numbness of extremities; and bone degeneration.

D. Bulimia nervosa
   1. Description
      a. Repeated episodes of excessive and uncontrollable consumption of large amounts of food (binges) followed by inappropriate compensatory actions such as self-induced vomiting, misuse of cathartics (e.g., laxatives), diuretics, and/or self-starvation
      b. Most clients remain within a normal weight range, but think that their lives are dominated by the eating-related conflict.

   2. Assessment
      a. Preoccupied with body shape and weight
      b. Preoccupation with thoughts of food
      c. Extreme fear of gaining weight
      d. Consumption of high-calorie food in secret; guilt about secretive eating
e. Binge-purge syndrome
f. Attempts to lose weight through diets, vomiting, enemas, cathartics, and amphetamines or diuretics
g. Assess nutritional status and the severity of any medical problems.
h. Has a need to control, yet experiences feelings of powerlessness or loss of control
i. Low self-esteem
j. Poor interpersonal relationships
k. Decreased interest, or absence of interest, in sex
l. Mood swings
m. Electrolyte imbalances
n. Physical alterations: Similar to those that occur with anorexia nervosa
o. Important questions to ask is about their perception of the problem and eating habits

E. Interventions: Clients with an eating disorder

1. Establish a one-to-one therapeutic relationship with the client; the nurse needs to establish trust and recognize any client reluctance to establish a relationship.
2. Establish a plan concerning the nutritional plan for the day.
3. Assist to identify precipitants to the eating disorder.
4. Encourage the client to express feelings about the eating behavior and how the client feels about her or his body.
5. Be accepting and nonjudgmental.
7. Implement behavior modification techniques.
8. Individual, group, and family therapy
9. If in a health care facility, supervise during mealtimes and for a specified period after meals and monitor intake and output; set a time limit for each meal and provide a pleasant, relaxed environment for eating.
10. Monitor for signs of physical complications related to the eating disorder.
11. When a client’s weight is below 75% of ideal body weight, provide immediate medical stabilization as an inpatient.
12. Weigh daily at the same time, using the same scale, after the client voids (weighing each day may decrease anxiety in some clients); when weighing the client, ensure that the client is wearing the same clothing as when the previous weight was taken.
15. Assess and limit the client’s activity level (anorexia nervosa and bulimia nervosa).
16. Encourage the client to participate in diversional activities.
17. Assess suicide potential.
18. Administer antidepressant medication if prescribed.
19. Encourage psychotherapy.

II. Substance Use Disorders
A. Description: Substance use disorders (addiction) cause behavioral and physiological changes (Box 66-1).

B. Substance dependence
1. Substance dependence is a pattern of repeated use of a substance, which usually results in tolerance, withdrawal symptoms, and compulsive drug-taking behavior.
2. Substances are taken in larger amounts and over longer periods than was intended.
3. There is a desire to cut down, but efforts to decrease or discontinue use are unsuccessful.
4. Daily activities revolve around the use of a substance.

C. Substance tolerance is the need for increased amounts of the substance to achieve the desired effect.
D. Substance misuse
1. Uses substances recurrently
2. Recurrent, significant harmful consequences related to the use of substances are experienced.
3. Involvement with the legal system is common; the client may have legal issues to deal with and resolve.
E. Substance withdrawal
1. Physiological and substance-specific cognitive symptoms occur.
2. Substance withdrawal occurs when an individual experiences a decrease in blood levels of a substance on which the individual is physiologically
dependent.

F. Other factors to consider in a client with a substance-related disorder

1. Rebellion and peer group pressure in adolescence may contribute to the onset of substance use.
2. Substance use may become a coping mechanism used to decrease physical and emotional pain.
3. Depression may precede or occur as a result of or in association with substance use.
4. Grief and loss may be associated with substance use.

G. Dysfunctional behaviors related to substance misuse

1. Preoccupation with obtaining and using substance
2. Manipulation to avoid consequences of behavior
3. Impulsiveness
4. Anger, including physical and verbal abuse
5. Avoidance of relationships outside the family unit
6. Relationships within the family become dysfunctional as the children take on atypical roles to protect the family unit.
7. Sense of self-importance and requiring special treatment
8. Denial—blaming everything but the substance use for problems
9. Use of rationalization and projection to justify unacceptable behavior
10. Low self-esteem
11. Depression
12. Codependency issues

   a. Codependency refers to the presence of coexisting behaviors present in a significant other, which serves to enable the addict or alcoholic to continue the irresponsible patterns of use without experiencing consequences.

   b. Examples of codependency: Paying bills for which the addict or alcoholic is responsible, bailing the addict or alcoholic out of jail, and helping the addict or alcoholic call in sick to employment agency.

   c. It is important to address codependency issues with the family to maximize the chance for recovery of the client with the addiction and the person with the codependent behaviors.

III. Alcohol Misuse
A. Description
1. Alcohol is a central nervous system (CNS) depressant affecting all body tissues.
2. Physical dependence is a biological need for alcohol to avoid physical withdrawal symptoms, whereas psychological dependence refers to craving for the subjective effect of alcohol.

B. Risk factors
1. Biological predisposition; genetic and familial predisposition may also be a risk factor.
2. Depressed and highly anxious characteristics
3. Low self-esteem
4. Poor self-control
5. History of rebelliousness, poor school performance, and delinquency
6. Poor parental relationships

C. Assessment
1. Slurred speech
2. Uncoordinated movements
3. Unsteady gait
4. Restlessness
5. Confusion
6. Sneaking drinks, drinking in the morning, and experiencing blackouts
7. Binge drinking
8. Arguments about drinking
9. Missing work
10. Increased tolerance to alcohol
11. Intoxication, with blood alcohol content (BAC) of 0.1% (100 mg alcohol/dL blood) or greater (legal BAC may vary state to state)

Part of the assessment should include the type of alcohol, how much, for how long, and when last consumed.

D. Psychological symptoms
1. Depression
2. Irritable, belligerent, and hostile
3. Suspiciousness
4. Rationalization
5. Isolation
6. Decrease in inhibitions
7. Decrease in self-esteem
8. Denial that a problem exists

E. Complications associated with chronic alcohol use
1. Vitamin deficiencies
   a. Vitamin B deficiency causing peripheral neuropathies
   b. Thiamine deficiency, causing Korsakoff’s syndrome
2. Alcohol-induced persistent amnesic disorder, causing severe memory problems
3. Wernicke’s encephalopathy, causing confusion, ataxia, and abnormal eye movements
4. Hepatitis; cirrhosis of the liver
5. Esophagitis and gastritis
6. Pancreatitis
7. Anemias
8. Immune system dysfunctions
9. Brain damage
10. Peripheral neuropathy
11. Cardiac problems

IV. Alcohol Withdrawal
   A. Description
   1. Early signs develop within a few hours after cessation of alcohol intake.
   2. These signs peak after 24 to 48 hours and then rapidly disappear, unless the withdrawal progresses to alcohol withdrawal delirium.
   3. At the onset of withdrawal (Box 66-2), follow unit or agency protocol using specified withdrawal assessment scales.
   4. Chlordiazepoxide may be prescribed for acute alcohol withdrawal and is usually given orally, unless a more immediate onset is required (benzodiazepine medications would decrease the withdrawal symptoms because of cross-tolerance; see Chapter 68 for a list of benzodiazepines).
   5. An intramuscular injection of vitamin B₃ (thiamine) followed by several days of oral administration is usually prescribed to prevent Wernicke’s encephalopathy.

B. Withdrawal (see Box 66-2)

C. Delirium tremens: The state of delirium usually peaks 48 to 72 hours after cessation or reduction of intake (although it can occur later) and lasts 2 to 3 days (Box 66-3).

Withdrawal delirium is a medical emergency. Death can occur from myocardial infarction, fat emboli, peripheral vascular collapse, electrolyte imbalance, aspiration pneumonia, or suicide.
D. Interventions

1. Provide care in a nonjudgmental manner.
2. Check the client frequently.
3. Monitor vital signs and neurological signs (every 15 minutes) and provide one-to-one supervision.
4. Monitor serum electrolytes, including glucose and magnesium.
5. Provide a quiet, nonstimulating environment; encourage a family member (1 at a time) to stay with the client to minimize anxiety.
6. Orient frequently.
7. Explain all treatments and procedures in a quiet and simple manner.
8. Initiate seizure precautions.
9. Large amounts of benzodiazepine sedatives may be required to achieve adequate control of symptoms.
10. Provide small, frequent, high-carbohydrate foods (administer antiemetic before meals as needed).
11. Monitor intake and output.
12. Administer vitamins (multivitamin, vitamin B complex including thiamine, folic acid, and vitamin C).
13. Administer magnesium if hypomagnesia is present.
15. Allow client to express fears.

E. Medication therapy for alcohol misuse and alcohol dependence

1. Description: Medication is prescribed only for those individuals who have stopped drinking.
2. Naltrexone: Works by blocking in the brain the “high” feeling that people experience when they drink alcohol
3. Acamprosate: Works by reducing the physical distress and emotional discomfort people usually experience when they quit drinking
4. Disulfiram: Works by causing a severe adverse reaction when someone taking the medication consumes alcohol

F. Disulfiram therapy

1. Description
   a. The client must abstain from alcohol for at least 12 hours before the initial dose is administered.
   b. Adverse effects usually begin within several minutes to 30 minutes after consuming alcohol and may last 30 minutes to 2 hours.
   c. The client must avoid drinking alcohol
for 14 days after disulfiram therapy has been discontinued; otherwise, the client is at risk for a disulfiram-alcohol reaction.

2. Adverse effects
   a. Fatigue
   b. Facial flushing
   c. Sweating
   d. Throbbing headache
   e. Neck pain
   f. Nausea and vomiting
   g. Hypotension
   h. Tachycardia
   i. Respiratory distress

3. Client education
   a. Educate about the effects of the medication.
   b. Ensure agreement to abstain from alcohol and any alcohol-containing substances.
   c. Inform the client that effects of the medication may occur for several days after it is discontinued.

G. Managing the client who has a substance misuse disorder
(Boxes 66-4 and 66-5)

Instruct the client who is on disulfiram therapy to avoid the use of substances that contain alcohol, such as cough medicines, rubbing compounds, vinegar, mouthwashes, and aftershave lotions. The client needs to read the labels of all products.

V. Drug Dependency
   A. CNS depressants
      1. CNS depressants include alcohol, benzodiazepines, and barbiturates and act as a depressant, sedative, or hypnotic.
      2. Intoxication (Box 66-6)
      3. Overdose can produce cardiovascular or respiratory depression, coma, shock, seizures, and death.
      4. Overdose: If the client is awake, vomiting is induced and activated charcoal is administered; if the client is comatose, establishment and maintenance of an airway and gastric lavage with activated charcoal are the priorities; seizure precautions are indicated.
      5. Flumazenil intravenously may be used for
benzodiazepine overdose to reverse the effects.

6. Withdrawal effects include nausea, vomiting, tachycardia, diaphoresis, irritability, tremors, insomnia, and seizures; withdrawal must be treated with a carefully titrated similar drug (abrupt withdrawal can lead to death).

7. Withdrawal from CNS depressants such as barbiturates is generally treated with a barbiturate such as phenobarbital or a long-acting benzodiazepine.

B. CNS stimulants

1. CNS stimulants include substances such as amphetamines, cocaine, and crack.

2. Intoxication (Box 66-7)

3. Overdose can produce respiratory distress, ataxia, hyperpyrexia, seizures, coma, stroke, myocardial infarction, and death.

4. Overdose is treated with antipsychotics and management of associated effects.

5. Withdrawal effects include fatigue, depression, agitation, apathy, anxiety, insomnia, disorientation, lethargy, and craving.

6. Withdrawal is treated with antidepressants, a dopamine agonist, or bromocriptine; withdrawal is primarily supportive, particularly when dealing with the severe depression and suicidal ideation that accompanies stimulant withdrawal.

C. Opioids

1. Opioids include substances such as opium, heroin, meperidine, morphine, codeine sulfate, methadone, hydromorphone, oxycodone, hydrocodone, and fentanyl.

2. Intoxication (Box 66-8)

3. Overdose can produce respiratory depression, shock, coma, seizures, and death.

4. Overdose is treated with an opioid antagonist such as naloxone.

5. Withdrawal effects include yawning, insomnia, irritability, rhinorrhea, diaphoresis, cramps, nausea and vomiting, muscle aches, chills, fever, lacrimation, and diarrhea.

6. Withdrawal may be treated by methadone detoxification or tapering dosage with other opioids.

7. Clonidine, an α-adrenergic blocker, assists in reducing the severity of sympathetic nervous system–
generated withdrawal discomfort.

8. Specific measures for symptom management may also be used, such as antidiarrheal agents and acetaminophen for muscle aches.

D. Hallucinogens

1. Hallucinogens include substances such as lysergic acid diethylamide (LSD), mescaline (peyote), psilocybin (mushrooms), and phencyclidine (PCP).

2. Intoxication (Box 66-9)

3. Overdose effects of LSD, peyote, and psilocybin include psychosis, brain damage, and death; effects of PCP include psychosis, hypertensive crisis, hyperthermia, seizures, and respiratory arrest.

4. Treatment (LSD, peyote, psilocybin) involves low environmental stimuli (speak slowly, clearly, and in a low voice) and medications to treat anxiety.

5. Treatment (PCP) involves possible gastric lavage (if alert); treatment to acidify the urine to assist in excreting the drug; and interventions to treat behavioral disturbances, hyperthermia, hypertension, and respiratory distress.

6. Management of withdrawal is primarily supportive and may include medications to target particular problem behaviors, such as agitation.

Flashbacks, which are unexpected reexperiences of the effects of taking a hallucinogenic drug, can occur for extended periods of time after its original use. Safety during flashbacks is a priority.

E. Inhalants

1. Inhalants include gases or liquids such as butane, paint thinner, paint and wax removers, airplane glue, nail polish remover, and nitrous oxide.

2. Intoxication (Box 66-10)

3. Overdose can cause damage to the nervous system and death.

4. Management of withdrawal is mainly supportive, including the treatment of affected body systems.

F. Marijuana (Cannabis sativa)

1. Generally is smoked, but can be ingested; may be legally prescribed in certain states and in some states and provinces is legal without a prescription.

2. Causes euphoria, detachment, relaxation, talkativeness, slowed perception of time, anxiety, and paranoia.
3. Long-term dependence can result in lethargy, amotivation syndrome, difficulty concentrating, memory loss, and possibly chronic respiratory problems.

4. Withdrawal management is mainly supportive.

G. Other recreational and club drugs

There are many types of illegal street drugs that are harmful. The nurse needs to be knowledgeable about the physiological effects of these various drugs, be able to recognize the signs associated with their use, and be prepared to provide immediate treatment.

1. Can include methylenedioxymethamphetamine (MDMA, ecstasy), γ-hydroxybutyrate (GHB), methamphetamine (crank, meth, crystal meth), and ketamine (special K)
2. Effects include euphoria, increased energy, increased self-confidence, and increased sociability.
3. Adverse effects include hyperthermia, rhabdomyolysis, kidney failure, hepatotoxicity, depression, panic attacks, psychosis, cardiovascular collapse, and death.
4. Programs for addiction also address nicotine withdrawal and the pharmacological and psychotherapeutic interventions for this problem, such as nicotine patches, nicotine inhalers, and bupropion for the reduction of withdrawal symptoms and cravings.
5. Anabolic steroids have also gained increased attention as increasingly adverse events, including death, have become more widely publicized.

H. Interventions: Withdrawal (Box 66-11)

1. Initiate seizure precautions.
2. Hydrate the client.
3. Monitor vital signs every hour; include cardiac monitoring and diagnostic tests such as electrocardiogram and cardiac markers because of the risk of cardiac damage with certain drugs.
4. Monitor intake and output.
5. Orient the client frequently.
7. Approach the client in an accepting and nonjudgmental manner.
8. Direct focus to the substance misuse problem.
9. Assist the client with identifying situations that precipitate angry feelings.
10. Assist the client to deal with emotions.
11. Limit placing blame or rationalizing to explain the substance misuse problem.
12. Assist the client to use assertive techniques rather than manipulation to meet needs.
13. Set limits on manipulative behavior and verbal and physical misuse.
15. Hold the client accountable for all behaviors.
16. Assist the client to explore strengths and weaknesses.
17. Encourage the client to focus on strengths if the client is losing control.
18. Encourage the client to participate in unit activities.
19. Encourage the client to participate in group therapy and support groups.

I. Dual diagnoses
1. Sometimes the use of alcohol and drugs masks underlying psychiatric pathology.
2. Psychiatric pathology may also be precipitated by substance use and misuse.
3. When psychiatric disorders and substance misuse are present together, it is often referred to as dual diagnosis.
4. Separating psychiatric diagnosis from substance dependence can be done only over time after a sustained period of abstinence.

J. Addiction and substance misuse in health care professionals: Suspicious signs
1. Frequently reporting that drugs have been wasted without being witnessed by another nurse
2. Reporting administering maximum dosages of controlled substances to clients when other nurses do not administer the maximum dose
3. A variance in usual pain relief in the absence of a change in dosage or frequency of administration in their clients
4. Work patterns include the following: Always volunteering to carry narcotic (opioids) keys (or other opioid access devices per agency procedure); choosing shifts in which less supervision is present; choosing work areas where the use of controlled substances is high, such as critical care units, operating room, anesthesia, and trauma units
5. Nurses have a professional and ethical obligation to report impaired co-workers.
6. Most impaired nurses are able to return to work
through the State Board of Nursing assistance and monitoring programs; such programs usually require strict adherence to clearly stated rules and regular reports and drug screens.

**Box 66-1**

**CAGE Screening Questionnaire**

C Have you ever felt the need to cut down on your drinking/drug use?
A Have you ever been annoyed at criticism of your drinking/drug use?
G Have you ever felt guilty about something that you have done when you have been drinking or taking drugs?
E Have you ever had an eye opener—drinking or taking drugs first thing in the morning to get going or to avoid withdrawal symptoms?

**Box 66-2**

**Early Signs of Alcohol Withdrawal**

- Anorexia (nausea and vomiting may occur)
- Anxiety
- Easily startled
- Hyperalertness
- Hypertension
- Insomnia
- Irritability
- Jerky movements
- Possibly experiences hallucinations, illusions, delusions, or vivid nightmares
- Possibly reports a feeling of “shaking inside”
- Seizures (usually appear 7 to 48 hours after cessation of alcohol)
- Tachycardia
- Tremors

**Box 66-3**

**Manifestations of Alcohol Withdrawal Delirium (Delirium Tremens)**

- Agitation
- Anorexia
- Anxiety
- Delirium
- Diaphoresis
- Disorientation with fluctuating levels of consciousness
- Fever (temperature of 100° F [37.8° C] to 103° F [39.4° C])
- Hallucinations and delusions
- Insomnia
- Tachycardia and hypertension

**Box 66-4**

**Managing the Client Who Misuses Alcohol**

- Direct the client’s focus to the substance misuse problem.
- Identify situations that precipitate angry feelings with the client.
- Set limits on manipulative behavior and verbal and physical abuse.
- Hold the client firmly accountable to reasonable limits, consistently reinforcing rules, with reasonable consequences for breaking rules.
- Hold the client accountable for all behaviors.
- Use motivational interviewing to assist the client to explore strengths and weaknesses.
• Encourage the client to focus on strengths if the client is losing control.
• Encourage the client to participate in group therapy and support groups.

**Box 66-5**

**Therapies for Clients with Substance Misuse and for Their Families**

- Behavior therapy (including cognitive behavioral therapy [CBT]), aversion conditioning with medication
- Hospitalization
- Psychotherapy (individual, group, family)
- 12-Step support groups such as Alcoholics Anonymous; Narcotics Anonymous; Pills Anonymous; Al-Anon, Al-a-Teen, or Narc-Anon (for family members and friends of alcoholics or addicts); and Adult Children of Alcoholics
- Transitional living programs (halfway houses)

**Box 66-6**

**Intoxication: Central Nervous System Depressants**

- Drowsiness
- Hypotension
- Impairment of memory, attention, judgment, and social or occupational functioning
- Incoordination and unsteady gait
- Irritability
- Slurred speech
- Impotence

**Box 66-7**

**Intoxication: Central Nervous System Stimulants**

- Dilated pupils
- Euphoria
- Hypertension
- Impairment of judgment and social or occupational functioning
- Insomnia
- Nausea and vomiting
• Paranoia, delusions, hallucinations
• Potential for violence
• Tachycardia

**Box 66-8**

**Intoxication: Opioids**

• Constricted pupils
• Decreased respirations
• Drowsiness
• Euphoria
• Hypotension
• Impairment of memory, attention, and judgment
• Psychomotor retardation
• Slurred speech

**Box 66-9**

**Intoxication: Hallucinogens**

• Agitation and belligerence
• Anxiety and depression
• Bizarre behavior, regressive behavior, or violent behavior
• Blank stare
• Diaphoresis
• Dilated pupils
• Elevated vital signs, including blood pressure
• Hallucinations
• Impairment of judgment and social and occupational functioning
• Incoordination
• Muscular rigidity and chronic jerking
• Paranoia
• Seizures
• Tachycardia
• Tremors

**Box 66-10**

• 2313
Intoxication: Inhalants

▪ Enhancement of sexual pleasure
▪ Euphoria
▪ Excitation followed by drowsiness, lightheadedness, disinhibition, and agitation
▪ Giggling and laughter

Box 66-11
Withdrawal: Nursing Care

▪ Obtain information regarding the type of drug and amount consumed.
▪ Assess vital signs.
▪ Remove unnecessary objects from the environment.
▪ Provide one-to-one supervision if necessary.
▪ Provide a quiet, calm environment with minimal stimuli.
▪ Maintain client orientation.
▪ Ensure the client’s safety by implementing seizure precautions.
▪ Use security devices if necessary and as prescribed to prevent the client from harming self and others.
▪ Provide for physical needs.
▪ Provide food and fluids as tolerated.
▪ Administer medications as prescribed to decrease withdrawal symptoms.
▪ Collect blood and urine samples for drug screening.

Practice Questions

817. The home health nurse visits a client at home and determines that the client is dependent on drugs. During the assessment, which action should the nurse take to plan appropriate nursing care?
   1. Ask the client why he started taking illegal drugs.
   2. Ask the client about the amount of drug use and its effect.
   3. Ask the client how long he thought that he could take drugs without someone finding out.
   4. Do not ask any questions for fear that the client is in denial and will throw the nurse out of the home.

818. Which interventions are most appropriate for caring for a client in alcohol withdrawal? Select all that apply.
   □ 1. Monitor vital signs.
   □ 2. Provide a safe environment.
3. Address hallucinations therapeutically.
4. Provide stimulation in the environment.
5. Provide reality orientation as appropriate.

819. The nurse determines that the wife of an alcoholic client is benefiting from attending an Al-Anon group if the nurse hears the wife make which statement?
   1. “I no longer feel that I deserve the beatings my husband inflicts on me.”
   2. “My attendance at the meetings has helped me see that I provoke my husband’s violence.”
   3. “I enjoy attending the meetings because they get me out of the house and away from my husband.”
   4. “I can tolerate my husband’s destructive behaviors now that I know they are common among alcoholics.”

820. A hospitalized client with a history of alcohol misuse tells the nurse, “I am leaving now. I have to go. I don’t want any more treatment. I have things that I have to do right away.” The client has not been discharged and is scheduled for an important diagnostic test to be performed in 1 hour. After the nurse discusses the client’s concerns with the client, the client dresses and begins to walk out of the hospital room. What action should the nurse take?
   1. Call the nursing supervisor.
   2. Call security to block all exit areas.
   3. Restrain the client until the primary health care provider (PHCP) can be reached.
   4. Tell the client that the client cannot return to this hospital again if the client leaves now.

821. The nurse is preparing to perform an admission assessment on a client with a diagnosis of bulimia nervosa. Which assessment findings should the nurse expect to note? **Select all that apply.**
   1. Dental decay
   2. Moist, oily skin
   3. Loss of tooth enamel
   4. Electrolyte imbalances
   5. Body weight well below ideal range

822. The nurse is caring for a female client who was admitted to the mental health unit recently for anorexia nervosa. The nurse enters the client’s room and notes that the client is engaged in rigorous push-ups. Which nursing action is most appropriate?
   1. Interrupt the client and weigh her immediately.
   2. Interrupt the client and offer to take her for a walk.
   3. Allow the client to complete her exercise program.
   4. Tell the client that she is not allowed to exercise rigorously.
823. A client with a diagnosis of anorexia nervosa, who is in a state of starvation, is in a 2-bed room. A newly admitted client will be assigned to this client’s room. Which client would be the **best** choice as a roommate for the client with anorexia nervosa?

1. A client with pneumonia
2. A client undergoing diagnostic tests
3. A client who thrives on managing others
4. A client who could benefit from the client’s assistance at mealtime

824. The nurse is assessing a client who was admitted 24 hours ago for a fractured humerus. Which findings should alert the nurse to the potential for alcohol withdrawal delirium?

1. Hypotension, ataxia, hunger
2. Stupor, lethargy, muscular rigidity
3. Hypotension, coarse hand tremors, lethargy
4. Hypertension, changes in level of consciousness, hallucinations

825. The spouse of a client admitted to the mental health unit for alcohol withdrawal says to the nurse, “I should get out of this bad situation.” Which is the **most** helpful response by the nurse?

1. “Why don’t you tell your spouse about this?”
2. “What do you find difficult about this situation?”
3. “This is not the best time to make that decision.”
4. “I agree with you. You should get out of this situation.”

826. A client with anorexia nervosa is a member of a predischarge support group. The client verbalizes that she would like to buy some new clothes, but her finances are limited. Group members have brought some used clothes to the client to replace the client’s old clothes. The client believes that the new clothes are much too tight and has reduced her calorie intake to 800 calories daily. How should the nurse evaluate this behavior?

1. Normal behavior
2. Evidence of the client’s disturbed body image
3. Regression as the client is moving toward the community
4. Indicative of the client’s ambivalence about hospital discharge

## Answers

817. **Answer:** 2

**Rationale:** Whenever the nurse carries out an assessment for a client who is dependent on drugs, it is best for the nurse to attempt to elicit information by being nonjudgmental and direct. Option 1 is incorrect because it is judgmental and off-focus, and reflects the nurse’s bias. Option 3 is incorrect because it is judgmental, insensitive, and aggressive, which is nontherapeutic. Option 4 is incorrect because it indicates passivity on the nurse’s part and uses rationalization to avoid the therapeutic nursing intervention.

**Test-Taking Strategy:** Focus on the subject, assessment of a client dependent on drugs. Use of **therapeutic communication techniques** will assist in directing you to the correct option.
Rationale: When the client is experiencing withdrawal from alcohol, the priority for care is to prevent the client from harming self or others. The nurse would monitor the vital signs closely and report abnormal findings. The nurse would provide a low-stimulation environment to maintain the client in as calm a state as possible. The nurse would reorient the client to reality frequently and would address hallucinations therapeutically. Adequate nutritional and fluid intake need to be maintained.

Test-Taking Strategy: Note the strategic words, most appropriate. Thinking about the needs of the client in alcohol withdrawal and recalling the characteristics associated with alcohol withdrawal will assist in answering correctly. Also, use therapeutic communication techniques to assist in selecting the correct interventions.

Rationale: Al-Anon support groups are a protected, supportive opportunity for spouses and significant others to learn what to expect and to obtain excellent pointers about successful behavioral changes. The correct option is the healthiest response because it exemplifies an understanding that the alcoholic partner is responsible for his behavior and cannot be allowed to blame family members for loss of control. Option 2 is incorrect, because the nonalcoholic partner should not feel responsible when the spouse loses control. Option 3 indicates that the group is viewed as an escape, not as a place to work on issues. Option 4 indicates that the wife remains codependent.

Test-Taking Strategy: Focus on the subject, the therapeutic effect of attending an Al-Anon group. Noting the words benefiting from attending an Al-Anon group will direct you to the correct option.
Rationale: Most health care facilities have documents that the client is asked to sign relating to the client’s responsibilities when the client leaves against medical advice. The client should be asked to wait to speak to the PHCP before leaving and to sign the “against medical advice” document before leaving. If the client refuses to do so, the nurse cannot hold the client against the client’s will. Therefore, in this situation, the nurse should call the nursing supervisor. The nurse can be charged with false imprisonment if a client is made to believe wrongfully that she or he cannot leave the hospital. Restraining the client and calling security to block exits constitutes false imprisonment. All clients have a right to health care and cannot be told otherwise.

Test-Taking Strategy: Keeping the concept of false imprisonment in mind, eliminate options 2 and 3 because they are comparable or alike. Eliminate option 4, knowing that all clients have a right to health care. From the options presented, the best action is presented in the correct option.

Level of Cognitive Ability: Applying
Client Needs: Safe and Effective Care Environment
Integrated Process: Nursing Process—Implementation

Rationale: Clients with bulimia nervosa initially may not appear to be physically or emotionally ill. They are often at or slightly below ideal body weight. On further inspection, a client exhibits dental decay and loss of tooth enamel if the client has been inducing vomiting. Electrolyte imbalances are present. Dry, scaly skin (rather than moist, oily skin) is present.

Test-Taking Strategy: Focus on the subject, assessment findings in bulimia nervosa. It is necessary to recall that in anorexia nervosa the body weight is normally well below ideal body weight and that clients with bulimia nervosa are often at or slightly below ideal body weight. Also, remember that skin texture will be dry and scaly.

Level of Cognitive Ability: Analyzing
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Mental Health
Health Problem: Mental Health: Eating Disorders
Priority Concepts: Anxiety; Nutrition

822. Answer: 2

Rationale: Clients with anorexia nervosa frequently are preoccupied with rigorous exercise and push themselves beyond normal limits to work off caloric intake. The nurse must provide for appropriate exercise and place limits on rigorous activities. The correct option stops the harmful behavior yet provides the client with an activity to decrease anxiety that is not harmful. Weighing the client immediately reinforces the client’s preoccupation with weight. Allowing the client to complete the exercise program can be harmful to the client. Telling the client that she is not allowed to complete the exercise program will increase the client’s anxiety.

Test-Taking Strategy: Note the strategic words, most appropriate, and focus on the client’s diagnosis. Also, focus on the need for the nurse to maintain safety and to set firm limits with clients who have this disorder.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Mental Health
Health Problem: Mental Health: Eating Disorders
Priority Concepts: Anxiety; Safety

823. Answer: 2

Rationale: The client undergoing diagnostic tests is an acceptable roommate. The client with anorexia nervosa is most likely experiencing hematological complications, such as leukopenia. Having a roommate with pneumonia would place the client with anorexia nervosa at risk for infection. The client with anorexia nervosa should not be put in a situation in which the client can focus on the nutritional needs of others or be managed by others, because this may contribute to sublimation and suppression of personal hunger.

Test-Taking Strategy: Note the strategic word, best, and note the words in a state of starvation in the question. Recalling the characteristics of anorexia nervosa and that the client is immunocompromised as a result of starvation will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Safe and Effective Care Environment
Integrated Process: Nursing Process—Planning
Content Area: Mental Health
Health Problem: Mental Health: Eating Disorders
Priority Concepts: Care Coordination; Safety

824. Answer: 4

Rationale: Symptoms associated with alcohol withdrawal delirium typically
include anxiety, insomnia, anorexia, hypertension, disorientation, hallucinations, changes in level of consciousness, agitation, fever, and delusions.

**Test-Taking Strategy:** Focus on the **subject**, findings associated with withdrawal delirium. Review each option carefully to ensure that all symptoms in the option are correct. Eliminate options 1 and 3 first, knowing that hypertension rather than hypotension occurs. From the remaining options, recalling that the client who is stuporous is not likely to exhibit withdrawal delirium will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Addictions  
**Priority Concepts:** Addiction; Clinical Judgment  

825. **Answer:** 2

**Rationale:** The most helpful response is one that encourages the client to solve problems. Giving advice implies that the nurse knows what is best and can foster dependency. The nurse should not agree with the client, and the nurse should not request that the client provide explanations.

**Test-Taking Strategy:** Note the **strategic word**, most. Use therapeutic communication techniques. Eliminate option 1 because of the word *why*, which should be avoided in communication. Eliminate option 3, because this option places the client’s feelings on hold. Eliminate option 4, because the nurse is agreeing with the client. The correct option is the only one that addresses the client’s feelings.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Communication and Documentation  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Addictions  
**Priority Concepts:** Caregiving; Communication  

826. **Answer:** 2

**Rationale:** Disturbed body image is a concern with clients with anorexia nervosa. Although the client may struggle with ambivalence and show regressed behavior, the client’s coping pattern relates to the basic issue of disturbed body image. The nurse should address this need in the support group.

**Test-Taking Strategy:** Note the **subject**, signs of disturbed body image. Note the relationship between the information in the question and the correct option.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Mental Health
Health Problem: Mental Health: Eating Disorders
Priority Concepts: Anxiety; Coping
CHAPTER 67

Crisis Theory and Intervention

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Coping; Interpersonal Violence

I. Crisis Intervention
   A. Description
      1. Crisis is a temporary state of severe emotional disorganization caused by an event that presents a threat.
      2. Everyone experiences crises; the outcome depends on coping mechanisms and support systems available at the time of the crisis.
      3. The ability for decision making and problem solving is inadequate.
      4. Treatment is aimed at assisting the client and the family through the stressful situation.

   B. Phases of a crisis
      1. Phase 1: External precipitating event (could be situational, developmental, cultural, or societal)
      2. Phase 2
         a. Perception of the threat
         b. Increase in anxiety
         c. Client may cope or resolve the crisis.
      3. Phase 3
         a. Failure of coping
         b. Increasing disorganization
         c. Emergence of physical symptoms
         d. Relationship problems
      4. Phase 4
         a. Mobilization of internal and external resources
         b. Goal is to return the client to at least a precrisis level of functioning.

C. Types of crises (Box 67-1)

D. Crisis intervention
1. Treatment is immediate, supportive, and directly responsive to the immediate crisis.
2. The interprofessional health care team assists individuals in crisis to cope; interventions are goal directed.
3. Feelings of the client are acknowledged.
4. Intervention provides opportunities for expression and validation of feelings.
5. Connections are made between the meaning of the event and the crisis.
6. The client explores alternative coping mechanisms and tries out new behaviors.

II. Grief

A. Grief is a natural emotional response to loss that individuals must experience as they attempt to accept the loss.
B. Grief usually involves moving through a series of stages or tasks to help resolve the grief (Box 67-2).
C. Depending on the type of loss, feelings associated with grief include anger, frustration, loneliness, sadness, guilt, regret, and peace.
D. Healing can occur when the pain of the loss has lessened and the individual has adapted to the loss; if the grief is the result of the loss of a loved one, the individual continues to experience memories of the deceased.
E. Types of grief

1. Normal grief: Physical, emotional, cognitive, spiritual, or behavioral reactions can occur; the process of resolution can take months to years.
2. Anticipatory grief occurs before the loss of a loved one and is associated with an acute, chronic, or terminal illness.
3. Disenfranchised grief occurs when a loss of a loved one is experienced and cannot be acknowledged openly (societal norms do not define the loss as a loss within its traditional definition).
4. Dysfunctional grief occurs with prolonged emotional instability and a lack of progression to successful coping with the loss.
5. Grief in children is based on the developmental level of the child (Box 67-3).

III. Loss

A. Loss is the absence of something desired or previously thought to be available.
B. Actual loss can be identified by others and can arise in response to or in anticipation of a situation.
C. Perceived loss is experienced by one person and cannot be verified by others.
D. Anticipatory loss is experienced before the loss occurs.
E. Mourning
   1. Mourning is the outward and social expression of loss.
   2. Mourning may be dictated by cultural, spiritual, and religious beliefs.
F. Bereavement
   1. Bereavement includes the inner feelings and the outward reactions of the individual experiencing the loss.
   2. Bereavement includes grief and mourning.

IV. Nurse’s Role: Grief and Loss (Box 67-4)
A. Encourage the client to express feelings within a trusting, supportive, and nonjudgmental environment.
B. Allow ongoing opportunities for fully informed choices.
C. Facilitate the grief process; assess the individual’s grief, and assist the individual to feel the loss and complete the tasks of the grief process.
D. Grief affects individuals physically, psychologically, socially, and spiritually; an interprofessional team approach, including a bereavement specialist, facilitates the grief process.

The nurse’s role in the grief and loss process includes communicating with the client, family members, and significant other. The nurse must consider the individual’s culture, spirituality, religion, family structure, life experiences, coping skills, and support systems.

V. Suicidal Behavior
A. Description
   1. Suicidal clients characteristically have feelings of worthlessness, guilt, and hopelessness that are so overwhelming that they feel unable to go on with life and feel unfit to live.
   2. The nurse caring for a depressed client always considers the possibility of suicide.
B. Individuals at risk
   1. Clients with a history of previous suicide attempts
   2. Family history of suicide attempts
   3. Adolescents
   4. Older adults
   5. Disabled or terminally ill clients
   6. Clients with personality disorders
   7. Clients with organic brain syndrome or dementia
   8. Depressed or psychotic clients (see Chapter 65 for
information on depression)
9. Substance abusers
10. Those who have been consistently bullied or rejected by peers or society
11. History of child maltreatment
12. Past psychiatric hospitalizations

C. Cues (Box 67-5)
D. Assessment (Box 67-6)

E. Interventions

1. Assess for suicidal intent or ideation and initiate suicide precautions.
2. The client’s statements, behaviors, and mood are documented every 15 minutes.
3. Remove harmful objects.
4. Do not leave the client alone.
5. Provide a nonjudgmental, caring attitude.
6. Per agency procedure and policy, develop a no-suicide contract that is written, dated, and signed and indicates alternative behavior at times when suicidal thoughts occur and that they will notify the nurse when having suicidal thoughts.
7. Encourage the client to talk about feelings and to identify positive aspects about self.
8. Encourage active participation in own care.
9. Keep the client active by assigning achievable tasks.
10. Check that visitors do not leave harmful objects in the client’s room.
11. Identify support systems.
12. Do not allow the client to leave the unit unless accompanied by a staff member.
13. Continue to assess the client’s suicide potential.

VI. Abusive Behaviors
A. Anger

1. Anger is a feeling of annoyance that may be displaced onto an object or person.
2. Anger is used to avoid anxiety and gives a feeling of power in situations in which the person feels out of control.

B. Aggression can be harmful and destructive when not controlled.

C. Violence is physical force that is threatening to the safety of self and others.
D. Assessment
1. History of violence or self-harm
2. Poor impulse control and low tolerance of frustration
3. Defiant and argumentative
4. Raising of voice
5. Making verbal threats
6. Pacing and agitation
7. Muscle rigidity
8. Flushed face
9. Glaring at others

E. Interventions
1. Ensure a safe and low stimuli environment.
2. Use a calm approach and communicate with a calm, clear tone of voice (be assertive, not aggressive, and avoid verbal struggles).
3. Maintain a large personal space and use a nonaggressive posture (e.g., arms and hands at the side rather than folded across the chest or placed on the hips).
4. Listen actively and acknowledge the client’s anger.
5. Determine what the client considers to be her or his need.
6. Provide the client with clear options that deal with the client’s behavior, set limits on behavior, and make the client aware of the consequences of anger and violence.
7. Discuss the use of restraints (security devices) or seclusion if the client is unable to control angry behavior that may lead to violence.
8. Assist the client with problem solving and decision making regarding the options.

F. Restraints (security devices) and seclusion
1. Description
   a. Physical restraints: Any physical or environmental means of controlling an individual’s behavior or actions that inhibits free movement
   b. Seclusion: A type of restraint in which a client is confined in a room specially designed for protection and close supervision from which they cannot freely exit.
   c. Chemical restraints: Medications given for a specific purpose of inhibiting a specific behavior or movement and
that have an impact on the client’s ability to relate to the environment

2. Use of restraints and seclusion
   a. Restraints and seclusion should never be used as punishment or for the convenience of the health care staff.
   b. Restraints and seclusion are used when behavior is physically harmful to the client or others and when alternative or less restrictive measures are insufficient in protecting the client or others from harm.
   c. Restraints and seclusion are used when the health care team anticipates that a controlled environment would be helpful and requests restraints or seclusion.
   d. The nurse must document the behavior leading to the use of restraints or seclusion.
   e. In most settings, a primary health care provider’s prescription is required prior to the use of restraints.
   f. In an emergency, a qualified nurse may place a client in restraints or seclusion and obtain a written or verbal prescription as soon as possible thereafter.
   g. Per state guidelines, within 1 hour of the initiation of restraints or seclusion, the psychiatrist must make a face-to-face assessment and evaluation of the client and must continuously reevaluate the need for continued restraints or seclusion.
   h. While in restraints or seclusion, the client must be protected from all sources of harm.
   i. The client in restraints or seclusion needs constant one-to-one supervision; physical, safety, and comfort needs must be assessed every 15 to 30 minutes, and these observations are also documented.
(e.g., food, fluids, bathroom needs, range-of-motion exercise, and ambulation).

j. The nurse must always follow agency procedures and policies regarding the use of restraints and must also be familiar with their use for the older client and juveniles.

**VII. Bullying**

A. Bullying is the abuse of power by an individual toward another through repeated aggressive acts.

B. It most often occurs in children and in high school or college environments but can also occur in the workplace or other environments.

C. The bully feels power from sources such as physical strength, maturity, or a higher status within a peer group; from knowing the victim’s weaknesses; or from support of others.

D. Bullying can occur in the form of physical harm, relational aggression, isolation and exclusion, and verbal harm such as slander, rumors, or threats; it is both intentionally cruel and unprovoked.

E. Cyberbullying is also a form of bullying and occurs in the form of Internet messages on social media networks, text messages, e-mails, photos being posted, and rumors.

F. The bullied person repeatedly experiences negative actions from the bully(s).

G. These bullying acts can lead to depression, low self-esteem, humiliation, isolation, and social withdrawal in the victim; they could result in self-harm such as cutting, suicide, and murder.

H. The nurse’s responsibility is to observe for signs of bullying and to educate teachers, school administrators, and parents about bullying behaviors and signs that bullying may be occurring.

**VIII. Family Violence**

A. Description (Fig. 67-1)

1. Violence begins with threats or verbal or physical minor assaults (tension building), and the victim attempts to comply with the requests of the abuser.

2. The abuser loses control and becomes destructive and
harmful (acute battering), whereas the victim attempts to protect herself or himself.

3. After the battering, the abuser becomes loving and attempts to make peace (calmness and diffusion of tension); undoing behavior is characteristic in which the abuser gives gifts and positive attention to the victim to undo the negative behavior.

4. The abuser justifies that violence is normal and the victim is responsible for the abuse.

5. Outsiders are usually unaware of what is happening in the family.

6. Family members are isolated socially and lack autonomy and trust among each other; caring and intimacy in the family are absent.

7. Family members expect other members of the family to meet their needs, but none is able to do so.

8. The abuser threatens to abandon the family.

B. Types of violence (Box 67-7)

C. The vulnerable person (victim)

1. The vulnerable person is the one in the family unit against whom violence is perpetrated.

2. The most vulnerable individuals are children and older adults.

3. The perpetrator of violence and the person targeted by the violence can be male or female.

4. Battering is a crime.

D. Characteristics of abusers

1. Impaired self-esteem

2. Strong dependency needs

3. Narcissistic and suspicious

4. History of abuse during childhood

5. Perceive victims as their property and believe that they are entitled to abuse them

E. Characteristics of victims

1. Some may have a dependent personality disorder

2. Feel trapped, dependent, helpless, and powerless

3. May become depressed as they are trapped in the abusers’ power and control cycle (see Fig. 67-1)

4. As victims’ self-esteem becomes diminished with chronic abuse, they may blame themselves for the violence and be unable to see a way out of the situation.

F. Interventions

1. Report suspected or actual cases of child abuse or abuse of an older adult to appropriate authorities

2329
2. Referral to appropriate sexual assault domestic violence (SADV) team or other appropriate agency team
3. Assess for evidence of physical injuries.
4. Ensure privacy and confidentiality during the assessment, and provide a nonjudgmental and empathetic approach to foster trust; reassure the victim that she or he has not done anything wrong. Box 67-8 lists sample assessment questions.
5. Assist the victim to develop self-protective and other problem-solving abilities.
6. Even if the victim is not ready to leave the situation, encourage the victim to develop a specific safety plan (a fast escape if the violence returns) and provide information on where to obtain help (hotlines, safe houses, and shelters); an abused person is usually reluctant to call the police.
7. Assess suicidal potential of the victim.
8. Assess the potential for homicide.
9. Assess for the use of drugs and alcohol.
10. Determine family coping patterns and support systems.
11. Provide support and assistance in coping with contacting the legal system.
12. Assist in resolving family dysfunction with prescribed therapies.
13. Encourage individual therapy for the victim that promotes coping with the trauma and prevents further psychological conflict.
14. Encourage individual therapy for the abuser that focuses on preventing violent behavior and repairing relationships.
15. Encourage psychotherapy, counseling, group therapy, and support groups to assist family members to develop coping strategies.
16. Assist the family to identify an access to community and personal resources.
17. Maintain accurate and thorough medical health records.

IX. Child Abduction
   A. Description
      1. Child abduction is the kidnapping of a child (or infant) by an older person.
      2. Occurrences
         a. A stranger may kidnap a child for criminal or mischievous purposes.
         b. A stranger may kidnap a child (or
infant) to bring up him or her as that person’s own child.
c. A parent removes or retains a child from the other parent’s care (often in the course of or after divorce proceedings).

3. Because of the increased independence that occurs in the preschool-age child, parents are less able to provide the constant protection they once did when the child reaches this age; interventions that ensure protection (including teaching the child) are necessary.

4. Questions that help reveal the potential for abuse include: “Who do you play with most often? Is there anyone you do not like playing with? Are there games you don’t like playing?”

B. Interventions

1. Instruct the parents to teach a child basic guidelines about personal safety that include the following:
   a. Do not go anywhere alone.
   b. Always tell an adult where you are going and when you will return.
   c. Say no if you feel uncomfortable with a situation.
   d. If any adult offers you anything without asking your parent first, step away, say no, and tell someone.
   e. If any adult asks for your help without asking your parent first, step away, say no, and tell someone.
   f. If any adult asks you to keep a secret, say no and step away, say no, and tell someone.
   g. Do not help anyone look for a lost dog or cat and do not accept candy or gifts from a stranger.
   h. If lost in a store, do not wander around looking for the parent; go at once to a clerk or guard.

2. Children need to learn their full name, address, parents’ names and phone numbers.

3. Watch for post-traumatic stress disorder in any child who has experienced an abduction.

X. Child Abuse

A. Description
1. Abuse is the nonaccidental physical injury or the nonaccidental act of omission of care by a parent or person responsible for a child; abuse comprises neglect and physical, sexual, and emotional maltreatment.

2. Neglect can be in the form of physical or emotional neglect and involves the deprivation of basic needs, supervision, medical care, or education and failure to meet a child’s needs for attention and affection.

3. Sexual abuse can involve incest, molestation, exhibitionism, pornography, prostitution, or pedophilia; findings associated with sexual abuse may not be easily apparent in a child.

4. Shaken baby syndrome is caused by the violent shaking of an infant and results in intracranial (usually subdural hemorrhage) trauma; this can lead to cerebral edema and death.

B. Assessment (Box 67-9)

C. Interventions

1. Support the child during a thorough physical assessment.

2. Assess injuries.

3. If shaken baby syndrome is suspected, monitor the infant for a decrease in level of consciousness, which can indicate increased intracranial pressure (ICP).

4. Report a case of suspected abuse; nurses are legally required to report all cases of suspected child abuse to the appropriate local or state agency.

5. Place the child in an environment that is safe, preventing further injury.

6. Document information related to the suspected abuse in an objective manner.

7. Assess parents’ strengths and weaknesses, normal coping mechanisms, and presence or absence of support systems.

8. Assist the family in identifying stressors, support systems, and resources.

9. Refer the family to appropriate support groups.

——-

XI. Latchkey Children

A. Description

Nurses are legally required to report all cases of suspected child abuse or elder abuse to the appropriate local or state agency; state laws and procedures may vary and are always followed.
1. Children who do not have adult supervision before or after school hours; they are left to care for themselves during these times.
2. Occurs when children are members of a single-parent family or when both parents work and need to leave the home before children are brought to school or arrive home after the children.
3. This situation induces a stress-provoking environment for the children and places the children at risk for an unsafe situation, injury, and delinquent behavior.

B. Interventions
1. Identify the latchkey child.
2. Encourage the parent to teach the child about self-care and self-help skills.
3. Assist the parent to identify possible alternatives to leaving the child alone.
4. Inform the parent about available community resources such as after-school programs for children.

XII. Abuse of the Older Adult

A. Description
1. Abuse of an older adult involves physical, emotional, or sexual abuse; neglect; and economic exploitation.
2. Older adults at most risk include individuals who are dependent because of illness, immobility, or altered mental status.
3. Factors that contribute to abuse and neglect include long-standing family violence, caregiver stress, and the older adult’s increasing dependence on others.
4. Victims may attempt to dismiss injuries as accidental, and abusers may prevent victims from receiving proper medical care to avoid discovery.
5. Victims often are isolated socially by their abusers.

B. Assessment
1. Physical abuse
   a. Sprains, dislocations, or fractures
   b. Abrasions, bruises, or lacerations
   c. Pressure sores
   d. Puncture wounds
   e. Burns
   f. Skin tears
2. Sexual abuse
   a. Torn or stained underclothing
   b. Discomfort or bleeding in the genital
area
c. Difficulty in walking or sitting
d. Unexplained genital infections or disease

3. Emotional abuse
   a. Confusion
   b. Fearfulness and agitation
   c. Changes in appetite and weight
   d. Withdrawal and loss of interest in self and social activities

4. Neglect
   a. Disheveled appearance
   b. Inadequate or inappropriate dress
   c. Dehydration and malnutrition
   d. Lack of physical needs, such as glasses, hearing aids, and dentures

5. Signs of medication overdose
6. Economic exploitation
   a. Inability to pay bills and fearful when discussing finances
   b. Confusion, inaccuracy, or no knowledge of finances

C. Interventions

1. Assess for physical injuries and treat physical injuries.
2. Ask if any injury is a result of someone harming them.
3. Report cases of suspected abuse to appropriate authorities (follow state and agency guidelines).
4. Separate the older adult from the abusive environment, if possible, and contact adult protective services for assistance in placement while the abuse is being investigated.
5. Explore alternative living arrangements that are least restrictive and disruptive to the victim.
6. The older adult who has been abused may need assistance for financial or legal matters.
7. Provide referrals to emergency community resources.
8. When working with caregivers, assess the need for respite care or counseling to deal with caregiver stress (see Priority Nursing Actions).

Priority Nursing Actions

Physical Abuse of an Older Client
1. Assess and treat the wounds.
2. Ensure that the victim is removed from the threatening environment.
XIII. Rape and Sexual Assault

A. Description

1. Rape is engaging another person in a sexual act or sexual intercourse through the use of force or coercion and without the consent of the sexual partner.
2. The victim is not required by law to report the rape or assault.
3. Often, the victim is blamed by others and receives no support from significant others.
4. Acquaintance rape involves someone known to the victim.
5. Statutory rape is the act of sexual intercourse with a person younger than the age of legal consent, even if the minor consents.
6. Same-sex rape
   a. Females: Involves sexual touching, oral sex, or penetration with a finger or some other object
   b. Males: Same as for females; often experience stigma when seeking help
   c. See https://www.cdc.gov/violenceprevention/index.html for more information.
7. Marital rape
   a. The belief that marriage bestows rights to sex whenever wanted and without consent of the partner contributes to the occurrence of marital rape.
   b. Victims of marital rape describe being forced to perform acts they did not wish to perform and being physically abused during sex.

B. Assessment

1. Female client
   a. Obtain the date of the last menstrual period.
   b. Determine the form of birth control used and the last act of intercourse before rape.
c. Determine the duration of intercourse, orifices violated, and whether penile penetration occurred.
d. Determine whether a condom was used by the perpetrator.

C. Shame, embarrassment, and humiliation
D. Anger and revenge
E. Afraid to tell others because of fear of not being believed
F. Males may be sexually abused as children and as adults and are the usual targeted victim of pedophiles; males may have more difficulty with disclosing their abuse.

G. Rape trauma syndrome
   1. Sleep disturbances, nightmares
   2. Loss of appetite
   3. Fears, anxiety, phobias, suspicion
   4. Decrease in activities and motivation
   5. Disruptions in relationships with partner, family, friends
   6. Self-blame, guilt, shame
   7. Lowered self-esteem, feelings of worthlessness
   8. Somatic complaints

H. Interventions
   1. Perform the assessment in a quiet, private area.
   2. Referral to SADV nurse as appropriate
   3. Stay with the victim and provide client safety.
   4. Assess the client for physical injuries. Treat as appropriate.
   5. Assess the victim’s stress level before performing treatments and procedures.
   6. Victim should not shower, bathe, douche (female), or change clothing until an examination is performed.
   7. Obtain written consent for the examination, photographs, laboratory tests, release of information, and laboratory samples.
   8. Assist with the female pelvic examination and obtain specimens to detect semen (the pelvic examination may trigger a flashback of the attack); a shower and fresh clothing should be made available to the client after the examination.
   10. Treat physical injuries and provide client safety.
   11. Administer prescribed medications.
   12. Document all events in the care of the victim.
   13. Reinforce to the victim that surviving the assault is most important; if the victim survived the rape, she or
he did exactly what was necessary to stay alive.
14. Refer the victim to crisis intervention and support groups.

Box 67-1

**Types of Crises**

**Maturational**

- Relates to developmental stages and associated role changes; examples include marriage, birth of a child, and retirement

**Situational**

- Arises from an external source, is often unanticipated, and is associated with a life event that upsets an individual’s or group’s psychological equilibrium; examples include loss of a job or a change in job, change in financial status, death of a loved one, divorce, abortion, addition of new family members, pregnancy, and severe physical or mental illness

**Adventitious**

- Relates to a crisis of disaster, is not a part of everyday life; it is unplanned and accidental. Adventitious crises may result from a natural disaster (e.g., floods, fires, tornadoes, earthquakes), a national disaster (e.g., war, riots, airplane crashes), or a crime of violence (e.g., rape, assault, murder in the workplace or school, bombings, or spousal or child abuse).

Box 67-2

**The Grief Response**

**Stage 1: Shock and Disbelief**

- Individual may have feelings of numbness, difficulties with decision making, emotional outbursts, denial, and isolation.

**Stage 2: Experiencing the Loss**

- If the grief response is the result of a loss of a loved one, the individual may feel
angry at the loved one who died or may feel guilt about the death.
• Bargaining or depression or both also may occur in this stage.

Stage 3: Reintegration

• Individual begins to reorganize her or his life and accepts the reality of the loss.

Box 67-3
Grief in Children

Birth to 1 Year

• Infant has no concept of death.
• Infant reacts to the loss of mother or caregiver.

1 to 2 Years

• Toddler may see death as reversible.
• Toddler may scream, withdraw, or become disinterested in the environment.
• Grief response occurs only to the death of the significant person in the toddler’s life.

2 to 5 Years

• Child may see death as reversible.
• Regressive or aggressive behavior may occur.
• Child has a sense of loss and is concerned about who will provide care.

5 to 9 Years

• Child has difficulty concentrating.
• Child begins to see death as permanent.
• Child may feel responsible for the occurrence.

Preadolescent Through Adolescent

• Adolescent may regress.
• Adolescent sees death as permanent.
• Adolescent experiences a strong emotional reaction.
**Box 67-4**

**Communication During Grief and Loss**

- Determine how much the client and family want to know about the situation.
- Determine whether there is a spokesperson for the family.
- Be aware of cultural, spiritual, and religious beliefs and how they may affect the communication process; consider personal space issues, eye contact, and touch.
- Obtain an interpreter, if necessary.
- Allow opportunity for informed choices.
- Assist with the decision-making process if asked; use problem solving to assist in decision making, and avoid interjecting personal views or opinions.
- Establish trust with the client and encourage expression of feelings, concerns, and fears within a trusting, supportive, and nonjudgmental environment.
- Be honest, and let the client and family know that you will not abandon them.
- Ask the client and family about their expectations and needs.
- Be a sensitive listener; sit in silence if necessary and appropriate.
- Extend touch and hold the client’s or family member’s hand if appropriate.
- Encourage reminiscing.
- If you do not know what to do in a particular situation, seek assistance.
- If you do not know what to say to a client or family who is talking about death or another loss, listen attentively and use therapeutic communication techniques, such as open-ended questions or reflection.
- Acknowledge your own feelings; let the client and family know that the topic of conversation is a difficult one and that you do not know what to say.
- Realize that it is acceptable to cry with the client and family during the grief process.

**Box 67-5**

**Suicidal Cues**

- Giving away personal, special, and prized possessions
- Canceling social engagements
- Making out or changing a will
- Taking out or changing insurance policies
- Positive or negative changes in behavior
- Poor appetite
- Sleeping difficulties
- Feelings of hopelessness
- Difficulty in concentrating
- Loss of interest in activities
- Client statements indicating an intent to attempt suicide
- Sudden calmness or improvement in a depressed client
- Client inquiries about poisons, guns, or other lethal items or objects
- Sudden deterioration in school/work performance

**Box 67-6**

**Suicidal Client: Assessment**

**Plan**

- Does the client have a plan?
- Does the client have the means to carry out the plan?
- Has the client decided when she or he is going to carry out the plan?

**Client History of Attempts**

- What suicide attempts occurred in the past and what harm occurred?
- Was the client accidentally rescued?
- Have the past attempts and methods been the same, or have methods increased in lethality?

**Psychosocial Factors**

- Is the client alone or alienated from others?
- Is hostility or depression present?
- Is the client experiencing hallucinations? Type of hallucination (audio/command, visual)?
- Is substance abuse present?
- Has the client had any recent losses or physical illness?
- Has the client had any environmental or lifestyle changes?
**Box 67-7**

**Types of Violence**

- **Physical Violence:** Infliction of physical pain or bodily harm
- **Sexual Violence:** Any form of sexual contact without consent
- **Emotional Violence:** Infliction of mental anguish
- **Physical Neglect:** Failure to provide health care to prevent or treat physical or emotional illnesses
- **Developmental Neglect:** Failure to provide physical and cognitive stimulation needed to prevent developmental deficits
- **Educational Neglect:** Depriving a child of education
- **Economic Exploitation:** Illegal or improper exploitation of money, funds, or other resources for one’s personal gain
Box 67-8

Assessment Questions for Violence and Abuse

▪ “Has anyone ever touched you in a way that made you uncomfortable?”
▪ “Are these injuries a result of someone harming you?”
▪ “Is anyone hurting you now?”
▪ “How do you and your partner deal with anger (or disagreement)?”
▪ “Has your partner ever hit you?”
▪ “Have you ever been threatened by _____?”
▪ “Does your partner prevent you from seeing family or friends?”
▪ “Does your partner ever use the children to manipulate you?”
▪ “Did (or does) anyone in your family deal with anger by hitting?”

Box 67-9

Child Neglect and Abuse: Assessment Findings

Neglect

▪ Inadequate weight gain
▪ Poor hygiene
▪ Consistent hunger
▪ Inconsistent school attendance
▪ Constant fatigue
▪ Reports of lack of child supervision
▪ Delinquency

Physical Abuse

▪ Unexplained bruises, burns, or fractures
▪ Bald spots on the scalp
▪ Apprehensive child
▪ Extreme aggressiveness (typically boys) or withdrawal (typically girls)
▪ Fear of parents
▪ Lack of crying (older infant, toddler, or young preschool child) when approached by a stranger
▪ Spiral fractures without history of trauma from a sports injury
▪ Poor performance in school

Emotional Abuse
Speech disorders
• Habit disorders such as sucking, biting, and rocking
• Psychoneurotic reactions
• Learning disorders
• Suicide attempts

Sexual Abuse
• Difficulty walking or sitting
• Torn, stained, or bloody underclothing
• Pain, swelling, or itching of genitals
• Deformities, bruises, bleeding, or lacerations in genital or anal area
• Unwillingness to change clothes or unwillingness to participate in gym activities
• Poor peer relations
• Poor performance in school

Shaken Baby Syndrome
• External signs of trauma are usually absent
• Ophthalmoscopic examination reveals retinal hemorrhages
• Full bulging fontanels and head circumference greater than expected

Practice Questions

827. The nurse observes that a client with a potential for violence is agitated, pacing up and down the hallway, and making aggressive and belligerent gestures at other clients. Which statement would be most appropriate to make to this client?

1. “You need to stop that behavior now.”
2. “You will need to be placed in seclusion.”
3. “You seem restless; tell me what is happening.”
4. “You will need to be restrained if you do not change your behavior.”

828. The nurse is reviewing the assessment data of a client admitted to the mental health unit. The nurse notes that the admission nurse documented the client is experiencing anxiety as a result of a situational crisis. The nurse plans care for the client, determining that this type of crisis could be caused by which event?

1. Witnessing a murder
2. The death of a loved one
3. A fire that destroyed the client’s home
4. A recent rape episode experienced by the client

829. The nurse is conducting an initial assessment of a client in crisis. When assessing the client’s perception of the precipitating event that led to the
crisis, which is the **most appropriate** question?
1. “With whom do you live?”
2. “Who is available to help you?”
3. “What leads you to seek help now?”
4. “What do you usually do to feel better?”

830. The nurse is creating a plan of care for a client in a crisis state. When developing the plan, the nurse should consider which factor?
1. A crisis state indicates that the client has a mental illness.
2. A crisis state indicates that the client has an emotional illness.
3. Presenting symptoms in a crisis situation are similar for all clients experiencing a crisis.
4. A client’s response to a crisis is individualized and what constitutes a crisis for one client may not constitute a crisis for another client.

831. The nurse in the emergency department is caring for a young female victim of sexual assault. The client’s physical assessment is complete, and physical evidence has been collected. The nurse notes that the client is withdrawn, distracted, tremulous, and bewildered at times. How should the nurse interpret these behaviors?
1. Signs of depression
2. Reactions to a devastating event
3. Evidence that the client is a high suicide risk
4. Indicative of the need for hospital admission

832. A depressed client on an inpatient unit says to the nurse, “My family would be better off without me.” Which is the nurse’s **best** response?
1. “Have you talked to your family about this?”
2. “Everyone feels this way when they are depressed.”
3. “You will feel better once your medication begins to work.”
4. “You sound very upset. Are you thinking of hurting yourself?”

833. The nurse has been closely observing a client who has been displaying aggressive behaviors. The nurse observes that the behavior displayed by the client is escalating. Which nursing intervention is **most** helpful to this client at this time? **Select all that apply.**

1. Initiate confinement measures.
2. Acknowledge the client’s behavior.
3. Assist the client to an area that is quiet.
4. Maintain a safe distance from the client.
5. Allow the client to take control of the situation.

834. Which behavior observed by the nurse indicates a suspicion that a depressed adolescent client may be suicidal?
1. The adolescent gives away a DVD and a cherished autographed picture of a performer.
2. The adolescent runs out of the therapy group, swearing at the group leader, and to her room.
3. The adolescent becomes angry while speaking on the telephone.
and slams down the receiver.

4. The adolescent gets angry with her roommate when the roommate borrows the client’s clothes without asking.

835. The police arrive at the emergency department with a client who has lacerated both wrists. Which is the initial nursing action?
   1. Administer an antianxiety agent.
   2. Assess and treat the wound sites.
   3. Secure and record a detailed history.
   4. Encourage and assist the client to ventilate feelings.

836. A moderately depressed client who was hospitalized 2 days ago suddenly begins smiling and reporting that the crisis is over. The client says to the nurse, “I’m finally cured.” Based on the client’s behavior and statement, which intervention should the nurse include in the plan?
   1. Suggesting a reduction of medication
   2. Allowing increased “in-room” activities
   3. Increasing the level of suicide precautions
   4. Allowing the client off-unit privileges as needed

837. The nurse is planning care for a client being admitted to the nursing unit who attempted suicide. Which priority nursing intervention should the nurse include in the plan of care?
   1. One-to-one suicide precautions
   2. Suicide precautions with 30-minute checks
   3. Checking the whereabouts of the client every 15 minutes
   4. Asking the client to report suicidal thoughts immediately

838. The emergency department nurse is caring for an adult client who is a victim of family violence. Which priority information should be included in the discharge instructions?
   1. Information regarding shelters
   2. Instructions regarding calling the police
   3. Instructions regarding self-defense classes
   4. Explaining the importance of leaving the violent situation

839. A female victim of a sexual assault is being seen in the crisis center. The client states that she still feels “as though the rape just happened yesterday,” even though it has been a few months since the incident. Which is the most appropriate nursing response?
   1. “You need to try to be realistic. The rape did not just occur.”
   2. “It will take some time to get over these feelings about your rape.”
   3. “Tell me more about the incident that causes you to feel like the rape just occurred.”
   4. “What do you think that you can do to alleviate some of your fears about being raped again?”

840. A client is admitted to the mental health unit after an attempted suicide by hanging. The nurse can best ensure client safety by which action?
   1. Requesting that a peer remain with the client at all times.
   2. Removing the client’s clothing and placing the client in a hospital gown.
   3. Assigning to the client a staff member who will remain with the client at all times.
4. Admitting the client to a seclusion room where all potentially dangerous articles are removed.

841. A client is admitted with a recent history of severe anxiety following a home invasion and robbery. During the initial assessment interview, which statement by the client should indicate to the nurse the possible diagnosis of post-traumatic stress disorder? Select all that apply.

- 1. “I’m afraid of spiders.”
- 2. “I keep reliving the robbery.”
- 3. “I see his face everywhere I go.”
- 4. “I don’t want anything to eat now.”
- 5. “I might have died over a few dollars in my pocket.”
- 6. “I have to wash my hands over and over again many times.”

**Answers**

827. **Answer:** 3

**Rationale:** The most appropriate statement is to ask the client what is causing the agitation. This will assist the client to become aware of the behavior and may assist the nurse in planning appropriate interventions for the client. Option 1 is demanding behavior that could cause increased agitation in the client. Options 2 and 4 are threats to the client and are inappropriate.

**Test-Taking Strategy:** Note the strategic words, most appropriate. Eliminate option 1 because of the demand that it places on the client. Eliminate options 2 and 4 because they indicate threats to the client.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Communication and Documentation

**Content Area:** Mental Health

**Health Problem:** Mental Health: Abusive Behaviors

**Priority Concepts:** Anxiety; Communication

**Reference:** Varcarolis (2017), pp. 140, 143.

828. **Answer:** 2

**Rationale:** A situational crisis arises from external rather than internal sources. External situations that could precipitate a crisis include loss or change of a job, the death of a loved one, abortion, change in financial status, divorce, addition of new family members, pregnancy, and severe illness. Options 1, 3, and 4 identify adventitious crises. An adventitious crisis refers to a crisis of disaster, is not a part of everyday life, and is unplanned and accidental. Adventitious crises may result from a natural disaster (e.g., floods, fires, tornadoes, earthquakes), a national disaster (e.g., war, riots, airplane crashes), or a crime of violence (e.g., rape, assault, murder in the
workplace or school, bombings, or spousal or child abuse).

Test-Taking Strategy: Note the subject, situational crisis. Recall that this type of crisis arises from an external source, is often unanticipated, and is associated with a life event that upsets an individual’s or group’s psychological equilibrium. This will direct you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Planning
Content Area: Mental Health
Health Problem: Mental Health: Anxiety Disorder
Priority Concepts: Anxiety; Coping

829. Answer: 3

Rationale: The nurse’s initial task when assessing a client in crisis is to assess the individual or family and the problem. The more clearly the problem can be defined, the better the chance a solution can be found. The correct option would assist in determining data related to the precipitating event that led to the crisis. Options 1 and 2 assess situational supports. Option 4 assesses personal coping skills.

Test-Taking Strategy: Note the strategic words, most appropriate. Also note the subject, assessment techniques for the client in crisis, and note the words precipitating event and led to the crisis. Eliminate options 1 and 2, because these data would determine support systems. Eliminate option 4, because this question would be asked when determining coping skills.

Level of Cognitive Ability: Analyzing
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Mental Health
Health Problem: Mental Health: Crisis
Priority Concepts: Anxiety; Coping

830. Answer: 4

Rationale: Although each crisis response can be described in similar terms as far as presenting symptoms are concerned, what constitutes a crisis for one client may not constitute a crisis for another client, because each is a unique individual. Being in the crisis state does not mean that the client has a mental or emotional illness.

Test-Taking Strategy: Eliminate option 3 because of the closed-ended word “all.” Next, eliminate options 1 and 2, because a crisis does not indicate “illness.”

Level of Cognitive Ability: Creating
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Planning
Content Area: Mental Health
Health Problem: Mental Health: Crisis
Priority Concepts: Caregiving; Coping

831. **Answer:** 2

**Rationale:** During the acute phase of the rape crisis, the client can display a wide range of emotional and somatic responses. The symptoms noted indicate an expected reaction. Options 1, 3, and 4 are incorrect interpretations.

**Test-Taking Strategy:** Note the subject, client response to a crisis. Use knowledge regarding client responses to devastating events and focus on the symptoms noted in the question to direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Mental Health

**Health Problem:** Mental Health: Crisis

**Priority Concepts:** Caregiving; Coping

832. **Answer:** 4

**Rationale:** Clients who are depressed may be at risk for suicide. It is critical for the nurse to assess suicidal ideation and plan. The nurse should ask the client directly whether a plan for self-harm exists. Options 1, 2, and 3 do not deal directly with the client’s feelings.

**Test-Taking Strategy:** Note the strategic word, best. Recalling therapeutic communication techniques will assist in directing you to the correct option. Option 4 is the only option that deals directly with the client’s feelings. In addition, clients at risk for suicide need to be assessed directly regarding the potential for self-harm.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Communication and Documentation

**Content Area:** Mental Health

**Health Problem:** Mental Health: Suicide

**Priority Concepts:** Clinical Judgment; Safety

833. **Answer:** 2, 3, 4

**Rationale:** During the escalation period, the client’s behavior is moving toward loss of control. Nursing actions include taking control, maintaining a safe distance, acknowledging behavior, moving the client to a quiet area, and medicating the client if appropriate. To initiate confinement measures during this period is inappropriate. Initiation of confinement measures, if needed, is most appropriate during the crisis period.

**Test-Taking Strategy:** Focus on the strategic word, most, and focus on the subject, the most helpful nursing interventions. Also note the words aggressive behaviors and escalating. Recalling that, during the escalation period, the client’s behavior is
moving toward loss of control and that the least restrictive measures should be used
will direct you to the correct options.

Level of Cognitive Ability: Analyzing
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Mental Health
Health Problem: Mental Health: Violence
Priority Concepts: Clinical Judgment; Safety

834. Answer: 1

Rationale: A depressed suicidal client often gives away that which is of value as a
way of saying goodbye and wanting to be remembered. Options 2, 3, and 4 deal with
anger and acting-out behaviors that are often typical of an adolescent.
Test-Taking Strategy: Eliminate options 2, 3, and 4 because they are comparable
or alike. The correct option is different and is an action that could indicate that the
client may be “saying goodbye.”

Level of Cognitive Ability: Analyzing
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Mental Health
Health Problem: Mental Health: Suicide
Priority Concepts: Mood and Affect; Safety

835. Answer: 2

Rationale: The initial nursing action is to assess and treat the self-inflicted injuries.
Injuries from lacerated wrists can lead to a life-threatening situation. Other
interventions, such as options 1, 3, and 4, may follow after the client has been treated
medically.
Test-Taking Strategy: Note the strategic word, initial. Use Maslow’s Hierarchy of
Needs theory to prioritize. Physiological needs come first. The correct option
addresses the physiological need.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Complex Care: Emergency Situations: Management
Health Problem: Mental Health—Suicide
Priority Concepts: Caregiving; Safety

836. Answer: 3

Rationale: A client who is moderately depressed and has only been in the hospital
2 days is unlikely to have such a dramatic cure. When a depression suddenly lifts, it
is likely that the client may have made the decision to harm herself or himself. Suicide precautions are necessary to keep the client safe. The remaining options are therefore incorrect interpretations.

**Test-Taking Strategy:** Focus on the **subject**, suicide precautions. Options 1 and 4 support the client’s notion that a cure has occurred. Option 2 allows the client to increase self-isolation and would present a threat to the client’s safety. Knowing that safety is of the utmost importance will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Planning

**Content Area:** Mental Health

**Health Problem:** Mental Health: Mood Disorders

**Priority Concepts:** Caregiving; Safety

837. **Answer:** 1

**Rationale:** One-to-one suicide precautions are required for a client who has attempted suicide. Options 2 and 3 may be appropriate, but not at the present time, considering the situation. Option 4 also may be an appropriate nursing intervention, but the priority is identified in the correct option. The best intervention is constant supervision so that the nurse may intervene as needed if the client attempts to harm herself or himself.

**Test-Taking Strategy:** Focus on the **strategic word**, priority, noting the words **attempted suicide**. The correct option is the only one that provides a safe environment.

**Level of Cognitive Ability:** Applying

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Complex Care: Emergency Situations: Management

**Health Problem:** Mental Health: Suicide

**Priority Concepts:** Caregiving; Safety

838. **Answer:** 1

**Rationale:** Tertiary prevention of family violence includes assisting the victim after the abuse has already occurred. The nurse should provide the client with information regarding where to obtain help, including a specific plan for removing the self from the abuser and information regarding escape, hotlines, and the location of shelters. An abused person is usually reluctant to call the police. Teaching the victim to fight back is not the appropriate action for the victim when dealing with a violent person. Explaining the importance of leaving the violent situation is important, but a specific plan is necessary.

**Test-Taking Strategy:** Note the **strategic word**, priority. Focus on the **subject** of the question, which relates to providing the client with a safe environment. The correct option provides a specific plan for safety.

**Level of Cognitive Ability:** Applying
**Client Needs:** Safe and Effective Care Environment  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Violence  
**Priority Concepts:** Interpersonal Violence; Safety  

839. **Answer:** 3

**Rationale:** The correct option allows the client to express her ideas and feelings more fully and portrays a nonhurried, nonjudgmental, supportive attitude on the part of the nurse. Clients need to be reassured that their feelings are normal and that they may express their concerns freely in a safe, caring environment. Option 1 immediately blocks communication. Option 2 places the client’s feelings on hold. Option 4 places the problem solving totally on the client.

**Test-Taking Strategy:** Note the strategic words, *most appropriate*. Also, focus on the subject, that the client feels that the rape just happened yesterday. Use *therapeutic communication techniques*. The correct option is the only one that addresses the client’s feelings. Always address the client’s feelings first.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Caring  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Therapeutic Communication  
**Priority Concepts:** Communication; Coping  

840. **Answer:** 3

**Rationale:** Hanging is a serious suicide attempt. The plan of care must reflect action that ensures the client’s safety. Constant observation status (one-to-one) with a staff member is the best choice. Placing the client in a hospital gown and requesting that a peer remain with the client would not ensure a safe environment. Seclusion should not be the initial intervention, and the least restrictive measure should be used.

**Test-Taking Strategy:** Note the strategic word, *best*. Focus on the subject, care of the client at risk for suicide. Eliminate option 4, because seclusion should not be the initial intervention. Eliminate option 1 next, because safeguarding a client is not the peer’s responsibility. Eliminate option 2, because removing one’s clothing would not maximize all possible safety strategies.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Safe and Effective Care Environment  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Suicide  
**Priority Concepts:** Caregiving; Safety  
841. **Answer:** 2, 3, 5

**Rationale:** Reliving an event, experiencing emotional numbness (facing possible death), and having flashbacks of the event (seeing the same face everywhere) are all common occurrences with post-traumatic stress disorder. The statement “I’m afraid of spiders” relates more to having a phobia. The statement “I have to wash my hands over and over again many times” describes ritual compulsive behaviors to decrease anxiety for someone with obsessive-compulsive disorder. Stating “I don’t want anything to eat now” is vague and could relate to numerous conditions.

**Test-Taking Strategy:** Focus on the subject, post-traumatic stress disorder. There is no indication about a fear of spiders being part of the problem. There is no information in the question to support that the client has ritual behaviors. The client stating that they do not want anything to eat at the time is not relevant to this client’s situation. Responses 2, 3, and 5 all indicate that the client is experiencing post-traumatic stress disorder from a recent home invasion and robbery event.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Mental Health

**Health Problem:** Mental Health: Post-Traumatic Stress Disorder

**Priority Concepts:** Anxiety; Coping

I. Selective Serotonin Reuptake Inhibitors (SSRIs) (Box 68-1)
   A. Description
      1. Inhibit serotonin uptake and elicit an antidepressant response
      2. Effective for depression with anxiety features as well as depression with psychomotor agitation
      3. Relatively low side-effect profile compared with older antidepressants (tricyclics)
      4. Do not create anticholinergic effects, dry mouth, blurred vision, or urinary retention
      5. May interact with other medications (e.g., digoxin, warfarin).
      6. The potential for medication interactions is greatest when administered with second serotonin-enhancing agent, such as a monoamine oxidase inhibitor (MAOI). A complete medication assessment must be obtained and evaluated; inquire about the use of herbal therapies, especially St. John’s wort.
   B. Side and adverse effects
      1. Dry mouth
      2. Blood pressure changes
      3. Insomnia, somnolence (sleepy, drowsy), apathy
      4. Nervousness
      5. Weight loss or gain
      6. Decreased libido
      7. Apathy
      8. Tremors
      9. Seizure activity
      10. Potential toxic effects (too high dose or interaction with other drugs)
          a. Abdominal pain, diarrhea
          b. Sweating, fever
          c. Tachycardia, elevated blood pressure
          d. Altered mental state (delirium)
e. Myoclonus (muscle spasms), increased motor activity

C. Interventions

1. Monitor vital signs, because SSRIs can potentially lower or elevate blood pressure.
2. May cause sexual dysfunction or lack of sex drive. Inform health care provider if this occurs.
3. Initiate safety precautions and contact the PHCP if dizziness occurs.
4. Instruct the client to avoid alcohol.
5. Administer with a snack or meal to reduce the risk of dizziness and lightheadedness.
6. Monitor the suicidal client, especially during improved mood and increased energy levels.
7. Instruct the client that taking ibuprofen with SSRIs increases the risk of an upper GI bleed.
8. For the client on long-term therapy, monitor liver and renal function test results; altered values may occur, requiring dosage adjustments.
9. Monitor white blood cell and neutrophil counts; the medication may be discontinued if levels decrease below normal.
10. Instruct to change positions slowly if experiencing a hypotensive effect.
11. Educate the client to not discontinue medication abruptly. Abrupt cessation can lead to serotonin withdrawal characterized by gastrointestinal distress, movement disorders, insomnia, and sensory disturbances.
12. Be aware of the potential for serotonin syndrome, characterized by hyperactivity or restlessness, tachycardia, fever, elevated blood pressure, altered mental status (delirium), mood swings, seizures, muscle rigidity, and abdominal pain; this risk is greatly increased when SSRIs are given with MAOIs. This medication combination needs to be avoided.
13. Instruct that over-the-counter (OTC) cold medicines may increase the likelihood of serotonin syndrome.
14. In pregnancy, consultation with an obstetrician is recommended regarding taking these medications.
15. Monitor the medication response in children, adolescents, and older adults closely, because the response may be different than in an adult client.
16. Encourage psychotherapy.
17. Serotonin-norepinephrine reuptake inhibitors (SNRI) are similar to SSRIs, but they also work by blocking the effects of norepinephrine in addition to serotonin.
Considerations are similar to that of SSRIs.

II. Tricyclic Antidepressants (Box 68-2)

A. Description

1. Block the reuptake of norepinephrine and serotonin at the presynaptic junction; used to treat depression
2. Also affect other neurotransmitters, leading to a number of side effects
3. May reduce seizure threshold
4. May reduce effectiveness of antihypertensive agents
5. Concurrent use with alcohol or antihistamines can cause CNS depression.
6. Concurrent use with MAOIs can cause hypertensive crisis.

7. Cardiac toxicity can occur, and all clients should receive an electrocardiogram (ECG) before treatment and periodically thereafter.
8. Overdose is life-threatening, necessitating immediate treatment (see Priority Nursing Actions).

Priority Nursing Actions

Tricyclic Antidepressant Overdose

1. Check airway and maintain a patent airway.
2. Administer oxygen and ventilation (as required).
3. Check vital signs and cardiac monitoring.
4. Obtain an electrocardiogram.
5. Prepare for gastric lavage with activated charcoal if within 2 hours of ingestion.
6. Administer intravenous fluids as prescribed.
7. Prepare to administer medications as prescribed to reverse the effects of the tricyclic antidepressant.
8. Document the event, actions taken, and the client’s response.

Reference

9. The tricyclic antidepressant clomipramine may be used to treat obsessive-compulsive disorder.

B. Side and adverse effects

1. Anticholinergic effects: Dry mouth, difficulty voiding, dilated pupils and blurred vision, decreased gastrointestinal motility, constipation
2. Urinary retention
3. Cardiovascular disturbances such as tachycardia or dysrhythmias; orthostatic hypotension
4. Sedation
5. Seizures (with bupropion)
6. Weight gain or weight loss
7. Anxiety, restlessness, irritability, confusion
8. Decreased or increased libido with ejaculatory and erection disturbances
9. Symptoms of tricyclic antidepressant (TCA) toxicity
   a. Tardive dyskinesia: involuntary movement of the face and jaw
   b. Akinesia: loss of voluntary muscle movement
   c. Akathisia: state of agitation, distress, and restlessness
   d. Pseudoparkinsonism

C. Interventions

1. Monitor the suicidal client, especially during improved mood and increased energy levels.
2. Instruct the client to change positions slowly to avoid a hypotensive effect.
4. Assess for urinary retention.
5. For the client on long-term therapy, monitor liver and renal function test results.
6. Administer with food or milk if gastrointestinal distress occurs.
7. Administer the entire daily oral dose preferably at bedtime because of the sedative effect. Do not split doses, such as taking half in the morning and half in the evening.
8. Instruct the client to avoid alcohol and nonprescription medications to prevent adverse medication interactions.
9. Instruct the client to avoid driving and other activities requiring alertness until the response is known; sedation is expected in early therapy and may subside with time.
10. When the medication is discontinued by the primary health care provider (PHCP), it should be tapered gradually.
11. The potential for medication interactions with OTC cold medications exists.
12. Encourage oral hygiene and the use of hard candies and mouth rinses to relieve dry mouth.
13. Encourage psychotherapy.

Inform the client that antidepressant medication may take several weeks to produce the desired effect (client response may not
occur until 2 to 4 weeks after the first dose).

III. Monoamine Oxidase Inhibitors (MAOIs) (Box 68-3)

A. Description

1. Inhibit the enzyme monoamine oxidase, which is present in the brain, blood platelets, liver, spleen, and kidneys.
2. Monoamine oxidase metabolizes amines (dopamine, tyramine), norepinephrine, and serotonin, so the concentration of these amines increases with MAOIs.
3. Clients who have depression and have not responded to other antidepressant therapies, including electroconvulsive therapy, may be given MAOIs. These medications are not the first choice because of other available medications and the possible serious side and adverse effects that can occur.
4. Concurrent use with amphetamines, antidepressants, dopamine, epinephrine, levodopa/carbidopa, nasal decongestants, norepinephrine, tyramine-containing foods, or vasoconstrictors may cause hypertensive crisis.
5. Concurrent use with opioid analgesics may cause hypertension or hypotension, coma, or seizures.

B. Side and adverse effects

1. Orthostatic hypotension
2. Changes in cardiac rate and rhythm
3. Restlessness
4. Insomnia
5. Dizziness and vertigo
6. Weakness, lethargy
7. Gastrointestinal upset or constipation
8. Urinary hesitancy
9. Dry mouth
10. Weight gain
11. Peripheral edema
12. Anticholinergic effects
13. CNS stimulation (anxiety, agitation, mania)
14. Sexual dysfunction

C. Hypertensive crisis

1. Hypertension
2. Occipital headache radiating frontally
3. Neck stiffness and soreness
4. Nausea and vomiting
5. Sweating
6. Fever and chills
7. Clammy skin
8. Dilated pupils
9. Palpitations, tachycardia, or bradycardia
10. Constricting chest pain
11. Antidote for hypertensive crisis: Phentolamine by intravenous injection

D. Interventions

1. Monitor blood pressure frequently for hypertension.
3. If palpitations or frequent headaches occur, withhold the medication and notify the PHCP.
4. Administer with food if gastrointestinal distress occurs.
5. Instruct the client that the medication effect may be noted during the first week of therapy, but maximum benefit may take 3 weeks.
6. Instruct the client to report headache, neck stiffness, or neck soreness immediately.
7. Instruct the client to change positions slowly to prevent orthostatic hypotension.
8. Instruct the client to avoid caffeine or OTC preparations such as weight-reducing pills or medications for hay fever and colds.
9. Monitor compliance with medication administration.
10. Instruct the client that she or he may take a missed dose within 3 hours of the scheduled time; otherwise, the client should skip the missed dose and take the next dose at the scheduled time.
11. Instruct the client to carry a MedicAlert card indicating that an MAOI medication is being taken.
12. Avoid administering the medication in the evening, because insomnia may result.
13. When the medication is discontinued by the PHCP, it should be discontinued gradually.
14. Instruct the client to avoid foods that require bacteria or molds for their preparation or preservation and foods that contain tyramine (Fig. 68-1; Box 68-4).

Teach the client about foods that contain tyramine. Consuming tyramine-containing foods when taking an MAOI can cause hypertensive crisis.

IV. Mood Stabilizers (Box 68-5)

A. Description: Affect cellular transport mechanism and enhance serotonin or γ-aminobutyric acid (GABA) function, or both, which are associated with mood
B. Lithium

1. Concurrent use with diuretics, fluoxetine, or nonsteroidal antiinflammatory drugs increases
2. Lithium reabsorption by the kidneys or inhibits lithium excretion, either of which increases the risk of lithium toxicity.

2. Acetazolamide, theophylline, phenothiazines, or sodium bicarbonate may increase renal excretion of lithium, reducing its effectiveness.

3. The therapeutic dose is only slightly less than the amount producing toxicity.

4. The therapeutic medication serum level of lithium is 0.6 to 1.2 mEq/L (0.6 to 1.2 mmol/L); the actual dose at which the therapeutic effect is achieved and the levels at which toxicity occurs are highly variable among individual clients.

5. The causes of an increase in the lithium level include decreased sodium intake; fluid and electrolyte loss associated with excessive sweating, dehydration, diarrhea, or diuretic therapy; and illness or overdose.

6. Serum lithium levels should be checked frequently after initiation of therapy and then every 1 to 2 months or whenever any behavioral change suggests an altered serum level.

7. Blood samples to check serum lithium levels should be drawn in the morning, 12 hours after the last dose was taken.

8. Lithium is classified as pregnancy category D; it crosses the placental barrier freely and has been associated with fetal toxicity.

C. Side and adverse effects
   1. Polyuria
   2. Polydipsia
   3. Edema
   4. Dysrhythmia
   5. Anorexia, nausea
   6. Dry mouth, mild thirst
   7. Abdominal bloating
   8. Soft stools or diarrhea
   9. Fine hand tremors
   10. Inability to concentrate
   11. Muscle weakness
   12. Headache
   13. Hypothyroidism and goiter

D. Interventions
   1. Monitor the suicidal client, especially during improved mood and increased energy levels.
   2. Administer the medication with food to minimize

2359
3. Instruct the client to avoid excessive amounts of coffee, tea, or cola, which have a diuretic effect.
4. Do not administer diuretics while the client is taking lithium.
5. Instruct the client to avoid alcohol.
6. Instruct the client to avoid OTC medications.
7. Instruct the client that she or he may take a missed dose within 2 hours of the scheduled time; otherwise, the client should skip the missed dose and take the next dose at the scheduled time.
8. Instruct the client not to adjust the dosage or stop the medication without consulting the PHCP, because lithium should be tapered and not discontinued abruptly.
9. Instruct the client about the signs and symptoms of lithium toxicity.
10. Instruct the client to notify the PHCP if polyuria, prolonged vomiting, diarrhea, or fever occurs.
11. Instruct the client that the therapeutic response to the medication is noted in 1 to 3 weeks.
12. Monitor the ECG, renal function tests, and thyroid tests (ensure that these tests are performed before the start of therapy).

**Instruct the client taking lithium to maintain a fluid intake of 6 to 8 glasses of water a day and an adequate salt intake to prevent lithium toxicity.**

E. Lithium toxicity

1. Description
   a. Occurs when ingested lithium cannot be detoxified and excreted by the kidneys
   b. Symptoms of toxicity begin to appear when the serum lithium level is at 1.5 mEq/L (1.5 mmol/L).

2. Mild toxicity
   a. Serum lithium level of 1.5 mEq/L (1.5 mmol/L)
   b. Apathy
   c. Lethargy
   d. Diminished concentration
   e. Mild ataxia
   f. Coarse hand tremors
   g. Slight muscle weakness

3. Moderate toxicity
a. Serum lithium level of 1.5 to 2.0 mEq/L (1.5 to 2.0 mmol/L)
b. Nausea, vomiting
c. Severe diarrhea
d. Mild to moderate ataxia and incoordination
e. Slurred speech
f. Tinnitus
g. Blurred vision
h. Muscle twitching
i. Irregular tremor

4. Severe toxicity
   a. Serum lithium level greater than 2.0 mEq/L (2.0 mmol/L)
   b. Nystagmus
c. Muscle fasciculations
d. Deep tendon hyper-reflexia
e. Visual or tactile hallucinations
f. Oliguria or anuria
g. Impaired level of consciousness
h. Tonic-clonic seizures or coma, leading to death

5. Interventions for lithium toxicity
   a. Withhold lithium and notify the PHCP.
   b. Monitor vital signs and level of consciousness.
c. Monitor cardiac status.
d. Prepare to obtain samples to monitor lithium, electrolyte, blood urea nitrogen, and creatinine levels and perform a complete blood cell count.
e. Monitor for suicidal tendencies and institute suicide precautions.

V. Antianxiety or Anxiolytic Medications
   A. Description
   1. Antianxiety medications depress the CNS, increasing the effects of GABA, which produces relaxation and may depress the limbic system.
   2. Benzodiazepines have anxiety-reducing (anxiolytic), sedative-hypnotic, muscle-relaxing, and anticonvulsant actions (Box 68-6).
   3. Benzodiazepines are contraindicated in clients with acute narrow-angle glaucoma and should be used cautiously in children and older adults.
   4. Benzodiazepines interact with other CNS medications, producing an additive effect, and therefore should only be considered for short-term use.
5. Abrupt withdrawal of benzodiazepines can be potentially life-threatening, and withdrawal should occur only under medical supervision.

B. Side and adverse effects
1. Daytime sedation
2. Dizziness
3. Headaches
4. Blurred or double vision
5. Hypotension
6. Tremor
7. Amnesia
8. Slurred speech
9. Constipation or diarrhea
10. Lethargy
11. Behavioral change

C. Acute toxicity
1. Somnolence
2. Confusion
3. Diminished reflexes and coma
4. Flumazenil, a benzodiazepine antagonist administered intravenously, reverses benzodiazepine intoxication in 5 minutes.
5. A client being treated for an overdose of a benzodiazepine may experience agitation, restlessness, discomfort, and anxiety.

D. Interventions
1. Monitor for motor responses such as agitation, trembling, and tension.
2. Monitor for autonomic responses such as cold, clammy hands and sweating.
3. Monitor for paradoxical CNS excitement during early therapy, particularly in older adults and debilitated clients.
4. Monitor for visual disturbances, because the medications can worsen glaucoma.
5. Monitor liver and renal function test results and complete blood cell counts.
6. Reduce the medication dose as prescribed for the older adult client and for the client with impaired liver function.
7. Initiate safety precautions, because the older adult client is at risk for falling when taking the medication for sleep or anxiety.
8. Assist with ambulation if drowsiness or lightheadedness occurs.
9. Instruct the client that drowsiness usually disappears during continued therapy.

10. Instruct the client to avoid tasks that require alertness until the response to the medication is established.

11. Instruct the client to avoid alcohol.

12. Instruct the client not to take other medications without consulting the PHCP.

13. Instruct the client not to stop the medication abruptly (can result in seizure activity).

E. Withdrawal

1. To lessen withdrawal symptoms, the dosage of a benzodiazepine should be tapered gradually over 2 to 6 weeks.

2. Abrupt or too rapid withdrawal results in the following:
   a. Restlessness
   b. Irritability
   c. Insomnia
   d. Hand tremors
   e. Abdominal or muscle cramps
   f. Sweating
   g. Vomiting
   h. Seizures

VI. Barbiturates and Sedative-Hypnotics (Box 68-7)

A. Description

1. Depress the reticular activating system by promoting the inhibitory synaptic action of the neurotransmitter GABA

2. Used for short-term treatment of insomnia or for sedation to relieve anxiety, tension, and apprehension

B. Side and adverse effects

1. Dizziness and drowsiness
2. Confusion
3. Irritability
4. Allergic reactions
5. Agranulocytosis
6. Thrombocytopenic purpura
7. Megaloblastic anemia

C. Overdose

1. Tachycardia
2. Hypotension
3. Cold and clammy skin
4. Dilated pupils
5. Weak and rapid pulse
6. Signs of shock
7. Depressed respirations
8. Absent reflexes
9. Coma and death may result from respiratory and cardiovascular collapse.

D. Withdrawal
1. Severe withdrawal symptoms begin within 24 hours after the medication is discontinued in an individual with severe medication dependence.
2. Gradual withdrawal is used to detoxify a dependent client.
3. Anxiety
4. Behavioral changes
5. Insomnia
6. Nightmares
7. Daytime agitation
8. Tremors
9. Delirium
10. Seizures

E. Interventions
1. Administer lower doses as prescribed for the older client.
2. Medications should be used with caution in the client who has suicidal tendencies or has a history of drug addiction.
3. Maintain safety by supervising ambulation and using side rails at night as appropriate.
4. Instruct the client to take the medication as directed.
5. Instruct the client to avoid driving or operating hazardous equipment if drowsiness, dizziness, or unsteadiness occurs.
6. Instruct the client to avoid alcohol, because this allows more medication to enter the brain, causing feelings of depression and drowsiness, dizziness, slow and difficult breathing, confusion, and coma.
7. For clients with insomnia, instruct the client to take the medication 30 minutes before bedtime; avoid taking with a large amount of food to help absorption.
8. Instruct the client that a hangover effect may occur in the morning.
9. Instruct the client not to discontinue the medication abruptly.
10. Instruct clients taking chloral hydrate to take the medication with food and a full glass of water, fruit juice, or ginger ale to prevent gastric irritation.

VII. Antipsychotic Medications (Box 68-8)
A. Description
1. Improve the thought processes and behavior of the client with psychotic symptoms, especially clients with schizophrenia.
2. Affect dopamine receptors in the brain, reducing psychotic symptoms
3. Typical antipsychotics are more effective for positive symptoms of schizophrenia, such as hallucinations, aggression, and delusions; these medications also block the chemoreceptor trigger zone and vomiting center in the brain, producing an antiemetic effect.
4. Atypical antipsychotics are more effective for the negative symptoms of schizophrenia, such as avolition, apathy, and alogia.
5. The effects of antipsychotic medications are potentiated when given with other medications acting on the CNS.

B. Side and adverse effects (Box 68-9)

C. Extrapiramidal syndrome: Can include parkinsonism, dystonia, akathisia, or tardive dyskinesia (see Box 68-9)

D. Interventions

1. Monitor vital signs.
2. Monitor for symptoms of neuroleptic malignant syndrome (can occur with antipsychotic medications); refer to Section VIII.
4. Monitor serum glucose level.
5. Administer the medication with food or milk to decrease gastric irritation.
6. For oral use, the liquid form might be preferred, because some clients hide tablets in their mouths to avoid taking them.
7. The absorption rate is faster with the liquid form of oral medication.
8. Avoid skin contact with the liquid concentrate to prevent contact dermatitis.
9. Protect the liquid concentrate from light.
10. Dilute the liquid concentrate with fruit juice.
11. Injectable form of risperdal consta is administered every 2 weeks for clients who have difficulty with medication adherence.
12. Inform the client that a full therapeutic effect of the medication may not be evident for 3 to 6 weeks after initiation of therapy; however, an observable therapeutic response may be apparent after 7 to 10 days.
13. Inform the client that some medications may cause a harmless change in urine color to pinkish to red-brown.
14. Instruct the client to use sunscreen, hats, and protective clothing when outdoors.
15. Instruct the client to avoid alcohol or other CNS depressants, because these substances will allow more of the medication to enter the brain, causing feelings of depression and drowsiness, dizziness, slow and difficult breathing, confusion, and coma.

16. Instruct the client to change positions slowly to avoid orthostatic hypotension.

17. Instruct the client to report signs of agranulocytosis, including sore throat, fever, and malaise.

18. Instruct the client to report signs of liver dysfunction, including jaundice, malaise, fever, and right upper abdominal pain.

19. When discontinuing antipsychotics, the medication dosage should be reduced gradually to avoid sudden recurrence of psychotic symptoms.

Monitor for extrapyramidal side and adverse effects in the client taking an antipsychotic medication.

VIII. Neuroleptic Malignant Syndrome

A. Description

1. A potentially fatal syndrome that may occur at any time during therapy with neuroleptic (antipsychotic) medications (typically with first generation antipsychotics).

2. Although rare, neuroleptic malignant syndrome more commonly occurs at the initiation of therapy, after the client has changed from one medication to another, after a dosage increase, or when a combination of medications is used.

B. Assessment

1. Dyspnea or tachypnea
2. Tachycardia or irregular pulse rate
3. Autonomic dysfunction
   a. Hyperpyrexia
   b. Hypertension
   c. Tachycardia
   d. Tachypnea
   e. Diaphoresis
   f. Drooling
4. High or low blood pressure
5. Excessive weakness or fatigue
6. Altered level of consciousness
7. Seizures
8. Severe extrapyramidal side and adverse effects
9. Skeletal muscle rigidity
10. Difficulty swallowing
11. Oculogyric crisis
12. Elevated white blood cell count, liver function results, and creatine phosphokinase level

C. Interventions

1. Notify the PHCP.
2. Monitor vital signs.
3. Initiate safety and seizure precautions.
4. Prepare to discontinue the medication.
5. Monitor level of consciousness.
6. Administer antipyretics as prescribed.
7. Use a cooling blanket to lower the body temperature.
8. Monitor electrolyte levels and administer fluids intravenously as prescribed.
9. Monitor for complications such as deep vein thrombosis (DVT) and rhabdomyolysis.

IX. Medications to Treat Attention-Deficit/Hyperactivity Disorder (Box 68-10)

A. Children with attention-deficit/hyperactivity disorder may require medication to reduce hyperactive behavior and lengthen attention span.
B. Medications that are most effective in controlling this disorder are CNS stimulants.
C. CNS stimulants, which increase agitation and activity in adults, have a calming effect on children with attention-deficit/hyperactivity disorder and increase alertness and sensitivity to stimuli.
D. Side and adverse effects
   1. Tachycardia
   2. Anorexia and weight loss
   3. Elevated blood pressure
   4. Dizziness
   5. Agitation
E. Interventions
   1. Monitor for CNS side and adverse effects.
   2. Obtain a baseline ECG.
   3. Monitor the blood pressure.
   4. Instruct the child and parents that OTC medications need to be avoided.
   5. Instruct the child and parents that the last dose of the day should be taken at least 6 hours before bedtime (14 hours for extended-release forms) to prevent insomnia.
   7. Reinforce that several weeks of therapy may be necessary before the therapeutic effect is noted.
   8. Instruct the client and parents that a medication-free period may be prescribed to demonstrate the
continued need for the medication, and temporarily remove side effects of the medication, which commonly include sleep delay, appetite suppression, and tolerance to treatment.

X. Medications to Treat Alzheimer’s Disease (Box 68-11)

A. Acetylcholinesterase inhibitors may be used in clients with Alzheimer’s disease to improve cognitive functions in the early stages.

B. Donepezil

1. An inhibitor of acetylcholinesterase used to treat mild to moderate dementia of Alzheimer’s disease
2. Side and adverse effects include nausea and diarrhea.
3. Donepezil can slow the heart rate through its vagotonic effect.

C. Galantamine

1. An inhibitor of cholinesterase used to treat mild to moderate dementia of Alzheimer’s disease
2. Side and adverse effects include nausea, vomiting, diarrhea, anorexia, and weight loss.
3. Galantamine can cause bronchoconstriction; it should be used with caution in clients with asthma and chronic obstructive pulmonary disease.

D. Memantine

1. \(N\)-Methyl-\(d\)-aspartate (NMDA) receptor antagonist indicated for treatment of moderate to severe dementia of Alzheimer’s disease
2. Side and adverse effects include dizziness, headache, confusion, and constipation.
3. Memantine should not be used in combination with other NMDA receptor antagonists such as amantadine or ketamine; such combinations produce undesirable additive effects.
4. Sodium bicarbonate and other medications that alkalinize the urine can decrease renal excretion of memantine; accumulation to toxic levels can result.
5. Clearance is reduced with renal impairment; therefore, use with caution.

E. Rivastigmine

1. Cholinesterase inhibitor used to treat mild to moderate dementia of Alzheimer’s disease
2. Side and adverse effects include nausea, vomiting, diarrhea, anorexia, and weight loss.
3. Should be taken with food to reduce gastrointestinal side effects.
4. Rivastigmine should be used with caution in clients with peptic ulcer disease, bradycardia, sick sinus syndrome, urinary obstruction, and lung disease
because it enhances cholinergic transmission, intensifying symptoms of these disorders.

Box 68-1

Reuptake Inhibitors

Selective Serotonin Reuptake Inhibitors

- Citalopram
- Escitalopram
- Fluoxetine
- Fluvoxamine
- Paroxetine
- Sertraline
- Vilazodone

Serotonin-Norepinephrine Reuptake Inhibitors

- Desvenlafaxine
- Duloxetine
- Levomilnacipran
- Venlafaxine

Atypical Antidepressants

- Bupropion
- Mirtazapine
- Nefazodone
- Trazodone
- Vortioxetine

Box 68-2

Tricyclic Antidepressants

- Amitriptyline
- Amoxapine
- Clomipramine
- Desipramine
- Doxepin
Box 68-3

**Monoamine Oxidase Inhibitors (MAOIs)**

- Isocarboxazid
- Phenelzine (not approved for use in Canada)
- Selegiline
- Tranylcypromine

---

**FIG. 68-1** Interaction between dietary tyramine and monoamine oxidase inhibitors (MAOIs). A, In the absence of MAOIs, much of the ingested tyramine is inactivated by...
MAO in the intestinal wall (not shown in the figure). Any dietary tyramine that is not metabolized in the intestinal wall is transported directly to the liver, where it undergoes immediate inactivation by hepatic MAO. No tyramine reaches the general circulation. B, Three events occur in the presence of MAOIs: (1) inhibition of neuronal MAO increases levels of norepinephrine (NE) in sympathetic nerve terminals; (2) inhibition of intestinal and hepatic MAO allows dietary tyramine to pass through the intestinal wall and liver and enter the systemic circulation intact; (3) on reaching peripheral sympathetic nerve terminals, tyramine promotes the release of accumulated NE stores, causing massive vasoconstriction and excessive stimulation of the heart. R, Receptor for NE.

**Box 68-4**

**Foods That Contain Tyramine**

- Avocados
- Bananas
- Beef or chicken liver
- Brewer’s yeast
- Broad beans
- Caffeine, such as in coffee, tea, or chocolate
- Cheese, especially aged, except cottage cheese
- Eggplant
- Figs
- Meat extracts and tenderizers
- Overripe fruit
- Papaya
- Pickled herring
- Raisins
- Red wine, beer, sherry
- Sauerkraut
- Sausage, bologna, pepperoni, salami
- Sour cream
- Soy sauce
- Yogurt

*Note:* These foods need to be avoided by the client taking an MAOI. Even a small amount of tyramine can increase the blood pressure and the force and/or rate of heart contractions.

**Box 68-5**

**Mood Stabilizers**

**Lithium Preparation**
• Lithium carbonate

**Other Mood Stabilizers**

• Aripiprazole
• Brexpiprazole
• Carbamazepine
• Clozapine
• Gabapentin
• Lamotrigine
• Olanzapine
• Olanzapine/fluoxetine
• Oxcarbazepine
• Paliperidone
• Quetiapine
• Risperidone
• Valproate
• Ziprasidone

**Box 68-6**

**Benzodiazepines**

• Alprazolam
• Chlordiazepoxide
• Clonazepam
• Clorazepate
• Diazepam
• Lorazepam
• Midazolam
• Temazepam
• Triazolam

**Nonbenzodiazepine Anxiolytic**

• Buspirone

**Box 68-7**

**Barbiturates and Sedative-Hypnotics**
Barbiturates

- Phenobarbital
- Secobarbital

Sedative-Hypnotics

- Chloral hydrate
- Eszopiclone
- Meprobamate
- Ramelteon
- Suvorexant
- Tasimelteon
- Zaleplon
- Zolpidem

Box 68-8

Antipsychotic Medications

Typical Antipsychotics

- Chlorpromazine
- Fluphenazine decanoate
- Haloperidol
- Perphenazine
- Trifluoperazine

Atypical Antipsychotics

- Aripiprazole
- Asenapine
- Brexpiprazole
- Cariprazine
- Clozapine
- Lurasidone
- Olanzapine
- Paliperidone
- Pimavanserin
- Quetiapine
- Risperidone
- Ziprasidone
Side and Adverse Effects of Antipsychotic Medications

Anticholinergic Effects

- Dry mouth
- Increased heart rate
- Urinary retention
- Constipation
- Hypotension

Extrapyramidal Effects

- Parkinsonism
- Tremors
- Mask-like facies
- Rigidity
- Shuffling gait
- Dysphagia
- Drooling

Dystonias

- Abnormal or involuntary eye movements, including oculogyric crisis
- Facial grimacing
- Twisting of the torso or other muscle groups

Akathisia

- Restlessness
- Constant moving about

Tardive Dyskinesia

- Protrusion of the tongue
- Chewing motion
- Involuntary movements of the body and extremities

Other Side and Adverse Effects
Drowsiness
Blood dyscrasias
Pruritus
Photosensitivity
Elevated blood glucose level
Increased weight
Impaired body temperature regulation
Gynecomastia
Lactation

**Box 68-10**

**Medications to Treat Attention-Deficit/Hyperactivity Disorder**

- Amphetamine
- Atomoxetine
- Dexamphetamine
- Dextroamphetamine
- Dextroamphetamine and amphetamine
- Guanfacine
- Lisdexamfetamine
- Methylphenidate

**Box 68-11**

**Medications to Treat Alzheimer’s Disease**

- Donepezil
- Galantamine
- Memantine
- Rivastigmine

**Practice Questions**

842. A client’s medication sheet contains a prescription for sertraline. To ensure safe administration of the medication, how should the nurse administer the dose?

1. On an empty stomach
2. At the same time each evening
3. Evenly spaced around the clock
4. As needed when the client complains of depression

843. A client with schizophrenia has been started on medication therapy with clozapine. The nurse should assess the results of which laboratory study to monitor for adverse effects from this medication?
   1. Platelet count
   2. Blood glucose level
   3. Liver function studies
   4. White blood cell count

844. A client is scheduled for discharge and will be taking phenobarbital for an extended period. The nurse would place **highest priority** on teaching the client which point that directly relates to client safety?
   1. Take the medication only with meals.
   2. Take the medication at the same time each day.
   3. Use a dose container to help prevent missed doses.
   4. Avoid drinking alcohol while taking this medication.

845. The nurse is describing the medication side and adverse effects to a client who is taking amitriptyline. Which information should the nurse incorporate in the discussion?
   1. Consume a low-fiber diet.
   2. Increase fluids and bulk in the diet.
   3. Rest if the heart begins to beat rapidly.
   4. Walk if you have difficulty urinating because this is a normal side effect.

846. The nurse is administering risperidone to a client with schizophrenia who is scheduled to be discharged. Before discharge, which instruction should the nurse provide to the client?
   1. Get adequate sunlight.
   2. Continue driving as usual.
   3. Avoid foods rich in potassium.
   4. Get up slowly when changing positions.

847. The nurse is teaching a client who is being started on imipramine about the medication. The nurse should inform the client to expect maximum desired effects at which time period following initiation of the medication?
   1. In 2 months
   2. In 2 to 3 weeks
   3. During the first week
   4. During the sixth week of administration

848. A hospitalized client is started on a monoamine oxidase inhibitor (MAOI) for the treatment of depression. The nurse should instruct the client that which foods are acceptable to consume while taking this medication? **Select all that apply.**
   1. Figs
   2. Yogurt
   3. Crackers
   4. Aged cheese
5. Tossed salad  
6. Oatmeal raisin cookies

849. The nurse notes that a client with schizophrenia and receiving an antipsychotic medication is moving her mouth, protruding her tongue, and grimacing as she watches television. The nurse determines that the client is experiencing which medication complication?
1. Parkinsonism  
2. Tardive dyskinesia  
3. Hypertensive crisis  
4. Neuroleptic malignant syndrome

850. The nurse is performing a follow-up teaching session with a client discharged 1 month ago. The client is taking fluoxetine. Which information would be important for the nurse to obtain during this client visit regarding the side and adverse effects of the medication?
1. Cardiovascular symptoms  
2. Gastrointestinal dysfunctions  
3. Problems with mouth dryness  
4. Problems with excessive sweating

851. A client who has been taking buspirone for 1 month returns to the clinic for a follow-up assessment. The nurse determines that the medication is effective if the absence of which manifestation has occurred?
1. Paranoid thought process  
2. Rapid heartbeat or anxiety  
3. Alcohol withdrawal symptoms  
4. Thought broadcasting or delusions

852. A client taking lithium reports vomiting, abdominal pain, diarrhea, blurred vision, tinnitus, and tremors. The lithium level is 2.5 mEq/L (2.5 mmol/L). The nurse plans care based on which representation of this level?
1. Toxic  
2. Normal  
3. Slightly above normal  
4. Excessively below normal

853. A client gives the home health nurse a bottle of clomipramine. The nurse notes that the medication has not been taken by the client in 2 months. Which behavior observed in the client would validate noncompliance with this medication?
1. Complaints of insomnia  
2. Complaints of hunger and fatigue  
3. A pulse rate less than 60 beats per minute  
4. Frequent hand washing with hot, soapy water

854. A hospitalized client has begun taking bupropion as an antidepressant agent. The nurse determines that which is an adverse effect, indicating that the client is taking an excessive amount of medication?
1. Constipation  
2. Seizure activity  
3. Increased weight  
4. Dizziness when getting upright

2377
A client receiving tricyclic antidepressants arrives at the mental health clinic. Which observation would indicate that the client is following the medication plan correctly?

1. Client reports not going to work for the past week.
2. Client complains of not being able to “do anything” anymore.
3. Client arrives at the clinic neat and appropriate in appearance.
4. Client reports sleeping 12 hours per night and 3 to 4 hours during the day.

**Answers**

842. *Answer: 2*

*Rationale:* Sertraline is classified as an antidepressant. Sertraline generally is administered once every 24 hours. It may be administered in the morning or evening, but evening administration may be preferable because drowsiness is a side effect. The medication may be administered without food or with food if gastrointestinal distress occurs. Sertraline is not prescribed for use as needed.

*Test-Taking Strategy:* Focus on the *subject*, administration of sertraline. Recalling that this medication is an antidepressant administered daily will direct you to the correct option.

*Level of Cognitive Ability: Applying*

*Client Needs: Physiological Integrity*

*Integrated Process: Nursing Process—Implementation*

*Content Area: Pharmacology: Psychotherapeutics: Selective Serotonin Reuptake Inhibitors (SSRIs)*

*Health Problem: Mental Health: Mood Disorders*

*Priority Concepts: Mood and Affect; Safety*

843. *Answer: 4*

*Rationale:* A client taking clozapine may experience agranulocytosis, which is monitored by reviewing the results of the white blood cell count. Treatment is interrupted if the white blood cell count decreases to less than 3000 mm³ \( (3 \times 10^9/L) \). Agranulocytosis could be fatal if undetected and untreated. The other laboratory studies are not related specifically to the use of this medication.

*Test-Taking Strategy:* Focus on the *subject*, complications associated with clozapine. It is necessary to recall that this medication causes agranulocytosis; this will direct you to the correct option.

*Level of Cognitive Ability: Analyzing*

*Client Needs: Physiological Integrity*

*Integrated Process: Nursing Process—Assessment*

*Content Area: Pharmacology: Psychotherapeutic: Antipsychotics*

*Health Problem: Mental Health: Schizophrenia*

*Priority Concepts: Cellular Regulation; Psychosis*

844. **Answer:** 4

**Rationale:** Phenobarbital is an anticonvulsant and hypnotic agent. The client should avoid taking any other central nervous system depressants such as alcohol while taking this medication. The medication may be given without regard to meals. Taking the medication at the same time each day enhances compliance and maintains more stable blood levels of the medication. Using a dose container or “pillbox” may be helpful for some clients.

**Test-Taking Strategy:** Focus on the subject, client safety, and note the strategic words, highest priority. Eliminate option 1 because of the closed-ended word only. Although options 2 and 3 are correct teaching points, these are not the highest priority from the options provided. Remember that alcohol should not be consumed when a hypnotic is taken because of its adverse effects.

**Level of Cognitive Ability:** Applying

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Psychotherapeutics: Barbiturate and sedative-hypnotics

**Health Problem:** N/A

**Priority Concepts:** Client Education; Safety

**Reference:** Hodgson, Kizior (2018), pp. 932-933

845. **Answer:** 2

**Rationale:** Amitriptyline causes constipation, and the client is instructed to increase fluid intake and bulk (high fiber) in the diet. If the heart begins to beat fast, the primary health care provider (PHCP) is notified, because this could indicate an adverse effect. Difficulty urinating is an adverse effect and indicates urinary retention; this should also be reported.

**Test-Taking Strategy:** Focus on the subject, side and adverse effects of amitriptyline. Recalling that constipation is a side effect of this medication will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Psychotherapeutics: Tricyclic antidepressants

**Health Problem:** Mental Health: Mood Disorders

**Priority Concepts:** Client Education; Safety

846. **Answer:** 4

**Rationale:** Risperidone can cause orthostatic hypotension. Sunlight should be avoided by the client taking this medication. With any psychotropic medication, caution needs to be taken (such as with driving or other activities requiring
alertness) until the individual can determine whether her or his level of alertness is affected. Food interaction is not a concern.

**Test-Taking Strategy:** Focus on the **subject**, parameters to monitor for the client taking risperidone. It is necessary to know the nursing considerations related to the administration of risperidone and that risperidone can cause orthostatic hypotension. Also, use of the **ABCs—airway, breathing, circulation**—will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Psychotherapeutics: Antipsychotics

**Health Problem:** Mental Health: Schizophrenia

**Priority Concepts:** Client Education; Safety

847. **Answer:** 2

**Rationale:** The maximum therapeutic effects of imipramine may not occur for 2 to 3 weeks after antidepressant therapy has been initiated. Options 1, 3, and 4 are incorrect time periods.

**Test-Taking Strategy:** Note the **subject**, the desired effect of this medication, and focus on the word *maximum*. Recalling that it takes 2 to 3 weeks for a maximum therapeutic effect to occur with most antidepressants will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Psychotherapeutics: Tricyclic Antidepressants

**Health Problem:** Mental Health: Mood Disorders

**Priority Concepts:** Anxiety; Client Education

848. **Answer:** 3, 5

**Rationale:** With MAOIs, the client should avoid ingesting foods that are high in tyramine. Ingestion of these foods could trigger a potentially fatal hypertensive crisis. Foods to avoid include yogurt; aged cheeses; smoked or processed meats; red wines; and fruits such as avocados, raisins, or figs.

**Test-Taking Strategy:** Focus on the **subject**, acceptable food items while taking MAOIs. Recall that phenelzine is an MAOI and that foods high in tyramine needed to be avoided. Next, from the food items listed in the question, identify the foods that are tyramine-free.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Psychotherapeutics: Monoamine Oxidase Inhibitors (MAOIs)
**Health Problem:** Mental Health: Mood Disorders  
**Priority Concepts:** Nutrition; Safety  

849. **Answer:** 2

**Rationale:** Tardive dyskinesia is a reaction that can occur from antipsychotic medication. It is characterized by uncontrollable involuntary movements of the body and extremities, particularly the tongue. Parkinsonism is characterized by tremors, mask-like facies, rigidity, and a shuffling gait. Hypertensive crisis can occur from the use of monoamine oxidase inhibitors and is characterized by hypertension, occipital headache radiating frontally, neck stiffness and soreness, nausea, and vomiting. Neuroleptic malignant syndrome is a potentially fatal syndrome that may occur at any time during therapy with neuroleptic (antipsychotic) medications. It is characterized by dyspnea or tachypnea, tachycardia or irregular pulse rate, fever, blood pressure changes, increased sweating, loss of bladder control, and skeletal muscle rigidity.

**Test-Taking Strategy:** Focus on the subject, a complication of antipsychotic medications. To direct you to the correct option, remember that tardive dyskinesia is characterized by uncontrollable involuntary movements of the body and extremities, particularly the tongue.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Psychotherapeutics: Antipsychotics  
**Health Problem:** Mental Health: Mood Disorders  
**Priority Concepts:** Clinical Judgment; Psychosis  

850. **Answer:** 2

**Rationale:** The most common side and adverse effects related to fluoxetine include central nervous system and gastrointestinal system dysfunction. Fluoxetine affects the gastrointestinal system by causing nausea and vomiting, cramping, and diarrhea. Cardiovascular symptoms, dry mouth, and excessive sweating are not side and adverse effects associated with this medication.

**Test-Taking Strategy:** Focus on the subject, common side and adverse effects of fluoxetine. It is necessary to remember that this medication causes gastrointestinal problems. This will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Pharmacology: Psychotherapeutics: Selective Serotonin Reuptake Inhibitors (SSRIs)  
**Health Problem:** Mental Health: Mood Disorders  
**Priority Concepts:** Clinical Judgment; Safety  
Rationale: Buspirone is not recommended for the treatment of paranoid thought disorders, drug or alcohol withdrawal, or schizophrenia. Buspirone most often is indicated for the treatment of anxiety.

Test-Taking Strategy: Note the strategic word, effective. Note the words absence of which manifestation in the question. Recalling that buspirone is an antianxiety medication will direct you to the correct option.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Pharmacology: Psychotherapeutics: Antianxiety/Anxiolytics
Health Problem: Mental Health: Anxiety Disorder
Priority Concepts: Anxiety; Evidence

Rationale: Maintenance serum levels of lithium are 0.6 to 1.2 mEq/L (0.6 to 1.2 mmol/L). Symptoms of toxicity begin to appear at levels of 1.5 mEq/L (1.5 mmol/L). Lithium toxicity requires immediate medical attention and the primary health care provider is notified if symptoms of toxicity occur.

Test-Taking Strategy: Focus on the subject, therapeutic serum medication level of lithium. Recalling that the high end of the maintenance level is 1.2 mEq/L (1.2 mmol/L) will direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Planning
Content Area: Pharmacology: Psychotherapeutics: Mood Stabilizers
Health Problem: Mental Health: Mood Disorders
Priority Concepts: Clinical Judgment; Safety

Rationale: Clomipramine is a tricyclic antidepressant used to treat obsessive-compulsive disorder. Sedation sometimes occurs. Insomnia seldom is a side effect. Weight gain and tachycardia are side and adverse effects of this medication.

Test-Taking Strategy: Focus on the subject, noncompliance with clomipramine. Recalling that this medication is a tricyclic antidepressant used to treat obsessive-compulsive disorder will direct you to the correct option.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Pharmacology: Psychotherapeutics: Tricyclic Antidepressants
Health Problem: Mental Health: OCD
Priority Concepts: Adherence; Evidence

854. **Answer:** 2

**Rationale:** Seizure activity can occur in clients taking bupropion dosages greater than 450 mg daily. Weight gain is an occasional side effect, whereas constipation is a common side effect of this medication. This medication does not cause significant orthostatic blood pressure changes.

**Test-Taking Strategy:** Focus on the **subject**, signs of toxicity associated with bupropion. Note the words *excessive amount*. These words will direct you to the correct option, the one that identifies the most serious concern.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Pharmacology: Psychotherapeutics: Atypical Antidepressant

**Health Problem:** Mental Health: Mood Disorders

**Priority Concepts:** Clinical Judgment; Safety

855. **Answer:** 3

**Rationale:** Depressed individuals sleep for long periods, are unable to go to work, and feel as if they cannot “do anything.” When these clients have had some therapeutic effect from their medication, they report resolution of many of these complaints and exhibit an improvement in their appearance. Options 1, 2, and 4 identify continued depression.

**Test-Taking Strategy:** The client’s behaviors or reports identified in options 1, 2, and 4 are **comparable or alike** and are symptoms of depression. The improvement in appearance indicates a therapeutic response to the medication, indicating compliance with the medication regimen.

**Level of Cognitive Ability:** Evaluating

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Evaluation

**Content Area:** Pharmacology: Psychotherapeutics: Tricyclic Antidepressants

**Health Problem:** Mental Health: Mood Disorders

**Priority Concepts:** Adherence; Evidence

Introduction

Pyramid to Success
Pyramid points focus on intravenous (IV) therapies, including intravenous fluids and parenteral nutrition, administration of blood products, care of the client with a tube, and complex problems involving the integumentary, hematological, oncological, endocrine, gastrointestinal, respiratory, cardiovascular, renal and urinary, neurological, and immune systems. The different types of shock are discussed with a special focus on sepsis, systemic inflammatory response syndrome, multiple organ dysfunction syndrome, septic shock, and hemodynamic management. Sedation, agitation, and delirium are discussed. These concepts are potential topics on the NCLEX®. With regard to IV therapy, assessment of the client for allergies, including latex sensitivity, before initiation of an IV line and monitoring for complications are critical nursing responsibilities. Likewise, the procedure for administering blood components, the signs and symptoms of transfusion reaction, and the immediate interventions if a transfusion reaction occurs are a focus. Care of the client with a tube such as a gastrointestinal tube or chest tube have varying indications and associated nursing interventions. Specific problems requiring a high-level of nursing care for complex conditions are discussed in detail, as well as the associated assessment findings and nursing interventions.

Client Needs: Learning Objectives

Safe and Effective Care Environment

- Applying principles of infection control
- Collaborating with interprofessional health care members in the care of a client with a complex condition
- Ensuring that informed consent has been obtained for invasive procedures and for the administration of blood products
- Establishing priorities of assessments and interventions
- Following guidelines regarding the use of invasive devices
- Handing hazardous and infectious materials to prevent injury to health care personnel and others
- Identifying the client with at least 2 forms of identification (e.g., name and date of birth) prior to the administration of a blood product
- Maintaining confidentiality
- Maintaining precautions to prevent errors, accidents, and injury
- Protecting the medicated client from injury
Using equipment safely
Using standard and transmission-based precautions and asepsis procedures

Health Promotion and Maintenance

Assessing the client’s ability to perform self-care
Considering lifestyle choices related to home care of the IV line
Identifying lifestyle choices related to receiving a blood transfusion
Providing client and family education regarding the administration of parenteral nutrition at home
Providing health and wellness teaching to prevent complications
Teaching the client about prescribed medications or IV therapy
Teaching the client and family about care of the IV line
Teaching the client to monitor for signs and symptoms that indicate the need to notify the primary health care provider

Psychosocial Integrity

Assessing the client and family emotional response to treatment
Discussing role changes and alterations in lifestyle related to the client’s need to receive IV therapy or parenteral nutrition
Facilitating client and family coping
Identifying support systems
Identifying cultural, religious, and spiritual factors influencing health
Keeping the family informed of client progress
Providing emotional support to significant others
Promoting an environment that will allow the client to express concerns

Physiological Integrity

Administering blood products safely
Administering medications and IV therapy safely
Assessing and caring for central venous access devices
Assessing for expected and unexpected effects of interventions and documenting findings
Assessing the mobility and immobility level of the client
Assisting the client with activities of daily living
Documenting the client’s response to complex care interventions
Handling medical emergencies
Identifying client allergies and sensitivities
Identifying the adverse effects of and contraindications to medication or IV therapy
Initiating nursing interventions when medical or surgical complications arise
Managing a client with a burn or inhalation injury
Managing a client with a cardiovascular problem
Managing a client with a gastrointestinal problem
Managing a client with a hematological or oncological problem
Managing a client with a respiratory problem
Managing a client with an endocrine problem
Managing a client with renal and urinary problem.
Managing a client with sepsis, systemic inflammatory response syndrome, multiple organ dysfunction syndrome, and septic shock
Managing a client with a neurological problem
Managing a client with an immune problem
Managing sedation, agitation, and delirium safely
Managing hemodynamic changes in a critically ill client
Managing medication emergencies if a transfusion reaction or other complication occurs
Monitoring for alterations in body systems
Monitoring of enteral feedings and the client’s ability to tolerate feedings
Monitoring the client with an invasive device such as a chest tube and responding to changes in condition as necessary
Preparing for diagnostic tests to confirm accurate placement of a tube
Providing interventions compatible with the client’s age, cultural, religious, spiritual and health care beliefs, education level, and language
Recognizing changes in the client’s condition that indicate a potential complication and intervening appropriately
Using special and invasive monitoring equipment
CHAPTER 69

Complex Care

http://evolve.elsevier.com/Silvestri/comprehensiveRN/

Priority Concepts
Clinical Judgment, Perfusion

I. Administration of Intravenous (IV) Fluids
   A. Intravenous Therapy
      1. Used to sustain clients who are unable to take substances orally
      2. Replaces water, electrolytes, and nutrients more rapidly than oral administration
      3. Provides immediate access to the vascular system for the rapid delivery of specific solutions without the time required for gastrointestinal tract absorption
      4. Provides a vascular route for the administration of medication or blood components
   B. Types of solutions (Table 69-1)

   Lactated Ringer’s solution contains potassium and should not be administered to clients with acute kidney injury or chronic kidney disease.

   1. Isotonic solutions
      a. Have the same osmolality as body fluids
      b. Increase extracellular fluid volume
      c. Do not enter the cells because no osmotic force exists to shift the fluids
   2. Hypotonic solutions
      a. Are more dilute solutions and have a lower osmolality than body fluids
      b. Cause the movement of water into cells by osmosis
      c. Should be administered slowly to prevent cellular edema
   3. Hypertonic solutions
      a. Are more concentrated solutions and have a higher osmolality than body fluids
b. Cause movement of water from cells into the extracellular fluid by osmosis

4. Colloids
   a. Also called plasma expanders
   b. Pull fluid from the interstitial compartment into the vascular compartment
   c. Used to increase the vascular volume rapidly, such as in hemorrhage or severe hypovolemia

Administration of an intravenous (IV) solution or medication provides immediate access to the vascular system. This is a benefit of administering solutions or medications via this route, but it can also present a risk. Therefore, it is critical to ensure that the primary health care provider's (PHCP's) prescriptions are checked carefully and that the correct solution or medication is administered as prescribed. Always follow the rights for medication administration.

C. Intravenous devices
   1. Butterfly sets
      a. The set is a wing-tip needle with a metal cannula, plastic or rubber wings, and a plastic catheter or hub.
      b. The needle is 0.5 to 1.5 inches in length, with needle gauge sizes from 16 to 26.
      c. Infiltration is more common with these devices.
      d. The butterfly infusion set is used commonly in children and older clients, whose veins are likely to be small or fragile.

D. IV gauges
   1. The gauge refers to the diameter of the lumen of the needle or cannula.
   2. The smaller the gauge number, the larger the diameter of the lumen; the larger the gauge number, the smaller the diameter of the lumen.
   3. The size of the gauge used depends on the solution to be administered and the diameter of the available vein.
4. Large-diameter lumens (smaller gauge numbers) allow a higher fluid rate than do smaller-diameter lumens and allow the administration of higher concentrations of solutions.

5. For rapid emergency fluid administration, blood products, or anesthetics, preoperative and postoperative clients, large-diameter lumens are used, such as an 18- or 19-gauge lumen.

6. For peripheral fat emulsion (lipids) infusions, a 20- or 21-gauge lumen or cannula is used.

7. For standard IV fluid and clear liquid IV medications, a 22- or 24-gauge lumen or cannula is used.

8. If the client has very small veins, a 24- to 25-gauge lumen or cannula is used.

A client with diabetes mellitus usually does not receive dextrose (glucose) solutions, because the solution can increase the blood glucose level.

E. IV containers

1. Container is usually plastic; some solutions are in glass containers.

2. Squeeze the plastic bag to ensure intactness and assess the glass bottle for any cracks before hanging.

3. In most agencies, the pharmacy department prepares solutions containing medication; in some situations the nurse needs to reconstitute the medication. Agency protocol and pharmacy instruction should always be followed.

Do not write on a plastic IV bag with a marking pen, because the ink may be absorbed through the plastic into the solution. Use a label and a ballpoint pen for writing on the label, placing the label onto the bag.

F. IV tubing (Fig. 69-1)

1. IV tubing contains a spike end for the bag or bottle, drip chamber, roller clamp, Y site, and adapter end for attachment to the cannula that is inserted into the client’s vein.

2. Shorter, secondary tubing is used for piggyback solutions, connecting them to the injection sites nearest to the drip chamber (Fig. 69-2).

3. Special tubing is used for medication that absorbs into plastic (check specific medication administration
guidelines when administering IV medications).

4. Vented and nonvented tubing are available.
   a. A vent allows air to enter the IV container as the fluid leaves.
   b. A vented adapter can be used to add a vent to a nonvented IV tubing system.
   c. Use nonvented tubing for flexible containers.
   d. Use vented tubing for glass or rigid plastic containers to allow air to enter and displace the fluid as it leaves; fluid will not flow from a rigid IV container unless it is vented.

G. Drip chambers (Fig. 69-3)
   1. Macrodrip chamber
      a. The chamber is used if the solution is thick or is to be infused rapidly.
      b. The drop factor varies from 10 to 20 drops (gtt)/mL, depending on the manufacturer.
      c. Read the tubing package to determine how many drops per milliliter are delivered (drop factor).
   2. Microdrip chamber
      a. Normally, the chamber has a short vertical metal piece (stylet) where the drop forms.
      b. The chamber delivers about 60 gtt/mL.
      c. Read the tubing package to determine the drop factor (gtt/mL).
      d. Microdrip chambers are used if fluid will be infused at a slow rate (less than 50 mL/hr) or if the solution contains potent medication that needs
to be titrated, such as in a critical care setting or in pediatric clients.

H. Filters

1. Filters provide protection by preventing particles from entering the client’s veins.
2. They are used in IV lines to trap small particles such as undissolved substances, or medications that have precipitated in solution.
3. Check the agency policy regarding the use of filters.
4. A 0.22-µm filter is used for most solutions; a 1.2-µm filter is used for solutions containing lipids or albumin; and a special filter is used for blood components.
5. Change filters every 24 to 72 hours (depending on agency policy) to prevent bacterial growth.

I. Needleless infusion devices

1. Needleless infusion devices include recessed needles, plastic cannulas, and 1-way valves; these systems decrease the exposure to contaminated needles.
2. Do not administer parenteral nutrition or blood products through a 1-way valve.

J. Intermittent infusion devices

1. Intermittent infusion devices are used when intravascular accessibility is desired for intermittent administration of medications by IV push or IV piggyback.
2. Patency is maintained by periodic flushing with normal saline solution (*sodium chloride* and *normal saline* are interchangeable names).
3. Depending on agency policy, when administering medication, flush with 1 to 2 mL of normal saline to confirm placement of the IV cannula; administer the prescribed medication and then flush the cannula again with 1 to 2 mL of normal saline to maintain patency.

K. Electronic IV infusion devices

1. IV infusion pumps control the amount of fluid infusing and should be used with central venous lines, arterial lines, solutions containing medication, and parenteral nutrition infusions. Most agencies use IV pumps for the infusion of any IV solution.
2. A syringe pump is used when a small volume of
medication is administered; the syringe that contains
the medication and solution fits into a pump and is
set to deliver the medication at a controlled rate.

3. Patient-controlled analgesia (PCA)
   a. A device that allows the client to self-administer IV medication, such as an
      analgesic; the client can administer doses at set intervals, and the pump
can be set to lock out doses that are not
within the preset time frame to prevent overdose.
   b. The PCA regimen may include a basal rate of infusion along with the demand
dosing, basal rate infusion alone, or
demand dosing alone.
   c. A bolus dose can be given prior to any
   of the settings and should be set based
   on the PHCP’s prescription.
   d. PCAs are always kept locked, and
   setup requires the witness of another
   registered nurse (RN).

L. Latex allergy
   1. Assess the client for an allergy to latex.
   2. IV supplies, including IV catheters, IV tubing, IV ports
      (particularly IV rubber injection ports), rubber
      stoppers on multidose vials, and adhesive tape, may
      contain latex.
   3. Latex-safe IV supplies need to be used for clients with
   a latex allergy; most agencies carry these type of
   supplies, but this still needs to be checked.
   4. See Chapter 62 for additional information regarding
   latex allergy.

M. Selection of a peripheral IV site
   1. Veins in the hand, forearm, and antecubital fossa are
suitable sites (Fig. 69-4).
   2. Veins in the lower extremities (legs and feet)
are not suitable for an adult client because of the risk
of thrombus formation and the possible pooling of
medication in areas of decreased venous return (Box
3. Veins in the scalp and feet may be suitable sites for infants.
4. Assess the veins of both arms closely before selecting a site.
5. Start the IV infusion distally to provide the option of proceeding up the extremity if the vein is ruptured or infiltration occurs; if infiltration occurs from the antecubital vein, the lower veins in the same arm usually should not be used for further puncture sites.
6. Determine the client’s dominant side, and select the opposite side for a venipuncture site.
7. Bending the elbow on the arm with an IV may easily obstruct the flow of solution, causing infiltration that could lead to thrombophlebitis.
8. Avoid checking the blood pressure on the arm receiving the IV infusion if possible.
9. Do not place restraints over the venipuncture site.
10. Use an armboard as needed when the venipuncture site is located in an area of flexion.

In an adult, the most frequently used sites for inserting an IV cannula or needle are the veins of the forearm, because the bones of the forearm act as a natural support and splint.

N. Initiation and administration of IV solutions

1. Check the IV solution against the PHCP’s prescription for the type, amount, percentage of solution, and rate of flow; follow the rights for medication administration.
2. Assess the health status and medical disorders of the client and identify client conditions that contraindicate use of a particular IV solution or IV equipment, such as an allergy to cleansing solution, adhesive materials, or latex. Check compatibility of IV solutions as appropriate.
3. Check client’s identification by 2 identifiers and explain the procedure to the client; assess client’s previous experience with IV therapy and preference for insertion site.
4. Wash hands thoroughly before inserting an IV line and before working with an IV line; wear gloves.
5. Use sterile technique when inserting an IV line and when changing the dressing over the IV site.
6. Change the venipuncture site every 72 to 96 hours in accordance with Centers for Disease Control and
Prevention (CDC) recommendations and agency policy.
7. Change the IV dressing when the dressing is wet or contaminated, or as specified by the agency policy.
8. Change the IV tubing every 96 hours in accordance with CDC recommendations and agency policy or with a change of the venipuncture site.
9. Do not let an IV bag or bottle of solution hang for more than 24 hours, to diminish the potential for bacterial contamination and possibly sepsis.
10. Do not allow the IV tubing to touch the floor, to prevent potential bacterial contamination.
11. See Priority Nursing Actions for instructions on inserting an IV.
12. See Priority Nursing Actions for instructions on removing an IV.

Priority Nursing Actions

Inserting a Peripheral Intravenous Line

1. Check the primary health care provider’s (PHCP’s) prescription, determine the type and size of infusion device, and prepare intravenous (IV) tubing or extension set and solution; prime IV tubing or extension set to remove air from the system; explain procedure to the client.
2. Select the vein for insertion based on vein quality, client size, and indication of IV therapy; apply tourniquet and palpate the vein for resilience (see Fig. 69-4).
3. Clean the skin with an antimicrobial solution, using an inner to outer circular motion, or as specified by the Centers for Disease Control and Prevention (CDC) guidelines and agency policy.
4. Stabilize the vein below the insertion site and puncture the skin and vein, observing for blood in the flashback chamber; when observed, lower the catheter so that it is flush with the skin and advance the catheter into the vein (if unsuccessful, a new sterile device is used for the next attempt at insertion).
5. Remove the tourniquet. Apply pressure above the insertion site with the middle finger of the nondominant hand and retract the stylet from the catheter; connect the end of the IV tubing or extension set to the catheter tubing, secure it, and begin IV flow. Ask the client about comfort at the site and assess site for adequate flow.
6. Tape and secure insertion site with a transparent dressing as specified by agency procedure; label the tubing, dressing, and solution bags clearly, indicating the date and time.
7. Document the specifics about the procedure such as number of attempts at insertion; the insertion site, type and size of device, solution and flow rate, and time; and the client’s response. In addition, follow agency procedure for documentation of procedure.

Reference

2395
Priority Nursing Actions

Removing a Peripheral Intravenous Line

1. Check the primary health care provider’s (PHCP’s) prescription and explain the procedure to the client; ask the client to hold the extremity still during cannula or needle removal.
2. Turn off the intravenous (IV) tubing clamp and remove the dressing and tape covering the site, while stabilizing the catheter.
3. Apply light pressure with sterile gauze or other material as specified by agency procedure over the site and withdraw the catheter using a slow, steady movement, keeping the hub parallel to the skin.
4. Apply pressure for 2 to 3 minutes, using dry sterile gauze (apply pressure for a longer period of time if the client has a bleeding disorder or is taking anticoagulant medication).
5. Inspect the site for redness, drainage, or swelling; check the catheter for intactness.
6. Apply a dressing as needed per agency policy.
7. Document the procedure and the client’s response.

Reference

O. Precautions for IV lines

1. On insertion, an IV line can cause initial pain and discomfort for the client.
2. An IV puncture provides a route of entry for microorganisms into the body.
3. Medications administered by the IV route enter the blood immediately, and any adverse reactions or allergic responses can occur immediately.
4. Fluid (circulatory) overload or electrolyte imbalances can occur from excessive or too rapid infusion of IV fluids.
5. Incompatibilities between certain solutions and medications can occur.

Clients with respiratory, cardiac, renal, or liver disease; older clients; and very young persons are at risk for circulatory overload and cannot tolerate an excessive fluid volume. Also, a client with heart failure or renal failure usually is not given a solution containing saline, because this type of fluid promotes the retention of water and would therefore exacerbate heart failure or renal failure by increasing the fluid overload.
P. Complications of intravenous therapy (Table 69-2)

Always document the occurrence of a complication, assessment findings, actions taken, and the client’s response according to agency policy.

Q. Central venous catheters

1. Description
   a. Central venous catheters (Fig. 69-5) are used to deliver hyperosmolar solutions, measure central venous pressure, infuse parenteral nutrition, or infuse multiple IV solutions or medications.
   b. Catheter position is determined by radiography after insertion.
   c. The catheter may have a single, double, or triple lumen.
   d. The catheter may be inserted peripherally and threaded through the basilic or cephalic vein into the superior vena cava, inserted centrally through the internal jugular or subclavian veins, or surgically tunneled through subcutaneous tissue.
   e. With multilumen catheters, more than 1 medication can be administered at the same time without incompatibility problems, and only 1 insertion site is present.

   For central line insertion, tubing change, and line removal, place the client in the Trendelenburg’s position if not contraindicated or in the supine position, and instruct the client to perform the Valsalva maneuver to increase pressure in the central veins when the IV system is open.

2. Tunneled central venous catheters
   a. A more permanent type of catheter, such as the Hickman, Broviac, or Groshong catheter, is used for long-term IV therapy.
   b. The catheter may be single lumen or multilumen.
   c. The catheter is inserted in the operating
room, and the catheter is threaded into the lower part of the vena cava at the entrance of the right atrium (entrance site) and tunneled under the skin to the exit site where the catheter comes out of the chest; the catheter at the exit site is secured by means of a “cuff” just under the skin at the exit site.

d. The catheter is fitted with an intermittent infusion device to allow access as needed and to keep the system closed and intact.

e. Patency is maintained by flushing with a diluted heparin solution or normal saline solution, depending on the type of catheter, per agency policy.

3. Vascular access ports (implantable port)
a. Surgically implanted under the skin, ports such as a Port-a-Cath, Mediport, or Infusaport are used for long-term administration of repeated IV therapy.
b. For access, the port requires palpation and injection through the skin into the self-sealing port with a noncoring needle, such as a Huber point needle.
c. Patency is maintained by periodic flushing with a diluted heparin solution as prescribed and as per agency policy.

d. Phlebitis is a common complication.

4. Peripherally inserted central catheter (PICC) line
a. The catheter is used for long-term IV therapy, frequently in the home.
b. The basilic vein usually is used, but the median cubital and cephalic veins in the antecubital area also can be used.
c. The catheter is threaded so that the catheter tip may terminate in the subclavian vein or superior vena cava.
d. A small amount of bleeding may occur at the time of insertion and may continue for 24 hours, but bleeding thereafter is not expected.
e. Phlebitis is a common complication.

R. Epidural Catheter (Fig. 69-6)
1. Catheter is placed in the epidural space for the administration of analgesics; this method of
administration reduces the amount of medication needed to control pain; therefore, the client experiences fewer side effects.

2. Assess client’s vital signs, level of consciousness, and motor and sensory function of the lower extremities.

3. Monitor insertion site for signs of infection and be sure that the catheter is secured to the client’s skin and that all connections are taped to prevent disconnection.

4. Check PHCP’s prescription regarding solution and medication administration.

5. For continuous infusion, monitor the electronic infusion device for proper rate of flow.

6. For bolus dose administration, follow the procedure for administering bolus doses through the catheter and follow agency procedure.

7. Aspiration is done before injecting medication; if more than 1 mL of clear fluid or blood returns, the medication is not injected and the PHCP or anesthesiologist is notified immediately (catheter may have migrated into the subarachnoid space or a blood vessel).

Contraindications to an epidural catheter and administration of epidural analgesia include skeletal and spinal abnormalities, bleeding disorders, use of anticoagulants, history of multiple abscesses, and sepsis.

II. Administration of Parenteral Nutrition

A. Parenteral Nutrition (PN)

1. Description

a. Parenteral nutrition supplies nutrients via the veins.

b. PN consists of both partial parenteral nutrition (PPN) and total parenteral nutrition (TPN). The indication of the type used depends on the client’s nutritional needs.

c. PN supplies carbohydrates in the form of dextrose, fats in an emulsified form, proteins in the form of amino acids, vitamins, minerals, electrolytes, and water.

d. PN prevents subcutaneous fat and muscle protein from being catabolized by the body for energy.
e. PN solutions are hypertonic due to the higher concentrations of glucose and addition of amino acids.

2. Indications
   a. Clients with severely dysfunctional or nonfunctional gastrointestinal tracts who are unable to process nutrients may benefit from PN.
   b. Clients who can take some oral nutrition but not enough to meet their nutrient requirements may benefit from PN.
   c. Clients with multiple gastrointestinal surgeries, gastrointestinal trauma, severe intolerance to enteral feedings, or intestinal obstructions, or who need to rest the bowel for healing, may benefit from PN.
   d. Clients with severe nutritionally deficient conditions such as acquired immunodeficiency syndrome, cancer, burn injuries, or malnutrition, or clients receiving chemotherapy, may benefit from PN.

![Warning]

PN is a form of nutrition and is used when there is no other nutritional alternative. Administering nutrition orally or through a nasogastric tube is usually initiated first, before PN is initiated.

3. Administration of PN (Fig. 69-7).
4. PPN
   a. Usually administered through a large distal vein in the arm with a standard peripheral IV catheter or midline or through a PICC. A midline is placed in an upper arm vein such as the brachial or cephalic vein with the tip ending below the level of the axillary line.
   b. If a PICC cannot be established, the subclavian vein or internal or external jugular veins can be used for PPN.

5. TPN
   a. Administered through a central vein; the use of a PICC is acceptable. Other sites that can be used include the subclavian vein and the internal or
external jugular veins.

b. If the bag of intravenous solution (the TPN) is empty and the nurse is waiting for the delivery of a new bag of solution from the pharmacy, a 10% dextrose in water solution should be infused at the prescribed rate to prevent hypoglycemia; the prescribed solution should be obtained as soon as possible.

The delivery of hypertonic solutions into peripheral veins can cause sclerosis, phlebitis, or swelling. Monitor closely for these complications.

6. Components of parenteral nutrition
   a. Carbohydrates: The strength of the dextrose solution depends on the client’s nutritional needs, the route of administration (central or peripheral), and agency protocols; carbohydrates typically provide 60% to 70% of calorie (energy) needs.
   b. Amino acids (protein): Concentrations range from 3.5% to 20%. Lower concentrations are most commonly used for peripheral vein administration, and higher concentrations are most often administered through a central vein; about 15% to 20% of total energy needs should come from protein.

7. Fat emulsion (lipids)
   a. Lipids provide up to 30% of calorie (energy) needs.
   b. Lipids provide nonprotein calories and prevent or correct fatty acid deficiency.
   c. Lipid solutions are isotonic and therefore can be administered through a peripheral or central vein; the solution may be administered through a separate IV line below the filter of the main IV administration set by a Y-connector, or as an admixture to the PN solution (3-in-1 admixture consisting of dextrose, amino acids,
d. Most fat emulsions are prepared from soybean or safflower oil, with egg yolk to provide emulsification; the primary components are linoleic, oleic, palmitic, linolenic, and stearic acids (assess the client for allergies).

e. Glucose-intolerant clients or clients with diabetes mellitus may benefit from receiving a larger percentage of their PN from lipids, which helps control blood glucose levels and lower insulin requirements caused by infused dextrose.

f. Examine the bottle for separation of emulsion into layers or fat globules or for the accumulation of froth; if observed, do not use and return the solution to the pharmacy.

g. Additives should not be put into the fat emulsion solution.

h. Follow agency policy regarding the filter size that should be used; usually a 1.2-µm filter or larger should be used, because the lipid particles are too large to pass through a 0.22-µm filter.

i. Infuse solution at the flow rate prescribed—usually slowly at 1 mL/minute initially—monitor vital signs every 10 minutes, and observe for adverse reactions for the first 30 minutes of the infusion. If signs of an adverse reaction occur, stop the infusion and notify the primary health care provider (PHCP) (Box 69-2).

j. If no adverse reaction occurs, adjust the flow rate to the prescribed rate.

k. Monitor serum lipids 4 hours after discontinuing the infusion.

8. Other components

a. PN solutions usually contain a standard multivitamin preparation to meet most vitamin needs and prevent...
deficiencies.
b. Individual vitamin preparations can be added, as needed and as prescribed.
c. Minerals and trace elements:
Commercial mineral and trace element preparations are available in various concentrations to promote normal metabolism.
d. Electrolytes: Electrolyte requirements for individuals receiving PN therapy vary, depending on body weight, presence of malnutrition or catabolism, degree of electrolyte depletion, changes in organ function, ongoing electrolyte losses, and the disease process.
e. Water: The amount of water needed in a PN solution is determined by electrolyte balance and fluid requirements.
f. Regular insulin: May be added to control the blood glucose level because of the high concentration of glucose in the PN solution.
g. Heparin: May be added to reduce the buildup of a fibrinous clot at the catheter tip.

B. Administration and discontinuation
1. Continuous PN
   a. Infused continuously over 24 hours
   b. Most commonly used in a hospital setting

2. Intermittent or cyclic PN
   a. In general, the nutrient solution infusion regimen varies and is commonly administered overnight.
   b. Allows clients requiring PN on a long-term basis to participate in activities of daily living during the day without the inconvenience of an IV bag and pump set.
   c. Monitor glucose levels closely because of the risk of hypoglycemia due to lack of glucose during
3. Discontinuing PN therapy

a. Evaluation of nutritional status by a nutritionist is done before PN is discontinued.
b. If discontinuation is prescribed, gradually decrease the flow rate for 1 to 2 hours while increasing oral intake (this assists in preventing hypoglycemia).
c. After removal of the IV catheter, change the dressing daily until the insertion site heals. Note that central lines should not be left in without a reason due to risk of infection, but in some situations are left in place and used for another necessary reason (venous access, medication administration).
d. Encourage oral nutrition.
e. Record oral intake, body weight, and laboratory results of serum electrolyte and glucose levels.

Abrupt discontinuation of a PN solution can result in hypoglycemia. The flow rate should be decreased gradually when the PN is discontinued.

C. Complications (Table 69-3)

1. Pneumothorax and air embolism are associated with central line placement; air embolism is also associated with tubing changes.
2. Other complications include infection (catheter-related), hypervolemia, and metabolic alterations such as hyperglycemia and hypoglycemia; these complications are usually caused by the PN solution itself (see Priority Nursing Actions).

Priority Nursing Actions

Central Venous Catheter Site with a Suspected Infection
1. Notify the primary health care provider (PHCP).
2. Prepare to remove the catheter and for possible restart at a different location.
3. Remove the tip of the catheter and send it to the laboratory for culture if prescribed by the PHCP.
D. Additional nursing considerations

1. Check the PN solution with the PHCP’s prescription to ensure that the prescribed components are contained in the solution; some health care agencies require validation of the prescription by 2 registered nurses.

2. To prevent infection and solution incompatibility, IV medications and blood are not given through the PN line.

3. Blood for testing may be drawn from the central venous access site; a port other than the port used to infuse the PN is used for blood draws after the PN has been stopped for several minutes (per agency procedure), because the PN solution can alter the results of the sample. The client with a central venous access site receiving PN should still have a venipuncture site.

4. Monitor partial thromboplastin time and prothrombin time for clients receiving anticoagulants.

5. Monitor electrolyte and albumin levels and liver and renal function studies, as well as any other prescribed laboratory studies. Blood studies for blood chemistries are normally done every other day or 3 times per week (per agency procedures) when the client is receiving PN; the results are the basis for the PHCP continuing or changing the PN solution or rate.

6. Monitor blood glucose levels as prescribed (usually every 4 hours) because of the risk for hyperglycemia from the PN solution components.

7. In severely dehydrated clients, the albumin level may drop initially after initiating PN because the treatment restores hydration.

8. With severely malnourished clients, monitor for “refeeding syndrome” (a rapid drop in potassium, magnesium, and phosphate serum levels).

9. The electrolyte shift that occurs in “refeeding syndrome” can cause cardiovascular, respiratory, and neurological problems; monitor for shallow respirations, confusion, weakness, bleeding
tendencies, and seizures. If noted, the PHCP is notified immediately.

10. Abnormal liver function values may indicate intolerance to or an excess of fat emulsion or problems with metabolism with glucose and protein.

11. Abnormal renal function tests may indicate an excess of amino acids.

12. PN solutions should be stored under refrigeration and administered within 24 hours from the time they are prepared (remove from refrigerator 0.5 to 1 hour before use).

13. PN solutions that are cloudy or darkened should not be used and should be returned to the pharmacy.

14. Additions of substances such as nutrients to PN solutions should be made in the pharmacy and not on the nursing unit.

15. Consultation with the nutritionist should be done on a regular basis (as prescribed or per agency protocol).

E. Home care instructions (Box 69-3)

III. Administration of Blood Products

A. Blood products

1. Packed red blood cells (PRBCs)

   a. PBRCs are a blood product used to replace erythrocytes; infusion time for 1 unit is usually between 2 and 4 hours.

   b. Each unit increases the hemoglobin level by 1 g/dL (10 mmol/L) and hematocrit by 3% (0.03); the change in laboratory values takes 4 to 6 hours after completion of the blood transfusion.

   c. Evaluation of an effective response is based on the resolution of the symptoms of anemia and an increase in the erythrocyte, hemoglobin, and hematocrit count.

   d. Leukocyte-poor or leukocyte-depleted units are units in which leukocytes, proteins, and plasma have been reduced. They are used to restore oxygen-carrying capacity of blood and intravascular volume.

   Washed red blood cells (depleted of
plasma, platelets, and leukocytes) may be prescribed for a client with a history of allergic transfusion reactions or those who underwent hematopoietic stem cell transplant. Leukocyte depletion (leukoreduction) by filtration, washing, or freezing is the process used to decrease the amount of white blood cells (WBCs) in a unit of packed cells.

2. Platelet transfusion
   a. Platelets are used to treat thrombocytopenia and platelet dysfunctions.
   b. Clients receiving multiple units of platelets can become “alloimmunized” to different platelet antigens. These clients may benefit from receiving only platelets that match their specific human leukocyte antigen (HLA).
   c. Crossmatching is not required but usually is done (platelet concentrates contain few red blood cells [RBCs]).
   d. The volume in a unit of platelets may vary; always check the bag for the volume of the blood component (in milliliters).
   e. Platelets are administered immediately upon receipt from the blood bank and are given rapidly, usually over 15 to 30 minutes.
   f. Evaluation of an effective response is based on improvement in the platelet count, and platelet counts normally are evaluated 1 hour and 18 to 24 hours after the transfusion; for each unit of platelets administered, an increase of 5000 to 10,000 mm$^3$ (5 to 10 $\times$ 10$^9$/L) is expected.

3. Fresh-frozen plasma
   a. Fresh-frozen plasma may be used to provide clotting factors or volume expansion; it contains no platelets.
   b. Fresh-frozen plasma is infused within 2 hours of thawing, while clotting factors are still viable, and is infused over a period of 15 to 30 minutes.
   c. Rh compatibility and ABO compatibility are required for the transfusion of plasma products.
d. Evaluation of an effective response is assessed by monitoring coagulation studies, particularly the prothrombin time and the partial thromboplastin time, and resolution of hypovolemia.

4. Cryoprecipitates
   a. Prepared from fresh-frozen plasma, cryoprecipitates can be stored for 1 year. Once thawed, the product must be used; 1 unit is administered over 15 to 30 minutes.
   b. Used to replace clotting factors, especially factor VIII and fibrinogen.
   c. Evaluation of an effective response is assessed by monitoring coagulation studies and fibrinogen levels.

5. Granulocytes
   a. May be used to treat a client with sepsis or a neutropenic client with an infection that is unresponsive to antibiotics.
   b. Evaluation of an effective response is assessed by monitoring the WBC and differential counts.

Document the necessary information about the blood transfusion in the client’s medical record (follow agency guidelines). Include the client’s tolerance and response to the transfusion and the effectiveness of the transfusion.

B. Types of blood donations
   1. Autologous
      a. A donation of the client’s own blood before a scheduled procedure is an autologous donation; it reduces the risk of disease transmission and potential transfusion complications.
      b. Autologous donation is not an option for a client with leukemia or bacteremia.
      c. A donation can be made every 3 days as long as the hemoglobin remains within
a safe range.
d. Donations should begin within 5 weeks of the transfusion date and end at least 3 days before the date of transfusion.

2. Blood salvage
   a. Blood salvage is an autologous donation that involves suctioning blood from body cavities, joint spaces, or other closed body sites.
   b. Blood may need to be “washed,” a special process that removes tissue debris before reinfusion.

3. Designated donor
   a. Designated donation occurs when recipients select their own compatible donors.
   b. Donation does not reduce the risk of contracting infections transmitted by the blood; however, recipients feel more comfortable identifying their donors.

C. Compatibility (Table 69-4)
   1. Client (the recipient) blood samples are drawn and labeled at the client’s bedside at the time the blood samples are drawn; the client is asked to state her or his name, which is compared with the name on the client’s identification band or bracelet.
   2. The recipient’s ABO type and Rh type are identified.
   3. An antibody screen is done to determine the presence of antibodies other than anti-A and anti-B.
   4. To determine compatibility, crossmatching is done, in which donor red blood cells are combined with the recipient’s serum and Coombs’ serum; the crossmatch is compatible if no RBC agglutination occurs.
   5. The universal RBC donor is O negative; the universal recipient is AB positive.
   6. Clients with Rh-positive blood can receive RBC transfusion from an Rh-negative donor if necessary; however, an Rh-negative client should not receive Rh-positive blood.

The donor’s blood and the recipient’s blood must be tested for
compatibility. If the blood is not compatible, a life-threatening transfusion reaction can occur.

D. Infusion pumps

1. Infusion pumps may be used to administer blood products if they are designed to function with opaque solutions; special IV tubing with a filter is used specifically for blood products to prevent hemolysis of red blood cells.
2. Always consult manufacturer guidelines for how to use the pump and compatibility for use with blood transfusions.
3. Special manual pressure cuffs designed specifically for blood product administration may be used to increase the flow rate, but it should not exceed 300 mm Hg.
4. Standard sphygmomanometer cuffs are not to be used to increase the flow rate because they do not exert uniform pressure against all parts of the bag.

E. Blood warmers

1. Blood warmers may be used to prevent hypothermia and adverse reactions when several units of blood are being administered.
2. Special warmers have been designed for this purpose, and only devices specifically approved for this use can be used.

If blood warming is necessary, use only warming devices specifically designed and approved for warming blood products. Do not warm blood products in a microwave oven or in hot water.

F. Precautions and nursing responsibilities (Box 69-4)

Check the client's identity (2 identifiers) with another licensed nurse before administering a blood product. Be sure to check the PHCP's prescription, that the client has an appropriate venous access site, that crossmatching procedures have been completed, that an informed consent has been obtained, and that the correct client is receiving the correct type of blood. Use barcode scanning systems per agency policy to ensure client safety.

G. Transfusion reactions (Box 69-5)

1. Description
   a. A transfusion reaction is an adverse reaction that happens as a result of receiving a blood transfusion.
b. Types of transfusion reactions include hemolytic, allergic, febrile or bacterial reactions (septicemia), or transfusion-associated graft-versus-host disease (GVHD).

2. Signs of an immediate transfusion reaction

   a. Chills and diaphoresis
   b. Muscle aches, back pain, or chest pain
   c. Rashes, hives, itching, and swelling
   d. Rapid, thready pulse
   e. Dyspnea, cough, or wheezing
   f. Pallor and cyanosis
   g. Apprehension
   h. Tingling and numbness
   i. Headache
   j. Nausea, vomiting, abdominal cramping, and diarrhea

3. Signs of a transfusion reaction in an unconscious client
   a. Weak pulse
   b. Fever
   c. Tachycardia or bradycardia
   d. Hypotension
   e. Visible hemoglobinuria
   f. Oliguria or anuria

4. Delayed transfusion reactions
   a. Reactions can occur days to years after a transfusion.
   b. Signs include fever, mild jaundice, and a decreased hematocrit level.

5. Interventions (see Priority Nursing Actions)

   ! Stay with the client for the first 15 minutes of the infusion of blood and monitor the client for signs and symptoms of a transfusion reaction; the first 15 minutes of the transfusion are the most critical, and the nurse must stay with the client. Vital signs are monitored every 30 minutes to 1 hour according to institutional protocol.

   ! Stop the transfusion immediately if a blood transfusion reaction is suspected.
# Priority Nursing Actions

## Transfusion Reaction
1. Stop the transfusion.
2. Change the intravenous (IV) tubing down to the IV site and keep the IV line open with normal saline.
3. Notify the primary health care provider (PHCP) and blood bank.
4. Stay with the client, observing signs and symptoms and monitoring vital signs as often as every 5 minutes.
5. Prepare to administer emergency medications as prescribed.
6. Obtain a urine specimen for laboratory studies (perform any other laboratory studies as prescribed).
7. Return blood bag, tubing, attached labels, and transfusion record to the blood bank.

## Reference

## H. Circulatory overload
1. Description: Caused by the infusion of blood at a rate too rapid for the client to tolerate
2. Assessment
   a. Cough, dyspnea, chest pain, and wheezing on auscultation of the lungs
   b. Headache
   c. Hypertension
   d. Tachycardia and a bounding pulse
   e. Distended neck veins
3. Interventions
   a. Slow the rate of infusion.
   b. Place the client in an upright position, with the feet in a dependent position.
   c. Notify the PHCP.
   d. Administer oxygen, diuretics, and morphine sulfate, as prescribed.
   e. Monitor for dysrhythmias.
   f. Phlebotomy also may be a method of prescribed treatment in a severe case.

## I. Septicemia
1. Description: Occurs with the transfusion of blood that is contaminated with microorganisms
2. Assessment
   a. Rapid onset of chills and a high fever
   b. Vomiting
   c. Diarrhea
   d. Hypotension
   e. Shock
3. Interventions
   a. Notify the PHCP.
   b. Obtain blood cultures and cultures of the blood bag.
   c. Administer oxygen, IV fluids, antibiotics, vasopressors, and corticosteroids as prescribed.

J. Iron overload
   1. Description: A delayed transfusion complication that occurs in clients who receive multiple blood transfusions, such as clients with anemia or thrombocytopenia
   2. Assessment
      a. Vomiting
      b. Diarrhea
      c. Hypotension
      d. Altered hematological values

3. Interventions
   a. Deferoxamine, administered intravenously or subcutaneously, removes accumulated iron via the kidneys.
   b. Urine turns red as iron is excreted after the administration of deferoxamine; treatment is discontinued when serum iron levels return to normal.

Contact the PHCP immediately if a transfusion reaction or a complication of blood administration arises.

K. Disease transmission
   1. The disease most commonly transmitted is hepatitis C, which is manifested by anorexia, nausea, vomiting, dark urine, and jaundice; the symptoms usually occur within 4 to 6 weeks after the transfusion.
   2. Other infectious agents and diseases transmitted by blood transfusion include hepatitis B virus, human immunodeficiency virus (HIV), human herpes virus type 6, Epstein-Barr virus, human T-cell leukemia, cytomegalovirus, and malaria.
   3. Donor screening has greatly reduced the risk of transmission of infectious agents; in addition, antibody testing of donors for HIV has greatly reduced the risk of transmission.
L. Hypocalcemia
1. Citrate in transfused blood binds with calcium and is excreted.
2. Assess serum calcium level before and after the transfusion.
3. Monitor for signs of hypocalcemia (hyperactive reflexes, paresthesias, tetany, muscle cramps, positive Trousseau’s sign, positive Chvostek’s sign).
4. Slow the transfusion and notify the PHCP if signs of hypocalcemia occur.

M. Hyperkalemia
1. Stored blood liberates potassium through hemolysis.
2. The older the blood, the greater the risk of hyperkalemia; therefore, clients at risk for hyperkalemia, such as those with renal insufficiency or renal failure, should receive fresh blood.
3. Assess the date on the blood and the serum potassium level before and after the transfusion.
4. Monitor the potassium level and for signs and symptoms of hyperkalemia (paresthesias, weakness, abdominal cramps, diarrhea, and dysrhythmias).
5. Slow the transfusion and notify the PHCP if signs of hyperkalemia occur.

N. Citrate toxicity
1. Citrate, the anticoagulant used in blood products, is metabolized by the liver.
2. Rapid administration of multiple units of stored blood may cause hypocalcemia and hypomagnesemia when citrate binds calcium and magnesium; this results in citrate toxicity, causing myocardial depression and coagulopathy.
3. Those most at risk include individuals with liver dysfunction or neonates with immature liver function.
4. Treatment includes slowing or stopping the transfusion to allow the citrate to be metabolized; hypocalcemia and hypomagnesemia are also treated with replacement therapy.

IV. Tube Care
A. Nasogastric (NG) tubes
1. These are tubes used to intubate the stomach.
2. The tube is inserted from the nose to the stomach.
B. Purpose
1. To decompress the stomach by removing fluids or gas
to promote abdominal comfort
2. To allow surgical anastomoses to heal without distention
3. To decrease the risk of aspiration
4. To administer medications to clients who are unable to swallow
5. To provide nutrition by acting as a temporary feeding tube
6. To irrigate the stomach and remove toxic substances, such as in poisoning

C. Types of tubes
1. Levin tube (Fig. 69-8)
   a. Single-lumen nasogastric tube
   b. Used to remove gastric contents via intermittent suction or to provide tube feedings
2. Salem sump tube: A Salem sump is a double-lumen nasogastric tube with an air vent (pigtail) used for decompression with intermittent continuous suction (see Fig. 69-8).

The air vent on a Salem sump tube is not to be clamped and is to be kept above the level of the stomach. If leakage occurs through the air vent, instill 30 mL of air into the air vent and irrigate the main lumen with normal saline (NS).

D. Intubation procedures (Box 69-6)

E. Irrigation
1. Assess placement before irrigating (see Box 69-6).
2. Perform irrigation every 4 hours to assess and maintain the patency of the tube.
3. Gently instill 30 to 50 mL of water or NS (depending on agency policy) with an irrigation syringe.
4. Pull back on the syringe plunger to withdraw the fluid to check patency; repeat if the tube flow is sluggish.

F. Removal of a nasogastric tube: Ask the client to take a deep breath and hold it; remove the tube slowly and evenly over the course of 3 to 6 seconds (coil the tube around the hand while removing it).

G. Gastrointestinal tube feedings
1. Types of tubes and anatomical placement
   a. Nasogastric: Nose to stomach
   b. Nasoduodenal-nasojejunal: Nose to duodenum or jejunum
c. Gastrostomy: Stomach
d. Jejunostomy: Jejunum

2. Types of administration
   a. Bolus: A bolus resembles normal meal feeding patterns; formula is administrated over a 30- to 60-minute period every 3 to 6 hours; the amount of formula and frequency can be recommended by the dietitian and is prescribed by the PHCP.
   b. Continuous: Feeding is administered continually for 24 hours; an infusion feeding pump regulates the flow.
   c. Cyclical: Feeding is administered in the daytime or nighttime for approximately 8 to 16 hours (feedings at night allow for more freedom during the day).
   d. An infusion feeding pump regulates the flow.

3. Administration of feedings
   a. Check the PHCP’s prescription and agency policy regarding residual amounts; usually, if the residual is less than 100 mL, feeding is administered; large-volume aspirates indicate delayed gastric emptying and place the client at risk for aspiration.
   b. Assess bowel sounds; hold the feeding and notify the PHCP if bowel sounds are absent.
   c. Position the client in a high-Fowler’s position; if comatose, place in high-Fowler’s and on the right side.
   d. Assess tube placement by aspirating gastric contents and measuring the pH (should be 3.5 or lower) or per agency procedure.
   e. Aspirate all stomach contents (residual), measure the amount, and return the contents to the stomach to prevent electrolyte imbalances (unless the color or characteristics of the residual is abnormal or the amount is greater than 250 mL).
   f. Warm the feeding to room temperature to prevent diarrhea and cramps.
g. Use an infusion feeding pump for continuous or cyclic feedings.

h. For bolus feeding, maintain the client in a high-Fowler’s position for 30 minutes after the feeding. Use an infusion pump or allow the feeding to infuse via gravity. Do not plunge the feeding into the stomach.

i. For a continuous feeding, keep the client in a semi-Fowler’s position at all times.

4. Precautions

Always assess the placement of a gastrointestinal tube before instilling feeding solutions, medications, or any other solution. If the tube is incorrectly placed, the client is at risk for aspiration.

a. Change the feeding container and tubing every 24 hours or per agency policy.

b. Do not hang more solution than is required for a 4-hour period; this prevents bacterial growth.

c. Check the expiration date on the formula before administering.

d. Shake the formula well before pouring it into the container (feeding bag). Some feedings require the use of a bag in which formula is added, or require the use of bottles that feeding tubing can be attached to directly. The tubing sometimes has a Y-site connection so a regular flush can be programmed using the pump rather than using a piston syringe.

e. Always assess bowel sounds; do not administer any feedings if bowel sounds are absent.

f. Administer the feeding at the prescribed rate or via gravity flow (intermittent bolus feedings) with a 50- to 60-mL syringe with the plunger removed.

g. Gently flush with 30 to 50 mL of water or NS (depending on agency policy) using the irrigation syringe after the feeding.
5. Complications of feedings include aspiration, diarrhea, vomiting, a clogged tube.

6. Aspiration
   a. Verify tube placement.
   b. Do not administer the feeding if residual is more than 100 mL (check PHCP’s prescription and agency policy).
   c. Keep the head of the bed elevated.
   d. If aspiration occurs, suction as needed, assess respiratory rate, auscultate lung sounds, monitor temperature for aspiration pneumonia, and prepare to obtain a chest radiograph.

7. Diarrhea
   a. Assess the client for lactose intolerance.
   b. Use fiber-containing feedings.
   c. Administer feeding slowly and at room temperature.

8. Vomiting
   a. Administer feedings slowly and, for bolus feedings, make feeding last for at least 30 minutes.
   b. Measure abdominal girth.
   c. Do not allow the feeding bag to empty.
   d. Do not allow air to enter the tubing.
   e. Administer the feeding at room temperature.
   f. Elevate the head of the bed.
   g. Administer antiemetics as prescribed.

9. Clogged tube
   a. Use liquid forms of medication, if possible.
   b. Flush the tube with 30 to 50 mL of water or NS (depending on agency policy) before and after medication administration and before and after bolus feeding.
   c. Flush with water every 4 hours for continuous feeding.

   If the client vomits, stop the tube feeding and place the client in a side-lying position; suction the client as needed.
H. Administration of medications (see Priority Nursing Actions)

**Priority Nursing Actions**

Administering Medications via a Nasogastric, Gastrostomy, or Jejunostomy Tube

1. Check the primary health care provider’s (PHCP’s) prescription.
2. Prepare the medication for administration.
3. Ensure that the medication prescribed can be crushed or is a capsule that can be opened; use elixir forms of medications if available.
4. Dissolve crushed medication or capsule contents in 15 to 30 mL of water.
5. Verify the client’s identity (2 identifiers) and explain the procedure to the client.
6. Don gloves; check tube placement and residual contents before instilling the medication; check for bowel sounds.
7. Flush with 30 to 50 mL of water or normal saline (NS), depending on agency policy.
8. Pinch off tubing and attach an irrigation syringe to the nasogastric tube and pour the medication into the syringe. Release the pinch on the tubing immediately and allow medication to infuse via gravity.
9. Flush with 30 to 50 mL of water or normal saline (NS), depending on agency policy.
10. Clamp the tube for 30 to 60 minutes, depending on medication and agency policy.
11. Document the administration of the medication and any other appropriate information.

Reference

I. Intestinal tubes

1. Description

   a. The intestinal tube is passed nasally into the small intestine.
   b. It may be used to decompress the bowel or to remove accumulated intestinal secretions when other interventions to decompress the bowel are not effective.
   c. The tube enters the small intestine through the pyloric sphincter because of the weight of a small bag containing tungsten at the end.
   d. Types of tubes include the Cantor tube (single lumen) and the Miller-Abbott tube (double lumen) (see Fig. 69-8).

2. Interventions

   a. Assess the PHCP’s prescriptions and agency policy for advancement and
removal of the tube and tungsten.

b. Position the client on the right side to facilitate passage of the weighted bag in the tube through the pylorus of the stomach and into the small intestine.

c. Assess the abdomen during the procedure by monitoring drainage from the tube and the abdominal girth.

d. Do not secure the tube to the face with tape until it has reached final placement (may take several hours) in the intestines.

e. If the tube becomes blocked, notify the PHCP.

f. To remove the tube, the tungsten is removed from the balloon portion of the tube with a syringe; the tube is removed gradually (6 inches [15 cm] every hour) as prescribed by the PHCP.

J. Esophageal and gastric tubes

1. Description

a. May be used to apply pressure against bleeding esophageal veins to control the bleeding when other interventions are not effective or they are contraindicated.

b. Not used if the client has ulceration or necrosis of the esophagus or has had previous esophageal surgery because of the risk of rupture.

2. Sengstaken-Blakemore tube and Minnesota tube (see Fig. 69-8)

a. The Sengstaken-Blakemore tube, used only occasionally, is a triple-lumen gastric tube with an inflatable esophageal balloon (compresses esophageal varices), an inflatable gastric balloon (applies pressure at the cardioesophageal junction), and a gastric aspiration lumen. A nasogastric tube also is inserted in the opposite naris to collect secretions that accumulate above the esophageal balloon.

b. More commonly used is the Minnesota tube, which is a modified Sengstaken-Blakemore tube with an additional
lumen (a 4-lumen gastric tube) for
aspirating esophagopharyngeal
secretions.
c. A radiograph of the upper abdomen
and chest confirms placement.

3. Interventions

a. Check patency and integrity of all
   balloons before insertion.
b. Label each lumen.
c. Place the client in the upright or
   Fowler’s position for insertion.
d. Immediately after insertion, prepare for
   radiography to verify placement.
e. Maintain head elevation once the tube
   is in place.
f. Double-clamp the balloon ports to
   prevent air leaks.
g. Keep scissors at the bedside at
   all times; monitor for respiratory
   distress, and if it occurs, cut the tubes
   to deflate the balloons.
h. To prevent ulceration or necrosis of the
   esophagus, release esophageal
   pressure at intervals as prescribed and
   per agency policy.
i. Monitor for increased bloody drainage,
   which may indicate persistent bleeding
   and rupture of the varices.
j. Monitor for signs of esophageal rupture,
   which include a drop in blood
   pressure, increased heart rate, and
   back and upper abdominal pain.
   Esophageal rupture is an emergency,
   and signs of esophageal rupture must
   be reported to the PHCP immediately.

K. Lavage tubes
1. Used to remove toxic substances from the stomach
2. Types of tubes
   a. Lavacuator: The Lavacuator is an
      orogastric tube with a large suction
      lumen and a smaller lavage–vent
      lumen that provides continuous
      suction; irrigation solution enters the
      lavage lumen while stomach contents
      are removed through the suction
lumen (see Fig. 69-9).

b. Ewald tube: A single-lumen large tube used for rapid 1-time irrigation and evacuation

L. Urinary and renal tubes

1. Types of urinary catheters
   a. Single lumen: Usually used for straight catheterization to empty the client’s bladder, obtain sterile urine specimens, or check the residual amount of urine after the client voids
   b. Double lumen: Used when an indwelling catheter is needed for continuous bladder drainage; one lumen is for drainage and the other is for balloon inflation.
   c. Triple lumen: Used when bladder irrigation and drainage is necessary; 1 lumen is for instilling the bladder irrigant solution, 1 lumen is for continuous bladder drainage, and 1 lumen is for balloon inflation.
   d. Strict aseptic technique is necessary for insertion and care of the catheter.

2. Routine urinary catheter care
   a. Use gloves and wash the perineal area with warm soapy water.
   b. With the nondominant hand, pull back the labia or foreskin to expose the meatus (in the adult male, return the foreskin to its normal position).
   c. Cleanse along the catheter with soap and water.
   d. Anchor the catheter to the thigh.
   e. Maintain the catheter bag below the level of the bladder.

3. Ureteral and nephrostomy tubes (Fig. 69-9)
   a. Never clamp the tube.
   b. Maintain patency.
   c. Irrigate only if prescribed by the PHCP, using strict aseptic technique; a maximum of 5 mL of sterile NS is instilled slowly and gently.
   d. If patency cannot be established with the prescribed irrigation, notify the PHCP immediately.

4. Catheter insertion and removal (Box 69-7)
If the client has a ureteral or nephrostomy tube, monitor output closely; urine output of less than 30 mL/hr or lack of output for more than 15 minutes should be reported to the PHCP immediately.

M. Respiratory system tubes

1. Endotracheal tubes (Fig. 69-10)
   a. The endotracheal tube is used to maintain a patent airway.
   b. Endotracheal tubes are indicated when the client needs mechanical ventilation.
   c. If the client requires an artificial airway for longer than 10 to 14 days, a tracheostomy may be created to avoid mucosal and vocal cord damage that can be caused by the endotracheal tube.
   d. The cuff (located at the distal end of the tube), when inflated, produces a seal between the trachea and the cuff to prevent aspiration and ensure delivery of a set tidal volume when mechanical ventilation is used; an inflated cuff also prevents air from passing to the vocal cords, nose, or mouth.
   e. The pilot balloon permits air to be inserted into the cuff, prevents air from escaping, and is used as a guideline for determining the presence or absence of air in the cuff.
   f. The universal adapter enables attachment of the tube to mechanical ventilation tubing or other types of oxygen delivery systems.
   g. Types of tubes: orotracheal and nasotracheal

2. Orotracheal tubes
   a. Inserted through the mouth; allows use of a larger diameter tube and reduces the work of breathing
   b. Indicated when the client has a nasal obstruction or a predisposition to epistaxis
   c. Uncomfortable and can be manipulated by the tongue, causing airway obstruction; an oral airway may be needed to keep the client from biting on the tube.

3. Nasotracheal tubes
a. Inserted through a nostril; this smaller tube increases resistance and the client’s work of breathing.
b. Its use is avoided in clients with bleeding disorders.
c. It is more comfortable for the client, and the client is unable to manipulate the tube with the tongue.

4. Interventions

a. Placement is confirmed by chest x-ray film (correct placement is 1 to 2 cm above the carina).
b. Assess placement by auscultating both sides of the chest while manually ventilating with a resuscitation (Ambu) bag (if breath sounds and chest wall movement are absent in the left side, the tube may be in the right main stem bronchus).
c. Perform auscultation over the stomach to rule out esophageal intubation.
d. If the tube is in the stomach, louder breath sounds will be heard over the stomach than over the chest, and abdominal distention will be present.
e. Secure the tube with adhesive tape immediately after intubation.
f. Monitor the position of the tube at the lip or nose.
g. Monitor skin and mucous membranes.
h. Suction the tube only when needed.
i. The oral tube needs to be moved to the opposite side of the mouth daily to prevent pressure and necrosis of the lip and mouth area, prevent nerve damage, and facilitate inspection and cleaning of the mouth; moving the tube to the opposite side of the mouth should be done by 2 health care providers.
j. Prevent dislodgment and pulling or tugging on the tube; suction, coughing, and speaking attempts by the client place extra stress on the tube and can cause dislodgment.
k. Assess the pilot balloon to ensure that the cuff is inflated; maintain cuff
inflation, which creates a seal and allows complete mechanical control of respiration.

1. Monitor cuff pressures at least every 8 hours per agency procedure to ensure that they do not exceed 20 mm Hg (an aneroid pressure manometer is used to measure cuff pressures); minimal leak and occlusive techniques are used for cuff inflation to check cuff pressures.

A resuscitation (Ambu) bag needs to be kept at the bedside of a client with an endotracheal tube or a tracheostomy tube at all times.

5. Minimal leak technique
   a. This is used for cuff inflation and checking cuff pressures for cuffs without pressure relief valves.
   b. Inflate the cuff until a seal is established; no harsh sound should be heard through a stethoscope placed over the trachea when the client breathes in, but a slight air leak on peak inspiration is present and can be heard.
   c. The client cannot make verbal sounds, and no air is felt coming out of the client’s mouth.

6. Occlusive technique
   a. This is used for cuff inflation and checking cuff pressures for cuffs with pressure relief valves.
   b. Provides an adequate seal in the trachea at the lowest possible cuff pressure.
   c. Uses same procedure as minimal leak technique, without an air leak.

7. Extubation
   a. Hyperoxygenate the client and suction the endotracheal tube and the oral cavity.
   b. Place the client in a semi-Fowler’s position.
   c. Deflate the cuff; have the client inhale and, at peak inspiration, remove the tube, suctioning the airway through
the tube while pulling it out.

d. After removal, instruct the client to cough and deep-breathe to assist in removing accumulated secretions in the throat.

e. Apply oxygen therapy, as prescribed.

f. Monitor for respiratory difficulty; contact the PHCP if respiratory difficulty occurs.

g. Inform the client that hoarseness or a sore throat is normal and that the client should limit talking if it occurs.

N. Tracheostomy

1. A tracheostomy is an opening made surgically directly into the trachea to establish an airway; a tracheostomy tube is inserted into the opening and the tube attaches to the mechanical ventilator or another type of oxygen delivery device (Fig. 69-11).

2. Types: The tracheostomy can be temporary or permanent (Box 69-8).

3. Interventions

   a. Assess respirations and for bilateral breath sounds.

   b. Monitor arterial blood gases and pulse oximetry.

   c. Encourage coughing and deep breathing.

   d. Maintain a semi-Fowler’s to high-Fowler’s position.

   e. Monitor for bleeding, difficulty with breathing, absence of breath sounds, and crepitus (subcutaneous emphysema), which are indications of hemorrhage or pneumothorax.

   f. Provide respiratory treatments as prescribed.

   g. Suction fluids as needed; hyperoxygenate the client before suctioning (see Priority Nursing Actions).

   h. If the client is allowed to eat, sit the client up for meals and ensure that the cuff is inflated (if the tube is not capped) for meals and for 1 hour after meals to prevent aspiration.

   i. Monitor cuff pressures as prescribed.

   j. Assess the stoma and secretions for
blood or purulent drainage.
k. Follow the PHCP’s prescriptions and agency policy for cleaning the tracheostomy site and inner cannula (many inner cannulas are disposable); usually, half-strength hydrogen peroxide is used.
l. Administer humidified oxygen as prescribed, because the normal humidification process is bypassed in a client with a tracheostomy.
m. Obtain assistance in changing tracheostomy ties; after placing the new ties, cut and remove the old ties holding the tracheostomy in place (some securing devices are soft and made with Velcro to hold the tube in place).
n. Keep a resuscitation (Ambu) bag, obturator, clamps, and spare tracheostomy tube of the same size at the bedside.

4. Complications of a tracheostomy (Table 69-5)

Never insert a plug (cap) into a tracheostomy tube until the cuff is deflated and the inner cannula is removed; prior insertion prevents airflow to the client.

Priority Nursing Actions

Tracheal Suctioning
1. Assess the client and explain the procedure.
2. Assist the client to an upright position.
3. Perform hand hygiene and don personal protective equipment.
4. Prepare suctioning equipment and turn on the suction.
5. Hyperoxygenate the client.
6. Insert the catheter without suction applied.
7. Once inserted, apply suction intermittently while rotating and withdrawing the catheter.
8. Hyperoxygenate the client.
9. Listen to breath sounds and reassess oxygen saturation.

Reference
O. Chest Tube Drainage System

1. The chest tube drainage system returns negative pressure to the intrapleural space.
2. The system is used to remove abnormal accumulations of air and fluid from the pleural space (Fig. 69-12).
3. Drainage collection chamber (Fig. 69-13)
   a. The drainage collection chamber is located where the chest tube from the client connects to the system.
   b. Drainage from the tube drains into and collects in a series of calibrated columns in this chamber.
4. Water seal chamber (see Fig. 69-13)
   a. The tip of the tube is underwater, allowing fluid and air to drain from the pleural space and preventing air from entering the pleural space.
   b. Water oscillates (moves up as the client inhales and moves down as the client exhales).
   c. Excessive bubbling indicates an air leak in the chest tube system.
5. Suction control chamber (see Fig. 69-13)
   a. The suction control chamber provides the suction, which can be controlled to provide negative pressure to the chest.
   b. This chamber is filled with various levels of water to achieve the desired level of suction; without this control, lung tissue could be sucked into the chest tube.
   c. Gentle bubbling in this chamber indicates that there is suction and does not indicate that air is escaping from the pleural space.
6. Dry suction system (see Fig. 69-13)
   a. This is another type of chest drainage system. Because this is a dry suction system, absence of bubbling is noted in the suction control chamber.
   b. A knob on the collection device is used to set the prescribed amount of suction; then the wall suction source dial is turned until a small orange floater valve appears in the window on the device (when the orange floater valve is in the window, the correct
amount of suction is applied).

7. Portable chest drainage system: Small and portable chest drainage systems are also available and are dry systems that use a control flutter valve to prevent the backflow of air into the client’s lung. Principles of gravity and pressure, and the nursing care involved, are the same for all types of systems, and these systems allow greater ambulation and allow the client to go home with the chest tubes in place.

8. Collection chamber: Interventions
   a. Monitor drainage; notify the PHCP if drainage is more than 70 to 100 mL/hr or if drainage becomes bright red or increases suddenly.
   b. Mark the chest tube drainage in the collection chamber at 1- to 4-hour intervals, using a piece of tape.

9. Water seal chamber: Interventions
   a. Monitor for fluctuation of the fluid level in the water seal chamber.
   b. Fluctuation in the water seal chamber stops if the tube is obstructed, if a dependent loop exists, if the suction is not working properly, or if the lung has re-expanded.
   c. If the client has a known pneumothorax, intermittent bubbling in the water seal chamber is expected as air is drained from the chest, but continuous bubbling indicates an air leak in the system.
   d. Notify the PHCP if there is continuous bubbling in the water seal chamber.

10. Suction control chamber: Interventions: Gentle (not vigorous) bubbling should be noted in the suction control chamber of a wet suction system.

11. Additional interventions
   a. An occlusive sterile dressing is maintained at the insertion site.
   b. A chest radiograph assesses the position of the tube and determines whether the lung has re-expanded.
   c. Assess respiratory status and auscultate lung sounds. Assess chest tube dressing for drainage and palpate surrounding tissue for crepitus.
   d. Monitor for signs of extended
pneumothorax or hemothorax.
e. Keep the drainage system below the level of the chest and the tubes free of kinks, dependent loops, or other obstructions.
f. Ensure that all connections are secure.
g. Encourage coughing and deep breathing.
h. Change the client’s position frequently to promote drainage and ventilation.
i. Do not strip or milk a chest tube unless specifically directed to do so by the PHCP and if agency policy allows it.
j. Keep a clamp (may be needed if the system needs to be changed) and a sterile occlusive dressing at the bedside at all times.
k. Never clamp a chest tube without a written prescription from the PHCP; also, determine agency policy for clamping a chest tube.
l. If the drainage system cracks or breaks, insert the chest tube into a bottle of sterile water, remove the cracked or broken system, and replace it with a new system.
m. Depending on the PHCP’s preference, when the chest tube is removed, the client may be asked to take a deep breath and hold it, and the tube is removed. Or, the client may be asked to take a deep breath, exhale, and bear down (Valsalva maneuver). A dry sterile dressing, petroleum gauze dressing, or Telfa dressing (depending on the PHCP’s preference) is taped in place after removal of the chest tube.

If the chest tube is pulled out of the chest accidentally, pinch the skin opening together, apply an occlusive sterile dressing, cover the dressing with overlapping pieces of 2-inch (5-cm) tape, and call the PHCP immediately.

V. Complex Integumentary Problems
   A. Burn injuries (see Priority Nursing Actions)
Priority Nursing Actions

Burn Injury: Care in the Emergency Department

1. Assess for airway patency.
2. Administer oxygen as prescribed.
3. Obtain vital signs.
4. Initiate an intravenous (IV) line and begin fluid replacement as prescribed.
5. Elevate the extremities if no fractures are obvious.
6. Keep the client warm and place the client on NPO (nothing by mouth) status.

Reference

1. Description: Cell destruction of the layers of the skin caused by heat, friction, electricity, radiation, or chemicals.
2. Small burns: The response of the body to injury is localized to the injured area.
3. Large or extensive burns:
   a. Major or extensive burns consist of 25% or more of the total body surface area for an adult and 10% or more of the total body surface for a child.
   b. The response of the body to the injury is systemic.
   c. The burn affects all major systems of the body.
   d. Electrical burns often have surface injury that is small, but internal injuries may be extensive.

4. Estimating the extent of injury (Fig. 69-14)

B. Burn depth

1. **Superficial-thickness burn**
   a. Involves injury to the epidermis; the blood supply to the dermis is still intact.
   b. Mild to severe erythema (pink to red) is present, but no blisters.
   c. Skin blanches with pressure.
   d. Burn is painful, with tingling sensation, and the pain is eased by cooling.
   e. Discomfort lasts about 48 hours; healing occurs in about 3 to 6 days.
   f. No scarring occurs and skin grafts are not required.
2. **Superficial partial-thickness burn** (Fig. 69-15)
   a. Involves injury deeper into the dermis; the blood supply is reduced.
   b. Large blisters may cover an extensive area.
   c. Edema is present.
   d. Mottled pink to red base and broken epidermis, with a wet, shiny, and weeping surface, are characteristic.
   e. Burn is painful and sensitive to cold air.
   f. Heals in 10 to 21 days with no scarring, but some minor pigment changes may occur.
   g. Grafts may be used if the healing process is prolonged.

3. **Deep partial-thickness burn** (Fig. 69-16)
   a. Extends deeper into the skin dermis.
   b. Blister formation usually does not occur because the dead tissue layer is thick and sticks to underlying viable dermis.
   c. Wound surface is red and dry with white areas in deeper parts.
   d. May or may not blanch, and edema is moderate.
   e. Can convert to full-thickness burn if tissue damage increases with infection, hypoxia, or ischemia.
   f. Generally heals in 3 to 6 weeks, but scar formation results and skin grafting may be necessary.

4. **Full-thickness burn** (Fig. 69-17)
   a. Involves injury and destruction of the epidermis and the dermis; the wound will not heal by re-epithelialization, and grafting may be required.
   b. Appears as a dry, hard, leathery eschar (burn crust or dead tissue must slough off or be removed from the wound before healing can occur).
   c. Appears waxy white, deep red, yellow, brown, or black.
   d. Injured surface appears dry.
   e. Edema is present under the eschar.
   f. Sensation is reduced or absent because of nerve ending destruction.
   g. Healing may take weeks to months and depends on establishing an adequate blood supply.
h. Burn requires removal of eschar and split- or full-thickness skin grafting.
i. Scarring and wound contractures are likely to develop.

5. Deep full-thickness burn (Fig. 69-18)
a. Injury extends beyond the skin into underlying fascia and tissues, and muscle, bone, and tendons are damaged.
b. Injured area appears black and sensation is completely absent.
c. Eschar is hard and inelastic.
d. There is lack of pain because nerve endings have been destroyed.
e. Healing takes months and grafts are required.

C. Burn location
1. Burns of the head, neck, and chest are associated with pulmonary complications.
2. Burns of the face are associated with corneal abrasion.
3. Burns of the ear are associated with auricular chondritis.
4. Hands and joints require intensive therapy to prevent disability.
5. The perineal area is prone to autocontamination by urine and feces.
6. Circumferential burns of the extremities can produce a tourniquet-like effect and lead to vascular compromise (compartment syndrome).
7. Circumferential thorax burns lead to inadequate chest wall expansion and pulmonary insufficiency.

D. Age and general health
1. Mortality rates are higher for children younger than 4 years of age, particularly for children from birth to 1 year of age, and for clients older than 65 years.
2. Debilitating disorders, such as cardiac, respiratory, endocrine, and renal disorders, negatively influence the client’s response to injury and treatment.
3. Mortality rate is higher when the client has a pre-existing disorder at the time of the burn injury.

E. Inhalation injuries
1. Smoke inhalation injury
   a. Respiratory injury that occurs when the victim inhales products of combustion during a fire.
The airway is a priority concern in an inhalation injury.

b. Assessment (Box 69-9)

2. Carbon monoxide poisoning
   a. Carbon monoxide is a colorless, odorless, and tasteless gas that has an affinity for hemoglobin 200 times greater than that of oxygen.
   b. Oxygen molecules are displaced and carbon monoxide reversibly binds to hemoglobin to form carboxyhemoglobin.
   c. Tissue hypoxia occurs.
   d. Assessment (Table 69-6)

3. Direct thermal heat injury
   a. Thermal heat injury can occur to the lower airways by the inhalation of steam or explosive gases or the aspiration of scalding liquids.
   b. Injury can occur to the upper airways, which appear erythematous and edematous, with mucosal blisters and ulcerations.
   c. Mucosal edema can lead to upper airway obstruction, especially during the first 24 to 48 hours.
   d. All clients with head or neck burns should be monitored closely for the development of airway obstruction and are considered immediately for endotracheal intubation if obstruction occurs.
   e. Assessment: findings include erythema and edema of the upper airways and mucosal blisters and ulcerations

F. Pathophysiology of burns
   1. Following a burn, vasoactive substances are released from the injured tissue, and these substances cause an increase in capillary permeability, allowing the plasma to seep into the surrounding tissues.
   2. The direct injury to the vessels increases capillary permeability (capillary permeability decreases 18 to 26 hours after the burn but does not normalize until 2 to 3 weeks following injury).
3. Extensive burns result in generalized body edema and a decrease in circulating intravascular blood volume.

4. The fluid losses result in a decrease in organ perfusion.

5. The heart rate increases, cardiac output decreases, and blood pressure drops.

6. Initially, hyponatremia and hyperkalemia occur.

7. The hematocrit level increases as a result of plasma loss; this initial increase falls to below normal by the third to fourth day after the burn as a result of red blood cell damage and loss at the time of injury.

8. Initially, the body shunts blood from the kidneys, causing oliguria; then the body begins to reabsorb fluid, and diuresis of the excess fluid occurs over the next days to weeks.

9. Blood flow to the gastrointestinal tract is diminished, leading to intestinal ileus and gastrointestinal dysfunction.

10. Immune system function is depressed, resulting in immunosuppression and thus increasing the risk of infection and sepsis.

11. Pulmonary hypertension can develop, resulting in a decrease in the arterial oxygen tension level and a decrease in lung compliance.

12. Evaporative fluid losses through the burn wound are greater than normal, and the losses continue until complete wound closure occurs.

13. If the intravascular space is not replenished with intravenously administered fluids, hypovolemic shock and ultimately death occur.

G. Management of the burn injury: Resuscitation/emergent phase (Table 69-7)

1. Prehospital care
   a. Begins at the scene of the accident and ends when emergency care is obtained
   b. Remove the victim from the source of the burn.
   c. Assess the ABCs—airway, breathing, and circulation.
   d. Assess for associated trauma, including inhalation injury.
   e. Conserve body heat.
   f. Cover burns with sterile or clean cloths.
g. Remove constricting jewelry and clothing.
h. Insert IV access.
i. Transport to the emergency department.

2. Emergency department care is a continuation of care administered at the scene of the injury.

3. Major burns

   a. Evaluate the degree and extent of the burn and treat life-threatening conditions.
   b. Ensure a patent airway and administer 100% oxygen as prescribed.
   c. Monitor for respiratory distress and assess the need for intubation.
   d. Assess the oropharynx for blisters and erythema; assess vocal quality and for singed nasal hairs and auscultate lung sounds.
   e. Monitor arterial blood gases and carboxyhemoglobin levels.
   f. For an inhalation injury, administer 100% oxygen via a tight-fitting nonrebreather face mask as prescribed until the carboxyhemoglobin level falls below 15%.
   g. Initiate peripheral IV access to nonburned skin proximal to any extremity burn, or prepare for the insertion of a central venous line as prescribed.
   h. Assess for hypovolemia and prepare to administer fluids intravenously to maintain fluid balance.
   i. Monitor vital signs closely.
   j. Insert a Foley catheter as prescribed, and manage fluid resuscitation with a goal to maintain urine output at 30 to 50 mL/hr.
   k. Maintain NPO (nothing by mouth) status.
   l. Insert a nasogastric tube as prescribed to remove gastric secretions and prevent aspiration.
   m. Administer tetanus prophylaxis as prescribed.
   n. Administer pain medication, as prescribed, by the IV route.
   o. Administer wound care and prepare
the client for an escharotomy or fasciotomy as prescribed.

4. Minor burns
   a. Administer pain medication as prescribed.
   b. Instruct the client in the use of oral analgesics as prescribed.
   c. Administer tetanus prophylaxis as prescribed.
   d. Administer wound care as prescribed, which may include cleansing, debriding loose tissue, and removing any damaging agents, followed by the application of topical antimicrobial cream and a sterile dressing.
   e. Instruct the client in follow-up care, including active range-of-motion exercises and wound care treatments.

H. Management of the burn injury: Resuscitative phase (see Table 69-7)

1. Fluid resuscitation (Table 69-8)
   a. The amount of fluid administered depends on how much IV fluid per hour is required to maintain a urinary output of 30 to 50 mL/hr.
   b. Successful fluid resuscitation is evaluated by stable vital signs, an adequate urine output, palpable peripheral pulses, and intact level of consciousness and thought processes.
   c. IV fluid replacement may be titrated (adjusted) on the basis of urinary output plus serum electrolyte levels to meet the perfusion needs of the client with burns.
   d. If the hemoglobin and hematocrit levels decrease or if the urinary output exceeds 50 mL/hr, the rate of IV fluid administration may be decreased.

> Urinary output is the most reliable and most sensitive noninvasive assessment parameter for cardiac output and tissue perfusion.

2. Interventions
a. Monitor for tracheal or laryngeal edema and administer respiratory treatments as prescribed; intubation and mechanical ventilation are instituted with respiratory burns before complications develop, if needed.
b. Monitor pulse oximetry and prepare for arterial blood gases and carboxyhemoglobin levels if inhalation injury is suspected.
c. Elevate the head of the bed to 30 degrees or more for burns of the face and head.
d. Monitor for fluid overload and pulmonary edema.
e. Initiate electrocardiographic (ECG) monitoring.
f. Monitor temperature and assess for infection.

  g. Initiate protective isolation techniques; maintain strict hand washing; use sterile sheets and linens when caring for the client; and use gloves, cap, masks, shoe covers, scrub clothes, and plastic aprons.

h. Clip body hair around wound margins.
i. Monitor daily weights, expecting a weight gain of 6 to 9 kilograms (15 to 20 pounds) in the first 72 hours.
j. Monitor gastric output and pH levels and for gastric discomfort and bleeding, indicating a stress ulcer.
k. Administer antacids, H2 receptor antagonists, and antiulcer medications as prescribed to prevent a stress ulcer.
l. Auscultate bowel sounds for ileus and monitor for abdominal distention and gastrointestinal dysfunction.
m. Monitor stools for occult blood.
n. Obtain urine specimen for myoglobin and hemoglobin levels.
o. Monitor IV fluids and hourly intake and output to determine the adequacy of fluid replacement therapy; notify the PHCP if urine output is less than 30 or greater than 50 mL/hr. Monitor serum laboratory results, including electrolytes and complete blood count.
p. Elevate circumferential burns of the extremities on pillows above the level of the heart to reduce dependent edema if no obvious fractures are present; diuretics increase the risk of hypovolemia and are generally avoided as a means of decreasing edema.

q. Monitor pulses and capillary refill of the affected extremities and assess perfusion of the distal extremity with a circumferential burn.

r. Prepare to obtain chest x-rays and other radiographs to rule out fractures or associated trauma.

s. Keep the room temperature warm.

t. Place the client on an air-fluidized bed or other special mattress and use a bed cradle to keep sheets off the client’s skin.

3. Pain management

a. Administer opioid analgesics as prescribed by the IV route.

b. Avoid administering medication by the oral route because of the possibility of gastrointestinal dysfunction.

c. Medicate the client as prescribed and before painful procedures.

Avoid the intramuscular or subcutaneous medication route for medication administration, because absorption through the soft tissue is unreliable when hypovolemia and large fluid shifts occur.

4. Nutrition

a. Proper nutrition is essential to promote wound healing and prevent infection.

b. The basal metabolic rate is 40 to 100 times higher than normal with a burn injury.

c. Maintain NPO status until bowel sounds are heard, and then advance to clear liquids as prescribed.

d. Dietary consultation may be prescribed. Nutrition may be provided via enteral tube feeding or parenteral nutrition through a central line.
e. Provide a diet high in protein, carbohydrates, fats, and vitamins, with major burns requiring more than 5000 calories daily.

f. Monitor calorie intake and daily weights.

I. Management of the burn injury: Acute phase (see Table 69-7)

1. Continue with protective isolation techniques.
2. Provide wound care as prescribed and prepare for wound closure.
3. Provide pain management.
4. Provide adequate nutrition as prescribed.
5. Prepare the client for rehabilitation.

J. Circulatory compromise treatments

1. Escharotomy
   a. A lengthwise incision is made through the burn eschar to relieve constriction and pressure and to improve circulation.
   b. Escharotomy is performed for circulatory compromise caused by circumferential burns.
   c. Escharotomy can be performed at the bedside without anesthesia, because nerve endings have been destroyed by the burn injury.
   d. Escharotomy may be necessary on the thorax to improve ventilation.
   e. Following the escharotomy, assess pulses, color, movement, and sensation of affected extremity and control any bleeding with pressure.
   f. Pack the incision gently with fine mesh gauze as prescribed after escharotomy.
   g. Apply topical antimicrobial agents to the area as prescribed.

2. Fasciotomy
   a. An incision is made extending through the subcutaneous tissue and fascia.
   b. The procedure is performed if adequate tissue perfusion does not return following an escharotomy.
   c. Fasciotomy is performed in the operating room with the client under
K. Wound care

1. Description: Cleansing, debridement, and dressing of burn wounds

2. Hydrotherapy
   a. Wounds are cleansed by showering on a special table, or washing small areas of wound at the bedside.
   b. Hydrotherapy occurs for 30 minutes or less to prevent increased sodium loss through the burn wound, heat loss, pain, and stress.
   c. Client should be premedicated before procedure.
   d. Hydrotherapy is not used for clients who are hemodynamically unstable or those with new skin grafts.
   e. Care is taken to minimize bleeding and maintain body temperature during the procedure.
   f. Prescribed antimicrobial agents are applied after hydrotherapy.

3. Debridement
   a. Debridement is removal of eschar or necrotic tissue to prevent bacterial proliferation under the eschar and to promote wound healing.
   b. Debridement may be mechanical, enzymatic, or surgical.
   c. Deep partial-thickness burns or deep full-thickness burns: Wound is cleansed and debrided, and topical antimicrobial agents are applied once or twice daily.

4. Wound closure
   a. Wound closure prevents infection and loss of fluid.
   b. Closure promotes healing.
   c. Closure prevents contractures.
   d. Wound closure is performed usually on day 5 to 21 following the injury,
depending on the extent of the burn.

5. Wound coverings (Box 69-10)

6. Autografting
   a. Autografting is the surgical removal of a thin layer of the client’s own unburned skin, which then is applied to the excised burn wound.
   b. Autografting provides permanent wound coverage.
   c. Autografting is performed in the operating room under anesthesia.
   d. Monitor for bleeding following the graft procedure, because bleeding beneath an autograft can prevent adherence.
   e. If prescribed, small amounts of blood or serum can be removed by gently rolling the fluid from the center of the graft to the periphery with a sterile gauze pad, where it can be absorbed.
   f. For large accumulations of blood, the PHCP may aspirate the blood using a small-gauge needle and syringe.
   g. Autografts are immobilized following surgery for 3 to 7 days to allow time to adhere and attach to the wound bed.
   h. Position the client for immobilization and elevation of the graft site to prevent movement and shearing of the graft.

7. Care of the graft site
   a. Elevate and immobilize the graft site.
   b. Keep the site free from pressure.
   c. Avoid weight-bearing.
   d. When the graft takes, if prescribed, roll a cotton-tipped applicator over the graft to remove exudate, because exudate can lead to infection and prevent graft adherence.
   e. Monitor for foul-smelling drainage, increased temperature, increased white blood cell count, hematoma formation, and fluid accumulation.
   f. Instruct the client to avoid using fabric
softeners and harsh detergents in the laundry.
g. Instruct the client to lubricate the healing skin with prescribed agents.
h. Instruct the client to protect the affected area from sunlight.
i. Instruct the client to use splints and support garments as prescribed.

8. Care of the donor site
   a. Method of care varies, depending on the PHCP’s preference.
b. A nonadherent gauze dressing may be applied at the time of the surgery to maintain pressure and stop any oozing; covering the site decreases discomfort from exposed nerve endings; always check the surgeon’s preference.
c. The PHCP may prescribe site treatment with gauze impregnated with petrolatum or with a biosynthetic dressing.
d. Keep the donor site clean, dry, and free from pressure.
e. Prevent the client from scratching the donor site.
f. Apply lubricating lotions to soften the area and reduce the itching after the donor site is healed.
g. Donor site can be reused once healing has occurred (heals spontaneously within 7 to 14 days with proper care).

L. Rehabilitative phase (see Table 69-7)
   1. Description: Rehabilitation is the final phase of burn care.

2. Goals
   a. Promote wound healing.
   b. Minimize deformities.
   c. Increase strength and function.
   d. Provide emotional support.

M. Physical therapy
   1. An individualized program of splinting, positioning, exercises, ambulation, and activities of daily living is implemented early in the acute phase of recovery to maximize functional and cosmetic outcomes.
2. Perform range-of-motion exercises as prescribed to reduce edema and maintain strength and joint function.
3. Ambulate the client as prescribed to maintain the strength of the lower extremities.
4. Apply splints as prescribed to maintain proper joint position and prevent contractures.
   a. Static splints immobilize the joint and are applied for periods of immobilization, during sleeping, and for clients who cannot maintain proper positioning,
   b. Dynamic splints exercise the affected joint.
   c. Avoid pressure to skin areas when applying splints, which could lead to further tissue and nerve damage.
5. Scarring is controlled by elastic wraps and bandages that apply continuous pressure to the healing skin during the time in which the skin is vulnerable to shearing.
6. Anti–burn scar support garments are usually prescribed to be worn 23 hours a day until the burn scar tissue has matured, which takes 18 to 24 months.

VI. Complex Hematological and Oncological Problems

A. Oncological emergencies: include sepsis and disseminated intravascular coagulation (DIC), syndrome of inappropriate antidiuretic hormone (SIADH), spinal cord compression, hypercalcemia, and superior vena cava syndrome

B. Sepsis and DIC

1. Description: The client with cancer is at increased risk for infection, particularly gram-negative organisms, in the bloodstream (sepsis or septicemia) and DIC, a life-threatening hematological problem frequently associated with sepsis.

2. Interventions
   a. Prevent the complication through early identification of clients at high risk for sepsis and DIC.
   b. Maintain strict aseptic technique with the immunocompromised client and monitor closely for infection and signs of bleeding.
   c. Administer antibiotics intravenously as prescribed.
   d. Administer anticoagulants as prescribed during the early phase of
DIC.

e. Administer cryoprecipitated clotting factors, as prescribed, when DIC progresses and hemorrhage is the primary problem.

\[\text{Notify the PHCP immediately if signs of an oncological emergency occur.}\]

C. SIADH

1. Description

a. Tumors can produce, secrete, or stimulate substances that mimic antidiuretic hormone.

b. Mild symptoms include weakness, muscle cramps, loss of appetite, and fatigue; serum sodium levels range from 115 to 120 mEq/L (115 to 120 mmol/L).

c. More serious signs and symptoms relate to water intoxication and include weight gain, personality changes, confusion, and extreme muscle weakness.

d. As the serum sodium level approaches 110 mEq/L (110 mmol/L), seizures, coma, and eventually death will occur, unless the condition is treated rapidly.

2. Interventions

a. Initiate fluid restriction and increased sodium intake as prescribed.

b. As prescribed, administer an antagonist to antidiuretic hormone.

c. Monitor serum sodium levels.

d. Treat the underlying cause with chemotherapy or radiation to reduce the tumor.

D. Spinal cord compression

1. Description

a. Spinal cord compression occurs when a tumor directly enters the spinal cord or when the vertebral column collapses from tumor entry, impinging on the spinal cord.

b. Spinal cord compression causes back pain, usually before neurological deficits occur.
c. Neurological deficits relate to the spinal level of compression and include numbness; tingling; loss of urethral, vaginal, and rectal sensation; and muscle weakness.

2. Interventions
   a. Early recognition: Assess for back pain and neurological deficits.
   b. Administer high-dose corticosteroids to reduce swelling around the spinal cord and relieve symptoms.
   c. Prepare the client for immediate radiation and/or chemotherapy to reduce the size of the tumor and relieve compression.
   d. Surgery may need to be performed to remove the tumor and relieve the pressure on the spinal cord.
   e. Instruct the client in the use of neck or back braces if they are prescribed.

E. Hypercalcemia
   1. Description
      a. Hypercalcemia is a late manifestation of extensive malignancy that occurs most often with bone metastasis, when the bone releases calcium into the bloodstream.
      b. Decreased physical mobility contributes to or worsens hypercalcemia.
      c. Early signs include fatigue, anorexia, nausea, vomiting, constipation, and polyuria.
      d. More serious signs and symptoms include severe muscle weakness, diminished deep tendon reflexes, paralytic ileus, dehydration, and changes in the electrocardiogram.
   2. Interventions
      a. Monitor serum calcium level and ECG changes.
      b. Administer oral or parenteral fluids as prescribed.
      c. Administer medications that lower the calcium level and control nausea and vomiting as prescribed.
      d. Prepare the client for dialysis if the condition becomes life-threatening or is accompanied by renal impairment.
e. Encourage walking to prevent breakdown of bone.

F. Superior vena cava syndrome
   1. Description
      a. Superior vena cava (SVC) syndrome occurs when the SVC is compressed or obstructed by tumor growth (commonly associated with lung cancer and lymphoma).
      b. Signs and symptoms result from blockage of blood flow in the venous system of the head, neck, and upper trunk.
      c. Early signs and symptoms generally occur in the morning and include edema of the face, especially around the eyes, and tightness of the shirt or blouse collar (Stokes’ sign).
      d. As the condition worsens, edema in the arms and hands, dyspnea, erythema of the upper body, swelling of the veins in the chest and neck, and epistaxis occur.
      e. Life-threatening signs and symptoms include airway obstruction, hemorrhage, cyanosis, mental status changes, decreased cardiac output, and hypotension.
   2. Interventions
      a. Assess for early signs and symptoms of SVC syndrome.
      b. Place the client in semi-Fowler’s position and administer corticosteroids and diuretics as prescribed.
      c. Prepare the client for high-dose radiation therapy to the mediastinal area, and possible surgery to insert a metal stent in the vena cava.

G. Tumor lysis syndrome
   1. Description
      a. Tumor lysis syndrome occurs when large quantities of tumor cells are destroyed rapidly and intracellular components such as potassium and uric acid are released into the bloodstream faster than the body can eliminate them.
      b. Tumor lysis syndrome can indicate that
cancer treatment is destroying tumor cells; however, if left untreated, it can cause severe tissue damage and death.

c. Hyperkalemia, hyperphosphatemia with resultant hypocalcemia, and hyperuricemia occur; hyperuricemia can lead to acute kidney injury.

2. Interventions
   a. Encourage oral hydration; IV hydration may be prescribed; monitor renal function and intake and output, and ensure that the client is on a renal diet low in potassium and phosphorus.
   b. Administer diuretics to increase the urine flow through the kidneys as prescribed.
   c. Administer medications that increase the excretion of purines, such as allopurinol, as prescribed.
   d. Prepare to administer IV infusion of glucose and insulin to treat hyperkalemia.
   e. Prepare the client for dialysis if hyperkalemia and hyperuricemia persist despite treatment.

VII. Complex Endocrine Problems
   A. Diabetic ketoacidosis (DKA)
      1. Description (Fig. 69-19)
         a. Diabetic ketoacidosis is a life-threatening complication of type 1 diabetes mellitus that develops when a severe insulin deficiency occurs.
         b. The main clinical manifestations include hyperglycemia, dehydration, ketosis, and acidosis.

VII. Complex Endocrine Problems
   A. Diabetic ketoacidosis (DKA)
      1. Description (Fig. 69-19)
         a. Diabetic ketoacidosis is a life-threatening complication of type 1 diabetes mellitus that develops when a severe insulin deficiency occurs.
         b. The main clinical manifestations include hyperglycemia, dehydration, ketosis, and acidosis.
      2. Assessment (Table 69-9)
      3. Interventions
         a. Restore circulating blood volume and protect against cerebral, coronary, and renal hypoperfusion.
         b. Treat dehydration with rapid IV infusions of 0.9% or 0.45% NS as prescribed; dextrose is added to IV fluids when the blood glucose level reaches 250 to 300 mg/dL (14 to
17 mmol/L). Too rapid administration of IV fluids; use of the incorrect types of IV fluids, particularly hypotonic solutions; and correcting the blood glucose level too rapidly can lead to cerebral edema.

c. Treat hyperglycemia with insulin administered intravenously as prescribed.

d. Correct electrolyte imbalances (potassium level may be elevated as a result of dehydration and acidosis).

e. Monitor potassium level closely, because when the client receives treatment for the dehydration and acidosis, the serum potassium level will decrease and potassium replacement may be required.

f. Cardiac monitoring should be in place for the client with DKA due to risks associated with abnormal serum potassium levels.

4. Insulin IV administration

a. Use short-duration insulin only.

b. An IV bolus dose of short-duration regular U-100 insulin (usually 5 to 10 units) may be prescribed before a continuous infusion is begun.

c. The prescribed IV dose of insulin for continuous infusion is prepared in 0.9% or 0.45% NS as prescribed.

d. Always place the insulin infusion on an IV infusion controller.

e. Insulin is infused continuously until subcutaneous administration resumes, to prevent a rebound of the blood glucose level.

f. Monitor vital signs.

g. Monitor urinary output and monitor for signs of fluid overload.

h. Monitor potassium and glucose levels and for signs of increased intracranial pressure (ICP).

i. The potassium level will fall rapidly within the first hour of treatment as the dehydration and the acidosis are treated.
j. Potassium is administered intravenously in a diluted solution as prescribed; ensure adequate renal function before administering potassium.

5. Client education (Box 69-11)

Monitor the client being treated for DKA closely for signs of increased intracranial pressure. If the blood glucose level falls too far or too fast before the brain has time to equilibrate, water is pulled from the blood to the cerebrospinal fluid and the brain, causing cerebral edema and increased ICP.

B. Hyperosmolar hyperglycemic syndrome (HHS)

1. Description
   a. Extreme hyperglycemia occurs without ketosis or acidosis.
   b. The syndrome occurs most often in individuals with type 2 diabetes mellitus.
   c. The major difference between HHS and DKA is that ketosis and acidosis do not occur with HHS; enough insulin is present with HHS to prevent the breakdown of fats for energy, thus preventing ketosis.

2. Assessment (see Table 69-9)

3. Interventions
   a. Treatment is similar to that for DKA.
   b. Treatment includes fluid replacement, correction of electrolyte imbalances, and insulin administration.
   c. Fluid replacement in the older client must be done very carefully because of the potential for heart failure.
   d. Insulin plays a less critical role in the treatment of HHS than it does in the treatment of DKA, because ketosis and acidosis do not occur; rehydration alone may decrease glucose levels.

VIII. Complex Gastrointestinal Problems
A. Esophageal varices
   1. Description
   a. Dilated and tortuous veins in the submucosa of the esophagus.
b. Caused by portal hypertension, often
associated with liver cirrhosis; are at
high risk for rupture if portal
circulation pressure rises

c. Bleeding varices are an emergency.
d. The goal of treatment is to control
bleeding, prevent complications, and
prevent the recurrence of bleeding.

2. Assessment

a. Hematemesis
b. Melena
c. Ascites
d. Jaundice
e. Hepatomegaly and splenomegaly
f. Dilated abdominal veins
g. Signs of shock

Rupture and resultant hemorrhage of
esophageal varices is the primary concern because
it is a life-threatening situation.

3. Interventions

a. Monitor vital signs.
b. Elevate the head of the bed.
c. Monitor for orthostatic hypotension.
d. Monitor lung sounds and for the
presence of respiratory distress.
e. Administer oxygen as prescribed to
prevent tissue hypoxia.
f. Monitor level of consciousness.
g. Maintain NPO status.
h. Administer fluids intravenously as
prescribed to restore fluid volume and
electrolyte imbalances; monitor intake
and output.
i. Monitor hemoglobin and hematocrit
values and coagulation factors.
j. Administer blood transfusions or
clotting factors as prescribed.
k. Assist in inserting an NG tube or a
balloon tamponade as prescribed;
balloon tamponade is not used
frequently because it is very
uncomfortable for the client and its use
is associated with complications.
l. Prepare to assist with administering
medications to induce vasoconstriction and reduce bleeding.

m. Instruct the client to avoid activities that will initiate vasovagal responses.

n. Prepare the client for endoscopic procedures or surgical procedures as prescribed.

4. Endoscopic injection (sclerotherapy)
   a. The procedure involves the injection of a sclerosing agent into and around bleeding varices.
   b. Complications include chest pain, pleural effusion, aspiration pneumonia, esophageal stricture, and perforation of the esophagus.

5. Endoscopic variceal ligation
   a. The procedure involves ligation of the varices with an elastic rubber band.
   b. Sloughing, followed by superficial ulceration, occurs in the area of ligation within 3 to 7 days.

6. Shunting procedures
   a. Description: These procedures shunt blood away from the esophageal varices
   b. Portacaval shunting involves anastomosis of the portal vein to the inferior vena cava, diverting blood from the portal system to the systemic circulation (Fig. 69-20).
   c. Distal splenorenal shunt: The shunt involves anastomosis of the splenic vein to the left renal vein; the spleen conducts blood from the high-pressure varices to the low-pressure renal vein (see Fig. 69-20).
   d. Mesocaval shunting involves a side anastomosis of the superior mesenteric vein to the proximal end of the inferior vena cava.
   e. Transjugular intrahepatic portosystemic shunt (TIPS): This procedure uses the normal vascular anatomy of the liver to create a shunt with the use of a metallic stent; the shunt is between the portal and systemic venous system in the liver and is aimed at relieving portal hypertension.
B. Gastrointestinal (GI) bleeding
   1. Description: Bleeding that occurs at some area in the GI tract; classified into upper GI bleeding or lower GI bleeding.
   2. Causes of upper GI bleeding include peptic ulcer disease, stress-related erosive syndrome, esophageal or gastric varices, tearing of the GI tract, esophagitis, neoplasm, aortoenteric fistula, and angiodysplasia.
   3. Causes of lower GI bleeding include diverticulosis, angiodysplasia, neoplasm, inflammatory bowel disease, trauma, infectious colitis, radiation colitis, ischemia, aortoenteric fistula, and hemorrhoids.
   4. GI bleeding, or hemorrhage, is a potentially life-threatening emergency condition.
   5. Assessment
      a. Hematemesis
      b. Hematochezia
      c. Melena
      d. Decreased hemoglobin and hematocrit levels (may take 24 to 72 hours for the change to occur in acute blood loss)
   6. Diagnosis
      a. Endoscopy once the client is hemodynamically stabilized
      b. Tagged red blood cell scanning, angiography, or both may be used to locate the source of bleeding.
   7. Interventions
      a. The goal is to stop the bleeding and determine the cause of bleeding.
      b. Fluid resuscitation to achieve hemodynamic stability is necessary.
      c. Correction of hypercoagulability if indicated
      d. Therapeutic procedures to control or stop the bleeding
      e. Medications to suppress or neutralize gastric acids, including histamine-2 antagonists and proton pump inhibitors
      f. Note that these medications may place the client at risk for bacterial colonization and associated infections.
      g. Surgery may be used for a client who continues to be hemodynamically stable despite fluid resuscitation.

IX. Complex Respiratory Problems
   A. Respiratory treatments
1. Chest physiotherapy (CPT)
   a. Description: Percussion, vibration, and postural drainage techniques are performed over the thorax to loosen secretions in the affected area of the lungs and move them into more central airways.
   b. Contraindications and interventions (Box 69-12)

B. Oxygen

1. Supplemental oxygen delivery systems (Table 69-10)
   a. Nasal cannula for low flow: Used for the client with chronic airflow limitation and for long-term oxygen use (Fig. 69-21)
   b. Nasal high-flow (NHF) respiratory therapy: Used for hypoxemic clients in mild to moderate respiratory distress (Box 69-13)
   c. Simple face mask: Used for short-term oxygen therapy or to deliver oxygen in an emergency (Fig. 69-22)
   d. Venturi mask: Used for clients at risk for or experiencing acute respiratory failure (Fig. 69-23)
   e. Partial rebreather mask: Useful when the oxygen concentration needs to be raised; not usually prescribed for a client with chronic obstructive pulmonary disease (COPD)
   f. Nonrebreather mask: Most frequently used for the client with a deteriorating respiratory status who might require intubation (Fig. 69-24)
   g. Tracheostomy collar and T-bar or T-piece: Tracheostomy collar is used to deliver high humidity and the desired oxygen to the client with a tracheostomy; the T-bar or T-piece is used to deliver the desired FiO₂ to the client with a tracheostomy, laryngectomy, or endotracheal tube (Fig. 69-25).
   h. Face tent: Used instead of a tight-fitting mask for the client who has facial
2. Continuous positive airway pressure (CPAP) and bilevel positive airway pressure (BiPAP) (see Section IX, C, 7 [Noninvasive positive pressure ventilation or BiPAP] for more information on BiPAP)
   a. CPAP maintains a set positive airway pressure during inspiration and expiration; beneficial in clients who have obstructive sleep apnea or acute exacerbations of COPD.
   b. BiPAP provides positive airway pressure during inspiration and ceases airway support during expiration; there is only enough pressure provided during expiration to keep the airways open; usually used if CPAP is ineffective.
   c. Both CPAP and BiPAP improve oxygenation through airway support.

3. General interventions
   a. Assess color, pulse oximetry reading, and vital signs before and during treatment.
   b. Place an Oxygen in Use sign at the client’s bedside.
   c. Assess for the presence of chronic lung problems.
   d. Humidify the oxygen if indicated.
   e. For specific considerations for each supplemental oxygen delivery system, see Table 69-10.

A client who is hypoxemic and has chronic hypercapnia may require low levels of oxygen delivery at 1 to 2 L/minute, because a low arterial oxygen level is the client’s primary drive for breathing; always check PHCP’s prescriptions.

C. Mechanical ventilation
   1. Types: include pressure-cycled ventilator, time-cycled ventilator, volume-cycled ventilator, and microprocessor ventilator
   2. Pressure-cycled ventilator: The ventilator pushes air into the lungs until a specific airway pressure is reached; it is used for short periods, as in the postanesthesia care unit.
   3. Time-cycled ventilator: The ventilator pushes air into
the lungs until a preset time has elapsed; it is used for the pediatric or neonatal client.

4. Volume-cycled ventilator
   a. The ventilator pushes air into the lungs until a preset volume is delivered.
   b. A constant tidal volume is delivered regardless of the changing compliance of the lungs and chest wall or the airway resistance in the client or ventilator.

5. Microprocessor ventilator
   a. A computer or microprocessor is built into the ventilator to allow continuous monitoring of ventilatory functions, alarms, and client parameters.
   b. This type of ventilator is more responsive to clients who have severe lung disease or require prolonged weaning.

6. Modes of ventilation: include noninvasive positive pressure ventilation or BiPAP, controlled, assist-controlled, and synchronized intermittent mandatory ventilation (SIMV)

7. Noninvasive positive pressure ventilation or BiPAP (Fig. 69-26)
   a. Ventilatory support given without using an invasive artificial airway (endotracheal tube or tracheostomy tube); orofacial masks and nasal masks are used instead.
   b. An inspiratory positive airway pressure (IPAP) and an expiratory positive airway pressure (EPAP) are set on a large ventilator or a small flow generator ventilator with a desired pressure support and positive end-expiratory pressure (PEEP) level. This allows more air to move into and out of the lungs without the normal muscular activity needed to do so.
   c. Can be used in certain situations of COPD distress, heart failure, asthma, pulmonary edema, and hypercapnic respiratory failure.

A bag-valve resuscitation mask should be
available at the bedside for all clients receiving mechanical ventilation.

8. Controlled
   a. The client receives a set tidal volume at a set rate.
   b. Used for clients who cannot initiate respiratory effort
   c. Least used mode; if the client attempts to initiate a breath, the ventilator locks out the client’s inspiratory effort.

9. Assist-control
   a. Tidal volume and ventilatory rate are preset on the ventilator.
   b. The ventilator takes over the work of breathing for the client.
   c. The ventilator is programmed to respond to the client’s inspiratory effort if the client does initiate a breath.
   d. The ventilator delivers the preset tidal volume when the client initiates a breath while allowing the client to control the rate of breathing.
   e. If the client’s spontaneous ventilatory rate increases, the ventilator continues to deliver a preset tidal volume with each breath, which may cause hyperventilation and respiratory alkalosis.

10. SIMV
    a. Similar to assist-control ventilation in that the tidal volume and ventilatory rate are preset on the ventilator
    b. Allows the client to breathe spontaneously at her or his own rate and tidal volume between the ventilator breaths
    c. Can be used as a primary ventilatory mode or as a weaning mode
    d. When SIMV is used as a weaning mode, the number of SIMV breaths is decreased gradually, and the client gradually resumes spontaneous breathing.

11. Ventilator controls and settings (Table 69-11)
12. Interventions

For a client receiving mechanical ventilation, always assess the client first and then assess the ventilator.

a. Assess vital signs, lung sounds, respiratory status, and breathing patterns (the client will never breathe at a rate lower than the rate set on the ventilator).
b. Monitor skin color, particularly in the lips and nailbeds.
c. Monitor the chest for bilateral expansion.
d. Obtain pulse oximetry readings.
e. Monitor ABG results.
f. Assess the need for suctioning and observe the type, color, and amount of secretions.
g. Assess ventilator settings.
h. Assess the level of water in the humidifier and the temperature of the humidification system, because extremes in temperature can damage the mucosa in the airway.
i. Ensure that the alarms are set.
j. If a cause for an alarm cannot be determined, ventilate the client manually with a bag-valve resuscitation mask until the problem is corrected.
k. Empty the ventilator tubing when moisture collects.
l. Turn the client at least every 2 hours or get the client out of bed, as prescribed, to prevent complications of immobility.
m. Have resuscitation equipment available at the bedside.

13. Causes of ventilator alarms (Box 69-14)

14. Alarm safety and alarm fatigue

a. It is the responsibility of the nurse to be alert to the sound of an alarm, because this signals a client problem.
b. The nurse needs to respond promptly to an alarm and immediately assess the client.

c. According to The Joint Commission (TJC), the most common contributing factor related to alarm-related sentinel events is alarm fatigue, which results when the numerous alarms and the resulting noise tends to desensitize the nursing staff and cause them to ignore alarms or even disable them.

d. Some recommendations of TJC include establishing alarm safety as a facility policy, identifying default alarm settings, identifying the most important alarms to manage, establishing policies and procedures for managing alarms, and staff education.

e. For additional information, refer to www.pwrnewmedia.com/2013/joint_commission/medical_alarm_safety/downloads/SEA_50_alarms.pdf

15. Complications

a. Hypotension caused by the application of positive pressure, which increases intrathoracic pressure and inhibits blood return to the heart

b. Respiratory complications such as pneumothorax or subcutaneous emphysema as a result of positive pressure

c. Gastrointestinal alterations such as stress ulcers

d. Malnutrition if nutrition is not maintained

e. Infections

f. Muscular deconditioning

g. Ventilator dependence or inability to wean

h. Bradycardia as a result of increased intrathoracic pressure or activated vagal response
16. Weaning: Process of going from ventilator dependence to spontaneous breathing; methods include SIMV, T-piece, and pressure support

17. SIMV
   a. The client breathes between the preset breaths per minute rate of the ventilator.
   b. The SIMV rate is decreased gradually until the client is breathing on her or his own without the use of the ventilator.

18. T-piece
   a. The client is taken off the ventilator and the ventilator is replaced with a T-piece or CPAP, which delivers humidified oxygen.
   b. The client is taken off the ventilator for short periods initially and allowed to breathe spontaneously.
   c. Weaning progresses as the client is able to tolerate progressively longer periods off the ventilator.

19. Pressure support
   a. Pressure support is a predetermined pressure set on the ventilator to assist the client in respiratory effort.
   b. As weaning continues, the amount of pressure is decreased gradually.
   c. With pressure support, pressure may be maintained while the preset breaths per minute of the ventilator are decreased gradually.

D. Rib fracture
   1. Results from direct blunt chest trauma and causes a potential for intrathoracic injury, such as pneumothorax, hemothorax, or pulmonary contusion
   2. Pain with movement, deep breathing, and coughing results in impaired ventilation and inadequate clearance of secretions.
   3. Assessment
      a. Pain and tenderness at the injury site that increases with inspiration
      b. Shallow respirations
      c. Client splints chest
d. Fractures noted on chest x-ray

4. Interventions
   a. Note that the ribs usually reunite spontaneously.
   b. Place the client in a Fowler’s position.
   c. Administer pain medication as prescribed to maintain adequate ventilatory status.
   d. Monitor for increased respiratory distress.
   e. Instruct the client to self-splint with the hands, arms, or a pillow.
   f. Open reduction and internal fixation of the ribs (rib plating) may be done.
   g. Prepare the client for an intercostal nerve block as prescribed if the pain is severe.

E. Flail chest
   1. Occurs from blunt chest trauma associated with accidents, which may result in hemothorax and rib fractures.
   2. The loose segment of the chest wall becomes paradoxical to the expansion and contraction of the rest of the chest wall.

3. Assessment
   a. Paradoxical respirations (inward movement of a segment of the thorax during inspiration with outward movement during expiration)
   b. Severe pain in the chest
   c. Dyspnea
   d. Cyanosis
   e. Tachycardia
   f. Hypotension
   g. Tachypnea, shallow respirations
   h. Diminished breath sounds

4. Interventions
   a. Maintain the client in a Fowler’s position.
   b. Administer oxygen as prescribed.
c. Monitor for increased respiratory distress.
d. Encourage coughing and deep breathing.
e. Administer pain medication as prescribed.
f. Maintain bed rest and limit activity to reduce oxygen demands.
g. Open reduction and internal fixation of the ribs (rib plating) may be done.
h. Prepare for intubation with mechanical ventilation, with PEEP for severe flail chest associated with respiratory failure and shock.

F. Pulmonary contusion

1. Characterized by interstitial hemorrhage associated with intra-alveolar hemorrhage, resulting in decreased pulmonary compliance

2. The major complication is acute respiratory distress syndrome.

3. Assessment
   a. Dyspnea
   b. Restlessness
   c. Increased bronchial secretions
   d. Hypoxemia
   e. Hemothysis
   f. Decreased breath sounds
   g. Crackles and wheezes

4. Interventions
   a. Maintain a patent airway and adequate ventilation.
   b. Place the client in a Fowler’s position.
   c. Administer oxygen as prescribed.
   d. Monitor for increased respiratory distress.
   e. Maintain bed rest and limit activity to reduce oxygen demands.
   f. Prepare for mechanical ventilation with PEEP if required.

G. Pneumothorax (Fig. 69-27)

1. Accumulation of atmospheric air in the pleural space, which results in a rise in intrathoracic pressure and
reduced vital capacity
2. The loss of negative intrapleural pressure results in collapse of the lung.
3. A spontaneous pneumothorax occurs with the rupture of a pulmonary bleb, or small air-containing spaces deep in the lung.
4. An open pneumothorax occurs when an opening through the chest wall allows the entrance of positive atmospheric air pressure into the pleural space.
5. A tension pneumothorax occurs from a blunt chest injury or from mechanical ventilation with PEEP when a buildup of positive pressure occurs in the pleural space.
6. Assessment (Box 69-15)
7. Interventions
a. Diagnosis of pneumothorax is made by chest x-ray.
b. Apply a nonporous dressing over an open chest wound.
c. Administer oxygen as prescribed.
d. Place the client in a Fowler’s position.
e. Prepare for chest tube placement, which will remain in place until the lung has expanded fully (see section IV, O, for information on chest tubes).
f. Monitor the chest tube drainage system.
g. Monitor for subcutaneous emphysema.

Clients with a respiratory disorder should be positioned with the head of the bed elevated.

H. Acute respiratory failure
1. Occurs when insufficient oxygen is transported to the blood or inadequate carbon dioxide is removed from the lungs and the client’s compensatory mechanisms fail
2. Causes include a mechanical abnormality of the lungs or chest wall, a defect in the respiratory control center in the brain, or an impairment in the function of the respiratory muscles.
3. In oxygenation failure, or hypoxemic respiratory failure, oxygen may reach the alveoli but cannot be absorbed or used properly, resulting in a
PaO$_2$ lower than 60 mm Hg, arterial oxygen saturation (SaO$_2$) lower than 90%, or partial pressure of arterial carbon dioxide (PaCO$_2$) greater than 50 mm Hg occurring with acidemia.

4. Respiratory failure can be hypoxemic, hypercapnic, or both. Inadequate gas exchange is the mechanism behind failure. Arterial oxygen, carbon dioxide, or both are not kept at normal levels, resulting in failure.

5. Many clients experience both hypoxemic and hypercapnic respiratory failure and retained carbon dioxide in the alveoli displaces oxygen, contributing to the hypoxemia.

6. Manifestations of respiratory failure are related to the extent and rapidity of change in PaO$_2$ and PaCO$_2$.

7. Assessment
   a. Dyspnea
   b. Restlessness
   c. Confusion
   d. Tachycardia
   e. Hypertension
   f. Dysrhythmias
   g. Decreased level of consciousness
   h. Alterations in respirations and breath sounds
   i. Headache (less common)

8. Interventions
   a. Identify and treat the cause of the respiratory failure.
   b. Administer oxygen to maintain the PaO$_2$ level higher than 60 to 70 mm Hg.
   c. Place the client in a Fowler’s position.
   d. Encourage deep breathing.
   e. Administer bronchodilators as prescribed.
   f. Prepare the client for mechanical ventilation if supplemental oxygen cannot maintain acceptable PaO$_2$ and PaCO$_2$ levels.

I. Acute respiratory distress syndrome

1. A form of acute respiratory failure that occurs as a complication caused by a diffuse lung injury or critical illness and leads to extravascular lung fluid.
2. The major site of injury is the alveolar capillary
membrane.

3. The interstitial edema causes compression and obliteration of the terminal airways and leads to reduced lung volume and compliance.

4. The ABG levels identify respiratory acidosis and hypoxemia that do not respond to an increased percentage of oxygen.

5. The chest x-ray shows bilateral interstitial and alveolar infiltrates; interstitial edema may not be noted until there is a 30% increase in fluid content.

6. Causes include sepsis, fluid overload, shock, trauma, neurological injuries, burns, DIC, drug ingestion, aspiration, and inhalation of toxic substances.

7. Assessment
   a. Tachypnea
   b. Dyspnea
   c. Decreased breath sounds
   d. Deteriorating ABG levels
   e. Hypoxemia despite high concentrations of delivered oxygen
   f. Decreased pulmonary compliance
   g. Pulmonary infiltrates

8. Interventions
   a. Identify and treat the cause of the acute respiratory distress syndrome.
   b. Administer oxygen as prescribed.
   c. Place the client in a Fowler’s position.
   d. Restrict fluid intake as prescribed.
   e. Provide respiratory treatments as prescribed.
   f. Administer diuretics, anticoagulants, or corticosteroids as prescribed.
   g. Prepare the client for intubation and mechanical ventilation using PEEP.
X. Complex Cardiovascular Problems

A. Cardiogenic shock

1. Cardiogenic shock is failure of the heart to pump adequately, thereby reducing cardiac output and compromising tissue perfusion.
2. Necrosis of more than 40% of the left ventricle, usually as a result of occlusion of major coronary vessels, leads to cardiogenic shock.
3. The goal of treatment is to maintain tissue oxygenation and perfusion and improve the pumping ability of the heart.
4. Assessment
   a. Hypotension: BP lower than 90 mm Hg systolic or 30 mm Hg lower than the client’s baseline
   b. Urine output lower than 30 mL/hr
   c. Cold, clammy skin
   d. Poor peripheral pulses
   e. Tachycardia, tachypnea
   f. Pulmonary congestion
   g. Disorientation, restlessness, and confusion
   h. Continuing chest discomfort
5. Interventions
   a. Administer oxygen as prescribed.
   b. Administer morphine sulfate intravenously as prescribed to decrease pulmonary congestion and relieve chest pain.
   c. Prepare for intubation and mechanical ventilation.
   d. Administer diuretics and nitrates as prescribed while monitoring the BP constantly.
   e. Administer vasopressors and positive inotropes as prescribed to maintain organ perfusion.
   f. Prepare the client for insertion of an intra-aortic balloon pump, if prescribed, to improve coronary artery perfusion and improve cardiac output.
   g. Prepare the client for immediate reperfusion procedures such as percutaneous transluminal coronary
angioplasty (PTCA) or coronary artery bypass graft.
h. Monitor arterial blood gas levels and prepare to treat imbalances.
i. Monitor urinary output.
j. Assist with the insertion of a pulmonary artery (Swan-Ganz) catheter to assess degree of heart failure (Fig. 69-28).

B. Hemodynamic monitoring: includes central venous pressure (CVP), pulmonary artery pressures, and mean arterial pressure (MAP) (see Fig. 69-28)

C. Central venous pressure (CVP)

1. The CVP is the pressure within the superior vena cava; it reflects the pressure under which blood is returned to the superior vena cava and right atrium.
2. The CVP is measured with a central venous line in the superior vena cava.
3. Normal CVP pressure ranges between approximately 3 to 8 mm Hg.
4. An elevated CVP indicates an increase in blood volume as a result of sodium and water retention, excessive IV fluids, alterations in fluid balance, or kidney failure.
5. A decreased CVP indicates a decrease in circulating blood volume and may be a result of fluid imbalances, hemorrhage, or severe vasodilation, with pooling of blood in the extremities that limits venous return.

D. Measuring CVP

1. The right atrium is located at the midaxillary line at the fourth intercostal space; the zero point on the transducer needs to be at the level of the right atrium.
2. The client needs to be relaxed; activity that increases intrathoracic pressure, such as coughing or straining, will cause false increases in the readings.
3. If the client is on a ventilator, the reading should be taken at the point of end-expiration.
4. To maintain patency of the central venous line, a continuous small amount of fluid is delivered under pressure.

E. Pulmonary artery pressures

1. A pulmonary artery catheter is used to measure right heart and indirect left heart pressures.
2. Pulmonary artery wedge pressure (PAWP) is also known as pulmonary artery occlusive pressure
(PAOP) and as pulmonary capillary wedge pressure (PCWP).

3. The measurement is obtained during momentary balloon inflation of the pulmonary artery catheter and reflects left ventricular end-diastolic pressure.

4. PAWP normally ranges between approximately 4 to 12 mm Hg; elevations may indicate left ventricular failure, hypervolemia, mitral regurgitation, or intracardiac shunt, whereas decreases may indicate hypovolemia or afterload reduction.

5. Normal RA pressure ranges between approximately 2 to 6 mm Hg; increases occur with right ventricular failure, whereas decreases may indicate hypovolemia.

6. Normal pulmonary artery pressure (PAP) ranges between approximately 15 to 30 mm Hg systolic/8 to 15 mm Hg diastolic.

F. Mean arterial pressure (MAP)
1. An approximation of the average pressure in the systemic circulation throughout the cardiac cycle
2. MAP ranges between approximately 70 to 105 mm Hg.

H. Advanced management of pulseless rhythms

1. Initial Steps
   a. Begin CPR; attach the monitor or defibrillator.
   b. Determine whether the rhythm is shockable or nonshockable.
   c. Shockable pulseless rhythms include ventricular fibrillation and ventricular tachycardia.
   d. Nonshockable pulseless rhythms include asystole and pulseless electrical activity (PEA).

2. Shockable rhythms: ventricular fibrillation and ventricular tachycardia
   a. After beginning CPR, attaching the monitor, and determining the rhythm, shock at 100 to 200 J as an initial dose that is increased if biphasic; use 360 J if monophasic.
   b. Continue CPR and establish an IV or intraosseus (IO) access if not previously done.
c. Analyze the rhythm; if shockable, shock again.
d. Prepare to administer epinephrine 1 mg every 3 to 5 minutes as prescribed.
e. An advanced airway should be considered, and capnography should be used to determine CPR quality.
f. Continue CPR, analyze the rhythm, and shock if the rhythm is shockable. If the rhythm becomes unshockable, follow the nonshockable rhythms approach.
g. As prescribed, prepare to administer amiodarone 300 mg IV/IO bolus, followed by 150 mg IV/IO if indicated at the next appropriate cycle.
h. Consider reversible causes, which include hypoxia, hypovolemia, hydrogen ions or acidosis, hyperkalemia or hypokalemia (5 Hs) and tension pneumothorax, tamponade, toxins, thrombosis (pulmonary embolus), or thrombosis (acute coronary syndrome; 5 Ts).
i. Continue to cycle through the above steps until return of spontaneous circulation (ROSC) or until CPR efforts are ceased.

3. Nonshockable rhythms: asystole and PEA
   a. After beginning CPR, attaching the monitor, and determining the rhythm establish an IV or IO access if not previously done.
   b. Prepare to administer epinephrine 1 mg every 3 to 5 minutes as prescribed.
   c. An advanced airway should be considered and capnography should be used to determine CPR quality.
   d. Continue CPR, analyze the rhythm, and follow the shockable rhythm approach if the rhythm becomes shockable.
   e. Consider reversible causes, which include hypoxia, hypovolemia, hydrogen ions or acidosis, hyperkalemia or hypokalemia (5 Hs) and tension pneumothorax, tamponade, toxins, thrombosis (pulmonary embolus), or thrombosis (acute coronary syndrome; 5 Ts).
f. Continue to cycle through the above steps until return of spontaneous circulation (ROSC) or until CPR efforts are ceased.

4. Postcardiac arrest care

a. If ROSC is achieved, advanced airway placement should be done if not previously established, oxygen saturation should be maintained greater than 94%, and hyperventilation should be avoided.

b. If hypotension is present (systolic blood pressure less than 90 mm Hg), vasopressors and IV fluid boluses are needed.

c. IV fluids include 1 to 2 liters of normal saline or lactated Ringer’s solution.

d. Vasopressors include epinephrine IV infusion 0.1 to 0.5 mg/kg/minute, dopamine IV infusion 5 to 10 mcg/kg/minute, or norepinephrine 0.1 to 0.5 mcg/kg/minute.

e. A 12-lead electrocardiogram should be done.

f. If the client is following commands, consider targeted temperature management to preserve neurological function, and IV fluids cooled to 4°C should be used.

g. If ST-elevation myocardial infarction (STEMI) or other form of acute MI are suspected, coronary reperfusion should be done, and the client should be managed on the critical care unit.

I. Cardiac tamponade

1. A pericardial effusion occurs when the space between the parietal and visceral layers of the pericardium fills with fluid.

2. Pericardial effusion places the client at risk for cardiac
tamponade, an accumulation of fluid in the pericardial cavity.

3. Tamponade restricts ventricular filling, and cardiac output drops.

4. Assessment
   a. Pulsus paradoxus
   b. Increased CVP
   c. Jugular venous distention with clear lungs
   d. Distant, muffled heart sounds
   e. Decreased cardiac output
   f. Narrowing pulse pressure

5. Interventions
   a. The client needs to be placed in a critical care unit for hemodynamic monitoring.
   b. Administer fluids intravenously as prescribed to manage decreased cardiac output.
   c. Prepare the client for chest x-ray or echocardiography.
   d. Prepare the client for pericardiocentesis to withdraw pericardial fluid if prescribed.
   e. Monitor for recurrence of tamponade following pericardiocentesis.
   f. If the client experiences recurrent tamponade or recurrent effusions or develops adhesions from chronic pericarditis, a portion (pericardial window) or all of the pericardium (pericardiectomy) may be removed to allow adequate ventricular filling and contraction.

F. Coronary artery bypass grafting
   1. The occluded coronary arteries are bypassed with the client’s own venous or arterial blood vessels.
   2. The saphenous vein, internal mammary artery, or other arteries may be used to bypass lesions in the coronary arteries.
   3. Coronary artery bypass grafting is performed when
the client does not respond to medical management of coronary artery disease or when vessels are severely occluded.

4. A minimally invasive direct coronary artery bypass (MIDCAB) may be an option for some clients who have a lesion in the LAD artery; a sternal incision is not required (usually a 2-inch [5 cm] left thoracotomy incision is done), and cardiopulmonary bypass is not required in this procedure.

5. Preoperative interventions
   a. Familiarize the client and family with the cardiac surgical critical care unit.
   b. Inform the client to expect a sternal incision, possible arm or leg incision(s), 1 or 2 chest tubes, a Foley catheter, and several IV fluid catheters.
   c. Inform the client that an endotracheal tube will be in place for a short period of time and that she or he will be unable to speak.
   d. Advise the client that she or he will be on mechanical ventilation and to breathe with the ventilator and not fight it.
   e. Instruct the client that postoperative pain is expected and that pain medication will be available.
   f. Instruct the client in how to splint the chest incision, cough and deep-breathe, use the incentive spirometer, and perform arm and leg exercises.
   g. Encourage the client and family to discuss anxieties and fears related to surgery.
   h. Note that prescribed medications may be discontinued preoperatively (usually, diuretics 2 to 3 days before surgery, digoxin 12 hours before surgery, and aspirin and anticoagulants 1 week before surgery).
   i. Administer medications as prescribed, which may include potassium chloride, antihypertensives, antidysrhythmics, and antibiotics.

6. Cardiac surgical unit postoperative interventions
   a. Mechanical ventilation is maintained
for 6 to 24 hours as prescribed.
b. The heart rate and rhythm, pulmonary artery and arterial pressures, urinary output, and neurological status are monitored closely.
c. Mediastinal and pleural chest tubes to the water seal drainage system with prescribed suction are present; drainage exceeding 100 to 150 mL/hr is reported to the surgeon.
d. Epicardial pacing wires are covered with sterile caps or connected to a temporary pacemaker generator; all equipment in use must be properly grounded to prevent microshock.
e. Fluid and electrolyte balance is monitored closely; fluids are usually restricted to 1500 to 2000 mL because the client usually has edema.
f. The blood pressure is monitored closely, because hypotension can cause collapse of a vein graft; hypertension can cause increased pressure, promoting leakage from the suture line, causing bleeding.
g. Temperature is monitored, and rewarming procedures are initiated using warm or thermal blankets if the temperature drops below 96.8°F (36.0°C); rewarm the client no faster than 1.8 degrees/hr to prevent shivering, and discontinue rewarming procedures when the temperature approaches 98.6°F (37.0°C).
h. Potassium is administered intravenously as prescribed to maintain the potassium level between 4 and 5 mEq/L (4 to 5 mmol/L) to prevent dysrhythmias.
i. The client is monitored for signs of cardiac tamponade, which will include sudden cessation of previously heavy mediastinal drainage, jugular vein distention with clear lung sounds, equalization of right atrial (RA) pressure and pulmonary artery wedge pressure, and pulsus paradoxus (see Section X. I.).
j. Pain is monitored, differentiating sternotomy pain from anginal pain, which would indicate graft failure.

7. Alarm safety and alarm fatigue: Refer to Section IX, C, 14.

8. Transfer of the client from the cardiac surgical unit

a. Monitor vital signs, level of consciousness, and peripheral perfusion.
b. Monitor for dysrhythmias.
c. Auscultate lungs and assess respiratory status.
d. Encourage the client to splint the incision, cough, deep-breathe, and use the incentive spirometer to raise secretions and prevent atelectasis.
e. Monitor temperature and white blood cell count, which, if elevated after 3 to 4 days, indicate infection.
f. Provide adequate fluids and hydration as prescribed to liquefy secretions.
g. Assess suture line and chest tube insertion sites for redness, purulent discharge, and signs of infection.
h. Assess sternal suture line for instability, which may indicate infection.
i. Guide the client to gradually resume activity.
j. Assess the client for tachycardia, postural (orthostatic) hypotension, and fatigue before, during, and after activity.
k. Discontinue activities if the BP drops more than 10 to 20 mm Hg or if the pulse increases more than 10 beats per minute.
l. Monitor episodes of pain closely.
m. See Box 69-16 for home care instructions.

XI. Complex Renal and Urinary Problems

A. Urosepsis

1. Urosepsis is a gram-negative bacteremia originating in the urinary tract.
2. The most common causative organism is Escherichia coli.
3. In a client who is immunocompromised, a common cause is infection from an indwelling urinary catheter or an untreated urinary tract infection (UTI).
4. The major problem is the ability of this bacterium to develop resistant strains.
5. Urosepsis can lead to septic shock if not treated aggressively.
6. Assessment: Fever is the most common and earliest manifestation.

7. Interventions
   a. Obtain a urine specimen for urine culture and sensitivity before administering antibiotics.
   b. Administer antibiotics intravenously as prescribed, usually until the client has been afebrile for 3 to 5 days.
   c. Switch to oral antibiotics as prescribed after the 3- to 5-day afebrile period.

B. Continuous renal replacement therapy
   1. Continuous renal replacement therapy (CRRT) provides continuous ultrafiltration of extracellular fluid and clearance of urinary toxins over a period of 8 to 24 hours; used primarily for clients in acute kidney injury (AKI) or critically ill clients with chronic kidney disease (CKD) who cannot tolerate hemodialysis.
   2. Water, electrolytes, and other solutes are removed as the client’s blood passes through a hemofilter.
   3. Because rapid shifts in fluids and electrolytes typically do not occur, hemofiltration is usually better tolerated by critically ill clients.
   4. There are 5 variations of CRRT (Box 69-17), some that require a hemodialysis machine and others that rely on the client’s BP to power the system.
   5. If CRRT does not require a hemodialysis machine, the client’s mean arterial BP needs to be maintained above 60 mm Hg, and arterial and venous access sites are necessary.

XII. Complex Neurological Problems

A. Traumatic head injury
   1. Head injury is trauma to the skull, resulting in mild to extensive damage to the brain.
   2. Immediate complications include cerebral bleeding,
hematomas, uncontrolled increased ICP, infections, and seizures.

3. Changes in personality or behavior, cranial nerve deficits, and any other residual deficits depend on the area of the brain damage and the extent of the damage.

B. Types of head injuries (Box 69-18)

1. Open
   a. Scalp lacerations
   b. Fractures in the skull
   c. Interruption of the dura mater

2. Closed
   a. Concussions
   b. Contusions
   c. Fractures

C. Hematoma

1. A collection of blood in the tissues that can occur as a result of a subarachnoid hemorrhage or an intracerebral hemorrhage.

2. Assessment
   a. Assessment findings depend on the injury.
   b. Clinical manifestations usually result from increased ICP.
   c. Changing neurological signs in the client
   d. Changes in level of consciousness
   e. Airway and breathing pattern changes
   f. Vital signs change, reflecting increased ICP (rise in blood pressure with widening pulse pressure; slowing of pulse)
   g. Headache, nausea, and vomiting
   h. Visual disturbances, pupillary changes, and papilledema
   i. **Nuchal rigidity** (not tested until spinal cord injury is ruled out)
   j. Cerebrospinal fluid (CSF) drainage from the ears or nose
   k. Weakness and paralysis
   l. Posturing
   m. Decreased sensation or absence of feeling
   n. Reflex activity changes
   o. Seizure activity
CSF can be distinguished from other fluids by the presence of concentric rings (bloody fluid surrounded by yellowish stain; halo sign) when the fluid is placed on a white sterile background, such as a gauze pad. CSF also tests positive for glucose when tested using a strip test.

3. Interventions

a. Monitor respiratory status and maintain a patent airway, because increased carbon dioxide (CO₂) levels increase cerebral edema.
b. Monitor neurological status and vital signs, including temperature.
c. Monitor for increased ICP.
d. Maintain head elevation to reduce venous pressure.
e. Prevent neck flexion.
f. Initiate normothermia measures for increased temperature.
g. Assess cranial nerve function, reflexes, and motor and sensory function.
h. Initiate seizure precautions.
i. Monitor for pain and restlessness.
j. Morphine sulfate or opioid medication may be prescribed to decrease agitation and control restlessness caused by pain for the head-injured client on a ventilator; administer with caution because it is a respiratory depressant and may increase ICP.
k. Monitor for drainage from the nose or ears, because this fluid may be CSF.

l. Do not attempt to clean the nose or suction if drainage occurs; client needs to avoid blowing her or his nose.
m. Do not clean the ear if drainage is noted, but apply a loose, dry sterile dressing.
n. Check drainage for the presence of CSF.
o. Notify the PHCP if drainage
from the ears or nose is noted and if the drainage tests positive for CSF.
p. Instruct the client to avoid coughing, because this increases ICP.
q. Monitor for signs of infection.
r. Prevent complications of immobility.
s. Inform the client and family about the possible behavior changes that may occur, including those that are expected and those that need to be reported.

D. Craniotomy
1. Surgical procedure that involves an incision through the cranium to remove accumulated blood or a tumor
2. Complications of the procedure include increased ICP from cerebral edema, hemorrhage, or obstruction of the normal flow of CSF.
3. Additional complications include hematomas, hypovolemic shock, hydrocephalus, respiratory and neurogenic complications, pulmonary edema, and wound infections.
4. Complications related to fluid and electrolyte imbalances include diabetes insipidus and inappropriate secretion of antidiuretic hormone.
5. Stereotactic radiosurgery (SRS) may be an alternative to traditional surgery and is usually used to treat tumors and arteriovenous malformations.
6. Preoperative interventions
   a. Explain the procedure to the client and family.
   b. Prepare to shave the client’s head as prescribed (usually done in the operating room) and cover the head with an appropriate covering.
   c. Stabilize the client before surgery.
7. Postoperative interventions (Box 69-19)
8. Postoperative positioning (Box 69-20)

E. Increased ICP
1. Increased ICP may be caused by trauma, hemorrhage, growths or tumors, hydrocephalus, edema, or inflammation.
2. Increased ICP can impede circulation to the brain, impede the absorption of CSF, affect the functioning of nerve cells, and lead to brainstem compression and
3. Assessment

   a. Altered level of consciousness, which is the most sensitive and earliest indication of increasing ICP
   b. Headache
   c. Abnormal respirations
   d. Rise in blood pressure with widening pulse pressure
   e. Slowing of pulse
   f. Elevated temperature
   g. Vomiting
   h. Pupil changes

4. Late signs of increased ICP include increased systolic blood pressure, widened pulse pressure, and slowed heart rate.

5. Other late signs include changes in motor function from weakness to hemiplegia, a positive Babinski reflex, decorticate or decerebrate posturing, and seizures.

6. Interventions

   a. Monitor respiratory status and prevent hypoxia.
   b. Avoid the administration of morphine sulfate and other opioids that depress respirations to prevent the occurrence of hypoxia.
   c. Maintain mechanical ventilation as prescribed; maintaining the PaCO₂ at 30 to 35 mm Hg (30 to 35 mm Hg) will result in vasoconstriction of the cerebral blood vessels, decreased blood flow, and therefore decreased ICP.
   d. Maintain body temperature.
   e. Prevent shivering, which can increase ICP.
   f. Decrease environmental stimuli.
   g. Monitor electrolyte levels and acid–base balance.
   h. Monitor intake and output.
   i. Limit fluid intake to 1200 mL/day as prescribed.
   j. Instruct the client to avoid straining activities, such as coughing and...
sneezing.

k. Instruct the client to avoid Valsalva’s maneuver.

For the client with increased ICP, elevate the head of the bed 30 to 40 degrees, avoid the Trendelenburg’s position, and prevent flexion of the neck and hips.

7. Medications (Box 69-21)
8. Surgical intervention: Also see Chapter 38 for additional information on ventriculoperitoneal shunts (Box 69-22)

F. Spinal cord injury

1. Trauma to the spinal cord causes partial or complete disruption of the nerve tracts and neurons.
2. The injury can involve contusion, laceration, or compression of the cord.
3. Spinal cord edema develops; necrosis of the spinal cord can develop as a result of compromised capillary circulation and venous return.
4. Loss of motor function, sensation, reflex activity, and bowel and bladder control may result.
5. The most common causes include motor vehicle crashes, falls, sporting and industrial accidents, and gunshot or stab wounds.
6. Complications related to the injury include respiratory failure, autonomic dysreflexia, spinal shock, further cord damage, and death.
7. Most frequently involved vertebrae
   a. Cervical—C5, C6, and C7
   b. Thoracic—T12
   c. Lumbar—L1

G. Transection of the cord

1. Complete transection of the cord: The spinal cord is severed completely, with total loss of sensation, movement, and reflex activity below the level of injury.
2. Partial transection of the cord
   a. The spinal cord is damaged or severed partially.
   b. The symptoms depend on the extent and location of the damage.
   c. If the cord has not suffered irreparable damage, early treatment is needed to prevent partial damage from developing into total and permanent damage.
H. Spinal cord syndromes in partial transection or injury (Fig. 69-29)

1. Central cord syndrome
   a. Occurs from damage in the central portion of the spinal cord
   b. Loss of motor function is more pronounced in the upper extremities, and varying degrees and patterns of sensation remain intact.

2. Anterior cord syndrome
   a. Caused by damage to the anterior portion of the gray and white matter of the spinal cord
   b. Motor function, pain, and temperature sensation are lost below the level of injury; however, the sensations of position, vibration, and touch remain intact.

3. Posterior cord syndrome
   a. Caused by damage to the posterior portion of the gray and white matter of the spinal cord
   b. Motor function remains intact, but the client experiences a loss of vibratory sense, crude touch, and position sensation.

4. Brown-Séquard syndrome
   a. Results from penetrating injuries that cause hemisection of the spinal cord or injuries that affect half of the cord
   b. Motor function, vibration, proprioception, and deep touch sensations are lost on the same side of the body (ipsilateral) as the lesion or cord damage.
   c. On the opposite side of the body (contralateral) from the lesion or cord damage, the sensations of pain, temperature, and light touch are affected.

5. Conus medullaris syndrome
   a. Follows damage to the lumbar nerve roots and conus medullaris in the spinal cord
   b. The client experiences bowel and bladder areflexia and flaccid lower extremities.
   c. If damage is limited to the upper sacral segments of the spinal cord,
bulbospongious penile (erection) and micturition reflexes will remain.

6. Cauda equina syndrome
   a. Occurs from injury to the lumbosacral nerve roots below the conus medullaris
   b. The client experiences areflexia of the bowel, bladder, and lower reflexes.

I. Assessment of spinal cord injuries (Box 69-23)

1. Dependent on the level of the cord injury
2. Level of spinal cord injury: Lowest spinal cord segment with intact motor and sensory function
3. Respiratory status changes
4. Motor and sensory changes below the level of injury
5. Total sensory loss and motor paralysis below the level of injury
6. Loss of reflexes below the level of injury
7. Loss of bladder and bowel control
8. Urinary retention and bladder distention
9. Presence of sweat, which does not occur on paralyzed areas

J. Cervical injuries

1. Injury at C2 to C3 is usually fatal.
2. C4 is the major innervation to the diaphragm by the phrenic nerve.
3. Involvement above C4 causes respiratory difficulty and paralysis of all four extremities.
4. The client may have movement in the shoulder if the injury is at C5 through C8 and may also have decreased respiratory reserve.

K. Thoracic level injuries

1. Loss of movement of the chest, trunk, bowel, bladder, and legs may occur, depending on the level of injury.
2. Leg paralysis (paraplegia) may occur.
3. Autonomic dysreflexia with injuries above T6 and in cervical lesions may occur.
4. Visceral distention from noxious stimuli such as a distended bladder or an impacted rectum may cause reactions such as sweating, bradycardia, hypertension, nasal stuffiness, and goose flesh.

L. Lumbar and sacral level injuries

1. Loss of movement and sensation of the lower extremities may occur.
2. S2 and S3 center on micturition; therefore, below this
level, the bladder will contract but not empty (neurogenic bladder).

3. Injury above S2 in males allows them to have an erection, but they are unable to ejaculate because of sympathetic nerve damage.

4. Injury between S2 and S4 damages the sympathetic and parasympathetic response, preventing erection or ejaculation.

M. Emergency interventions

Always suspect spinal cord injury when trauma occurs until this injury is ruled out. Immobilize the client on a spinal backboard with the head in a neutral position to prevent an incomplete injury from becoming complete.

1. Emergency management is critical, because improper movement can cause further damage and loss of neurological function.

2. Assess the respiratory pattern and maintain a patent airway.

3. Prevent head flexion, rotation, or extension.

4. During immobilization, maintain traction and alignment on the head by placing hands on both sides of the head by the ears.

5. Maintain an extended position.

6. Logroll the client.

7. No part of the body should be twisted or turned, and the client is not allowed to assume a sitting position.

8. In the emergency department, a client who has sustained a cervical fracture should be placed immediately in skeletal traction via skull tongs or halo traction to immobilize the cervical spine and reduce the fracture and dislocation.

N. Interventions during hospitalization

1. Respiratory system

   a. Assess respiratory status, because paralysis of the intercostal and abdominal muscles occurs with C4 injuries.

   b. Monitor arterial blood gas levels and maintain mechanical ventilation if prescribed to prevent respiratory arrest, especially with cervical injuries.

   c. Encourage deep breathing and the use of an incentive spirometer.
d. Monitor for signs of infection, particularly pneumonia.

2. Cardiovascular system
   a. Monitor for cardiac dysrhythmias.
   b. Assess for signs of hemorrhage or bleeding around the fracture site.
   c. Assess for signs of shock, such as hypotension, tachycardia, and a weak and thready pulse.
   d. Assess the lower extremities for deep vein thrombosis.
   e. Measure circumferences of the calf and thigh to identify increases in size.
   f. Apply antiembolism stockings as prescribed; remove daily to assess skin integrity.
   g. Monitor for orthostatic hypotension when repositioning the client.

3. Neuromuscular system
   a. Assess neurological status.
   b. Assess motor and sensory status to determine the level of injury.
   c. Assess motor ability by testing the client’s ability to squeeze hands, spread the fingers, move the toes, and turn the feet.
   d. Assess absence of sensation, hyposensation, or hypersensation by pinching the skin or prickling it with a pin, starting at the shoulders and working down the extremities.
   e. Monitor for signs of autonomic dysreflexia and spinal shock.
   f. Immobilize the client to promote healing and prevent further injury.
   g. Assess pain.
   h. Initiate measures to reduce pain.
   i. Administer analgesics as prescribed.
   j. Monitor for complications of immobility.
   k. Prepare the client for decompression laminectomy, spinal fusion, or insertion of instrumentation or rods if prescribed.
   l. Collaborate with the physical therapist and occupational therapist to determine appropriate exercise techniques, assess the need for hand
and wrist splints, and develop an appropriate plan to prevent footdrop.

4. Gastrointestinal system
   a. Assess abdomen for distention and hemorrhage.
   b. Monitor bowel sounds and assess for paralytic ileus.
   c. Prevent bowel retention.
   d. Initiate a bowel control program as appropriate.
   e. Maintain adequate nutrition and a high-fiber diet.

5. Renal system
   a. Prevent urinary retention.
   b. Initiate a bladder control program as appropriate.
   c. Maintain fluid and electrolyte balance.
   d. Maintain adequate fluid intake of 2000 mL/day unless contraindicated.
   e. Monitor for urinary tract infection and calculi.

6. Integumentary system
   a. Assess skin integrity.
   b. Ensure linens under the client are wrinkle-free.
   c. Turn the client every 2 hours.

7. Psychosocial integrity
   a. Assess psychosocial status.
   b. Encourage the client to express feelings of anger, depression, and loss.
   c. Discuss the sexual concerns of the client.
   d. Promote rehabilitation with self-care measures, setting realistic goals based on the client’s potential functional level.
   e. Encourage contact with appropriate community resources.

O. Spinal and neurogenic shock
1. **Spinal shock**: A complete but temporary loss of motor, sensory, reflex, and autonomic function that occurs immediately after injury as the cord’s response to the injury. It usually lasts less than 48 hours but can continue for several weeks.

2. **Neurogenic shock**: Occurs most commonly in clients with injuries above T6 and usually is experienced soon after the injury. Massive vasodilation occurs, leading to pooling of the blood in blood vessels, tissue...
hypoperfusion, and impaired cellular metabolism.

3. Assessment (see Box 69-23)

4. Interventions
   a. Monitor for signs of shock following a spinal cord injury.
   b. Monitor for hypotension and bradycardia.
   c. Monitor for reflex activity.
   d. Assess bowel sounds.
   e. Monitor for bowel and urinary retention.
   f. Provide supportive measures as prescribed, based on the presence of symptoms.
   g. Monitor for the return of reflexes.

P. Autonomic dysreflexia
   1. Also known as autonomic hyper-reflexia
   2. It generally occurs after the period of spinal shock is resolved and occurs with lesions or injuries above T6 and in cervical lesions or injuries.
   3. It is commonly caused by visceral distention from a distended bladder or impacted rectum.
   4. It is a neurological emergency and must be treated immediately to prevent a hypertensive stroke.
   5. Assessment (see Box 69-23)
   6. Interventions (see Priority Nursing Actions)

Priority Nursing Actions

Autonomic Dysreflexia in a Spinal Cord Injury Client
   1. Raise the head of the bed and ask that the primary health care provider (PHCP) be notified.
   2. Loosen tight clothing on the client.
   3. Check for bladder distention or other noxious stimulus.
   4. Administer an antihypertensive medication.
   5. Document the occurrence, treatment, and response.

Reference

Q. Cervical spine traction for cervical injuries
   1. Skeletal traction is used to stabilize fractures or
dislocations of the cervical or upper thoracic spine.

2. Two types of equipment used for cervical traction are skull (cervical) tongs and halo traction (halo fixation device).

3. Skull tongs
   a. Skull tongs are inserted into the outer aspect of the client’s skull, and traction is applied.
   b. Weights are attached to the tongs, and the client is used as countertraction. The nurse should not add or remove weights.
   c. Determine the amount of weight prescribed to be added to the traction.
   d. Ensure that weights hang securely and freely at all times.
   e. Ensure that the ropes for the traction remain within the pulley.
   f. Maintain body alignment and maintain care of the client on a special bed (such as a RotoRest bed or Stryker or Foster frame) as prescribed.
   g. Turn the client every 2 hours.
   h. Assess the insertion site of the tongs for infection.
   i. Provide sterile pin site care as prescribed.

4. Halo traction
   a. Halo traction is a static traction device that consists of a headpiece with 4 pins, 2 anterior and 2 posterior, inserted into the client’s skull.
   b. The metal halo ring may be attached to a vest (jacket) or cast when the spine is stable, allowing increased client mobility.
   c. Monitor the client’s neurological status for changes in movement or decreased strength.
   d. Never move or turn the client by holding or pulling on the halo traction device.
   e. Assess for tightness of the jacket by ensuring that 1 finger can be placed under the jacket.
f. Assess skin integrity to ensure that the jacket or cast is not causing pressure.
g. Provide sterile pin site care as prescribed.

5. Client education for halo traction device (Box 69-24)
   a. Initiate interventions in support of the client’s self-image.
   b. Teach the client and family pin care, care of the vest, and signs and symptoms of infection to report to her or his PHCP.

R. Interventions for thoracic, lumbar, and sacral injuries
   1. Bed rest
   2. Immobilization with a body cast if prescribed
   3. Assess for respiratory impairment and paralytic ileus, possible complications of the body cast.
   4. Use of a brace or corset when the client is out of bed

S. Surgical interventions for thoracic, lumbar, and sacral injuries
   1. Decompressive laminectomy
      a. Removal of 1 or more laminae
      b. Allows for cord expansion from edema; performed if conventional methods fail to prevent neurological deterioration
   2. Spinal fusion
      a. Spinal fusion is used for thoracic spinal injuries.
      b. Bone is grafted between the vertebrae for support and to strengthen the back.
   3. Postoperative interventions
      a. Monitor for respiratory impairment.
      b. Monitor vital signs, motor function, sensation, and circulatory status in the lower extremities.
      c. Encourage breathing exercises.
      d. Assess for signs of fluid and electrolyte imbalances.
      e. Observe for complications of immobility.
      f. Keep the client in a flat position as prescribed.
      g. Provide cast care if the client is in a full body cast.
h. Turn and reposition frequently by logrolling side to back to side, using turning sheets and pillows between the legs to maintain alignment.

i. Administer pain medication as prescribed.

j. Maintain on NPO status until the client is passing flatus.

k. Monitor bowel sounds.

l. Provide the use of a fracture bedpan.

m. Monitor intake and output.

n. Maintain nutritional status.

T. Medications

1. Dexamethasone: Used for its antiinflammatory and edema-reducing effects; may interfere with healing because it suppresses the immune system

2. Dextran: Plasma expander used to increase capillary blood flow within the spinal cord and to prevent or treat hypotension

3. Baclofen: Used for clients with upper motor neuron injuries to control muscle spasticity

U. Management of sedation, agitation, and delirium

1. The Society of Critical Care Medicine (SCCM) developed guidelines for managing sedation, agitation, and delirium in critically ill clients.

   a. These guidelines recommend using a standardized tool such as the Richmond Agitation-Sedation Scale (RASS) (Box 69-25) to titrate sedation medications, because not all individuals metabolize these medications at the same rate (Box 69-26).

   b. Ruling out pain as a cause of agitation is an important consideration in deciding how to titrate sedation medications.

2. Sedation

   a. Sedation is classified as light, moderate, deep, and general anesthesia (see Box 69-26).

   b. Pharmacological sedation includes use of benzodiazepines (diazepam, lorazepam, midazolam), sedative-hypnotics (propofol), and centrally
acting alpha-adrenergic agonists (dexmedetomidine).

3. Propofol
   a. Propofol is contained in glass and is a white milky substance. It is a lipid emulsion substance with a short half-life that can be easily titrated because it is rapidly eliminated from the body, within 30 minutes.
   b. Opiates should be added for pain control and amnesic effects, because propofol does not produce amnesia.
   c. Propofol-related infusion syndrome causing metabolic acidosis, muscular weakness, rhabdomyolysis, myoglobinuria, acute kidney injury, and cardiac dysrhythmias has been known to occur.
   d. Propofol is conducive to bacterial growth; therefore, infusion sets should be changed every 6 to 12 hours.

4. Dexmedetomidine
   a. Dexmedetomidine is used as a short-term sedative (24 hours or less) in mechanically ventilated clients.
   b. This medication causes sedation and analgesic effects and allows for clients to be minimally interactive while sedated. It can still be used even after extubation to help with anxiety related to weaning.
   c. It is eliminated from the body within 2 hours, or dramatically longer in the case of liver failure.

5. Agitation
   a. A hyperactive state that results in movements ranging from slight restlessness to pulling out lines or tubes or physical aggression.
   b. Common causes include pain, anxiety, delirium, hypoxia, ventilator dyssynchrony, neurological injury, uncomfortable position, full bladder, sleep deprivation, alcohol withdrawal, sepsis, medication reaction, and organ failure.
   c. Assessed using RASS, and the goal is to treat the cause rather than
overmedicate.
d. Haloperidol rather than benzodiazepines should be used to manage acute agitation; benzodiazepines can cause delirium.
e. If the client is at risk for harming themselves or others, a benzodiazepine may be prescribed.

6. Delirium

a. Global impairment of cognitive processes with a sudden onset, associated with disorientation, impaired short-term memory, hallucinations or other altered sensory patterns, abnormal thought processes, and inappropriate behavior.
b. Common causes include acute brain dysfunction, sepsis, critical illness, or overall dysfunction of vital organs.
c. Differentiating between agitation and delirium can be difficult but is important in targeting the cause and implementing an appropriate treatment approach.
d. Standardized assessment tools are available that can be used in tandem with RASS; one tool is the Confusion Assessment Method for the Intensive Care Unit (CAM-ICU).
e. Haloperidol or atypical antipsychotics can be used for hyperactive delirium.
f. Preventive measures for delirium include spontaneous awakening for sedated clients, daily delirium monitoring using a standardized tool, mobility, and initiation of sleep protocols where nursing care is clustered to provide uninterrupted rest periods.

XIII. Complex Immune Problems

A. Anaphylaxis

1. A serious and immediate hypersensitivity reaction that releases histamine from the damaged cells
2. Anaphylaxis can be systemic or cutaneous (localized).
3. Assessment (Fig. 69-30)
4. Interventions (see Priority Nursing Actions)
Priority Nursing Actions

Anaphylactic Reaction

1. Quickly assess respiratory status and maintain a patent airway.
2. Call the primary health care provider (PHCP) and Rapid Response Team.
3. Administer oxygen.
4. Start an intravenous (IV) line and infuse normal saline.
5. Prepare to administer diphenhydramine and epinephrine, and possibly corticosteroids.
6. Document the event, actions taken, and the client’s response.

Reference

XIV. Shock and Sepsis

A. Shock

1. Four main types of shock: hypovolemic, cardiogenic, vasogenic (distributive), obstructive
   a. Hypovolemic shock: The most common type, defined as a shock state caused by internal or external blood or fluid loss
   b. Cardiogenic shock: Caused by heart (pump) failure resulting in diminished cardiac output
   c. Vasogenic shock: With this type, the vasculature is dilated, making it difficult for the heart to move blood and fluid to the rest of the body; types include septic shock, anaphylactic shock, and neurogenic shock.
   d. Obstructive shock: A type of shock that is caused by a physical obstruction that reduces the filling or outflow of blood from the heart that results in a reduced cardiac output. Conditions that can contribute to this type of shock include cardiac tamponade, tension pneumothorax, superior vena cava syndrome, abdominal compartment syndrome, and pulmonary embolism.

2. Causes of vasodilation
   a. Septic shock: Massive infection leads to sepsis as a result of the release of endotoxins from bacteria; this causes vasodilation and pooling of blood.
b. Anaphylactic shock: An allergic reaction to substances like drugs, food, and insect bites leads to anaphylactic shock, which results in an acute and life-threatening hypersensitivity reaction. This immediate reaction causes massive vasodilation, release of vasoactive mediators, and an increase in capillary permeability.

c. Neurogenic shock: A phenomenon that occurs after spinal cord injury. The injury results in massive vasodilation without compensation as a consequence of the loss of spinal nervous system vasoconstrictor tone; this leads to a pooling of blood in the blood vessels.

3. Hemodynamic monitoring is important for assessing a client in any type of shock state and includes:
   a. Cardiac output: Reflects blood flow reaching the tissue. Normal cardiac output is 4 to 6 liters per minute.
   b. Mean arterial pressure: Amount of pressure the blood is placing on the walls of the vessels as the blood leaves the heart. Normal mean arterial pressure is between 70 mm Hg and 105 mm Hg. This measure is an important indicator of adequacy of cardiac output. Mean arterial pressure greater than 60 mm Hg is needed to maintain perfusion to vital organs.
   c. Central venous pressure: A measure of pressure in terms of right ventricular preload; measures the pressure of the blood returning from the body to the heart. The normal central venous pressure is 3 to 8 mm Hg. An elevated central venous pressure indicates right ventricular failure and volume overload. A low central venous pressure indicates hypovolemia.
   d. Cerebral perfusion pressure: A measure of perfusion to the brain, calculated by subtracting the ICP from the mean arterial pressure. The normal cerebral perfusion pressure is 70 to 100 mm Hg. A central perfusion pressure less than
50 mm Hg is associated with ischemia and tissue death. A central perfusion pressure less than 30 mm Hg is incompatible with life.

4. Stages of shock
   a. Stage 1 Initial: restlessness, increased heart rate, cool and pale skin, agitation
   b. Stage 2 Compensatory: cardiac output is less than 4 to 6 liters per minute, systolic blood pressure is less than 100 mm Hg, there is decreased urinary output, confusion, and the cerebral perfusion pressure is less than 70 mm Hg.
   c. Stage 3 Progressive: edema, excessively low blood pressure, dysrhythmias, weak and thready pulses
   d. Stage 4: This stage is unresponsive to vasopressors, there is profound hypotension, the heart rate slows, and multiple organ failure ensues. Most often, the client will not survive.

   It is a priority to intervene in the early stages of shock to prevent progression to the later stages.

5. Treatments for shock
   a. Treatment depends on the cause of the shock and the type of shock.
   b. For clients in shock, central venous and pulmonary artery catheters are inserted to monitor hemodynamic status.
   c. Assessment of the central venous pressure, urine output, heart rate, and clinical and mental status is done every 5 to 15 minutes.
   d. Oxygen is administered to assist in tissue perfusion.
   e. Isotonic and electrolyte intravenous solutions such as lactated Ringer’s solution and normal saline are frequently used.
   f. Rapid infusion of volume-expanding fluids including whole blood, plasma, and plasma substitutes such as colloid fluids
g. Whole blood is effective but is not used often as a treatment measure because of the risk of transfusion reactions.
h. Administration of medications is withheld until circulating volume has been restored.
i. The primary goal for medication therapy with shock is to improve tissue perfusion.
j. Medications used to improve perfusion in shock are administered intravenously via an infusion pump and often via a central line.
k. It is important to note that if the shock state is cardiogenic in nature, the infusion of volume-expanding fluids may result in pulmonary edema; therefore, restoration of cardiac function is the priority for this type of shock. Cardiotonic medications such as digoxin, dopamine, or norepinephrine may be administered to increase cardiac contractility and induce vasoconstriction.
l. Once improvement of perfusion is achieved, interventions are then directed toward the underlying cause of the condition.

B. Sepsis

1. A group of symptoms or syndrome in response to an infection that can include organ dysfunction related to the infection.
2. The main causative organisms are gram-negative and gram-positive bacteria; however, sepsis can also result from viral, fungal, and parasitic infections.
3. Sepsis diagnostic criteria (Box 69-27)

C. Septic shock

1. Signs and symptoms include persistent hypotension despite adequate fluid resuscitation requiring vasopressors, along with decreased tissue perfusion that progresses to tissue hypoxia.
2. In both sepsis and septic shock, the body’s immune response to an invading microorganism is exaggerated, resulting in the activation of proinflammatory and antiinflammatory responses and coagulation abnormalities.
   a. Increased coagulation and decreased
fibrinolysis results in platelet and neutrophil aggregation with adherence to endothelium, and endothelial damage related to the formation of microthrombi in the microvasculature.

b. Endotoxins released from the invading organism’s cell wall result in release of the body’s cytokines (such as tumor necrosis factor [TNF] and interleukin-1 [IL-1]), which cause vasodilation and increased capillary permeability, which contributes to hypotension.

3. Three major effects septic shock has on the body include vasodilation, maldistribution of blood flow, and myocardial depression.

   a. Vasodilation causes relative hypovolemia and hypotension in euvolemic clients.

   b. Decreased microcirculation causes tissue hypoxia.

   c. Perfusion is further impaired by a decrease in ejection fraction, in which the ventricles dilate to compensate.

   d. Clients who develop septic shock are at risk for the development of respiratory failure and acute respiratory distress syndrome.

4. Nursing interventions

   a. Fluid replacement: 30 to 50 mL/kg fluid resuscitation with isotonic crystalloids; albumin may also be administered.

   b. Vasopressor therapy to increase cardiac output.

   c. Intravenous corticosteroids may be administered in clients with inadequate blood pressure readings despite fluid resuscitation and vasopressor therapy.

   d. IV antibiotics should be started within the first hour of sepsis or septic shock; cultures should be obtained before the initiation of antibiotic therapy.

   e. Glucose levels should be maintained below 180 mg/dL (10.02 mmol/L).

   f. Administer stress ulcer prophylaxis and venous thromboembolism prophylaxis.

   g. Monitor level of consciousness,
cardiovascular status, pulse oximetry, rate and depth of respirations, urine output, bowel sounds, gastric secretions and stools for occult blood, and temperature and skin changes, because the client is at risk for skin breakdown due to decreased tissue perfusion.

D. Systemic Inflammatory Response Syndrome (SIRS)
1. Defined as a systemic inflammatory response that is characterized by generalized inflammation in organs separate from the initial affected area; it is a serious condition and may be caused by a severe bacterial infection (sepsis), trauma, or pancreatitis.
2. SIRS can also be triggered by a variety of different mechanisms: mechanical tissue trauma (burns, crush injuries, surgical procedures); abscess formation; ischemic or necrotic tissue; microbial invasion; endotoxin release from invading micro-organisms; global perfusion deficits including postcardiac resuscitation or states of shock; and regional perfusion deficits.

E. Multiple Organ Dysfunction Syndrome (MODS)
1. A complication of sepsis; the failure of two or more organ systems as a result of SIRS, in which homeostasis cannot be maintained without intervention.
2. Prognosis is poor once three or more organ systems fail.
3. Clinical manifestations and management of SIRS and MODS (Table 69-12).
4. Nursing interventions for SIRS and MODS include early identification of sepsis; preventing and treating infections; maintenance of tissue oxygenation; promoting nutrition to meet metabolic needs; and support of failing organ systems.

Box 69-1

Peripheral Intravenous Sites to Avoid

- Edematous extremity
- An arm that is weak, traumatized, or paralyzed
- The arm on the same side as a mastectomy
- An arm that has an arteriovenous fistula or shunt for dialysis
- A skin area that is infected

Table 69-2

Complications of Intravenous Therapy
<table>
<thead>
<tr>
<th>Complication</th>
<th>Description</th>
<th>Signs</th>
<th>Prevention and Interventions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Air embolism</td>
<td>A bolus of air enters the vein through an inadequately primed IV line, from a loose connection, during tubing change, or during removal of the IV.</td>
<td>Tachycardia, Chest pain and dyspnea, Hypotension, Cyanosis, Decreased level of consciousness</td>
<td>Prime tubing with fluid before use, and monitor for any air bubbles in the tubing. Secure all connections. Replace the IV fluid before the bag or bottle is empty. Monitor for signs of air embolism; if suspected, clamp the tubing, turn the client on the left side with the head of the bed lowered (Trendelenburg's position) to trap the air in the right atrium, and notify the PHCP.</td>
</tr>
<tr>
<td>Catheter embolism</td>
<td>An obstruction that results from breakage of the catheter tip during IV line insertion or removal</td>
<td>Decrease in blood pressure, Pain along the vein, Weak, rapid pulse, Cyanosis of the nailbeds, Loss of consciousness</td>
<td>Remove the catheter carefully. Inspect the catheter when removed. If the catheter tip has broken off, place a tourniquet as proximally as possible to the IV site on the affected limb, notify the PHCP immediately, prepare to obtain a radiograph, and prepare the client for surgery to remove the catheter piece(s), if necessary.</td>
</tr>
<tr>
<td>Circulatory overload</td>
<td>Also known as fluid overload; results from the administration of fluids too rapidly, especially in a client at risk for fluid overload.</td>
<td>Increased blood pressure, Distended jugular veins, Rapid breathing, Dyspnea, Moist cough and crackles</td>
<td>Identify clients at risk for circulatory overload. Calculate and monitor the drip rate frequently. Use an electronic IV infusion device and frequently check the drip rate or setting (at least every hour for an adult). If an electronic infusion device is not being used, add a time tape (label) to the IV bag or bottle next to the volume markings; mark on the tape the expected hourly decrease in volume based on the mL/hr calculation. Monitor for signs of circulatory overload. If circulatory overload occurs, decrease the flow rate to a minimum, at a keep-open rate; elevate the head of the bed; keep the client warm; assess lung sounds; assess for edema; and notify the PHCP.</td>
</tr>
<tr>
<td>Electrolyte overload and imbalance</td>
<td>An electrolyte overload leading to imbalance is caused by too rapid or excessive infusion or by use of an inappropriate IV solution.</td>
<td>Signs depend on the specific electrolyte imbalance.</td>
<td>Assess laboratory value reports. Verify the correct solution. Calculate and monitor the flow rate. Use an electronic IV infusion device and frequently check the drip rate or setting (at least every hour for an adult). Use a time tape label if an electronic infusion device is not being used. Per agency procedure, place a red medication sticker on the bag or bottle if a medication has been added to the IV solution. Monitor for signs of an electrolyte imbalance and notify the PHCP if they occur.</td>
</tr>
<tr>
<td>Complication</td>
<td>Description</td>
<td>Signs</td>
<td>Prevention and Interventions</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------</td>
<td>-------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>Hematoma</td>
<td>The collection of blood in the tissues after an unsuccessful venipuncture or after the venipuncture site is discontinued and blood continues to ooze into the tissue</td>
<td>Ecchymosis, immediate swelling and leakage of blood at the site, and hard and painful lumps at the site</td>
<td>When starting an IV, avoid piercing the posterior wall of the vein. Do not apply a tourniquet to the extremity immediately after an unsuccessful venipuncture. When discontinuing an IV, apply pressure to the site for 2-3 minutes and elevate the extremity; apply pressure longer for clients with a bleeding disorder or who are taking anticoagulants. If a hematoma develops, elevate the extremity and apply pressure and ice as prescribed. Document accordingly, including taking pictures of the IV site if indicated by agency policy.</td>
</tr>
<tr>
<td>Infection</td>
<td>Infection occurs from the entry of microorganisms into the body through the venipuncture site. Venipuncture interrupts the integrity of the skin, the first line of defense against infection. The longer the therapy continues, the greater the risk for infection. Infection can occur locally at the IV insertion site or systemically from the entry of microorganisms into the body. At-risk clients: Immunocompromised clients with diseases such as cancer, human immunodeficiency virus or acquired immunodeficiency syndrome, those receiving biological modifier response medications for treatment of autoimmune conditions, or status post organ transplant are at risk for infection. Clients receiving treatments such as chemotherapy who have an altered or lowered white blood cell count are at risk for infection. Older clients, because aging alters the effectiveness of the immune system, are at risk for infection. Clients with diabetes mellitus are at risk for infection.</td>
<td>Local—redness, swelling, and drainage at the site. Systemic—chills, fever, malaise, headache, nausea, vomiting, backache, tachycardia</td>
<td>Assess the client for predisposition to or risk for infection. Maintain strict asepsis when caring for the IV site. Monitor for signs of local or systemic infection. Monitor white blood cell counts. Check fluid containers for cracks, leaks, cloudiness, or other evidence of contamination. Change IV tubing every 96 hours in accordance with CDC recommendations or according to agency policy; change IV site dressing when soiled or contaminated and according to agency policy. Label the IV site, bag or bottle, and tubing with the date and time to ensure these are changed on time according to agency policy. Ensure that the IV solution is not hanging for more than 24 hours. If infection occurs, the PHCP is notified; discontinue the IV, and place the venipuncture device in a sterile container for possible culture. Prepare to obtain blood cultures as prescribed if infection occurs and document accordingly. Restart an IV in the opposite arm to differentiate sepsis (systemic infection) from local infection at the IV site. Document accordingly, including taking pictures of the IV site if indicated by agency policy.</td>

</table>
| Infiltration                 | - Infiltration is seepage of the IV fluid out of the vein and into the surrounding interstitial spaces.  
  - Infiltration occurs when an access device has become dislodged or perforates the wall of the vein or when venous backpressure occurs because of a clot or venous spasm. | - Edema, pain, numbness, and coolness at the site; may or may not have a blood return | - Avoid venipuncture over an area of flexion.  
  - Anchor the cannula and a loop of tubing securely with tape.  
  - Use an armboard or splint as needed if the client is restless or active.  
  - Monitor the IV rate for a decrease or a cessation of flow.  
  - Evaluate the IV site for infiltration by occluding the vein proximal to the IV site. If the IV fluid continues to flow, the cannula is probably outside the vein (infiltrated); if the IV flow stops after occlusion of the vein, the IV device is still in the vein.  
  - Insert the IV fluid container below the IV site, and monitor for the appearance of blood in the IV tubing; if blood appears, the IV device is most likely in the vein.  
  - If infiltration has occurred, remove the IV device immediately; elevate the extremity and apply compresses (warm or cool, depending on the IV solution that was infusing and the PHCP's prescription and agency procedure) over the affected area.  
  - Do not rub an infiltrated area, which can cause hematoma.  
  - Document accordingly, including taking pictures of the IV site if indicated by agency policy. |
| Phlebitis and Thrombophlebitis| - Phlebitis is an inflammation of the vein that can occur from mechanical or chemical (medication) trauma or from a local infection.  
  - Phlebitis can cause the development of a clot (thrombophlebitis). | - Phlebitis: Heat, redness, tenderness at the site; not swollen or hard; intravenous infusion sluggish  
  Thrombophlebitis: hard and cord-like vein; heat, redness, tenderness at site; intravenous infusion sluggish. | - Use an IV cannula smaller than the vein, and avoid using very small veins when administering irritating solutions.  
  - Avoid using the lower extremities (legs and feet) as an access area for the IV.  
  - Avoid venipuncture over an area of flexion.  
  - Anchor the cannula and a loop of tubing securely with tape.  
  - Use an armboard or splint as needed if the client is restless or active.  
  - Change the venipuncture site every 72-96 hours in accordance with CDC recommendations and agency policy.  
  - If phlebitis occurs, remove the IV device immediately and restart it in the opposite extremity; notify the PHCP if phlebitis is suspected, and apply warm, moist compresses, as prescribed.  
  - If thrombophlebitis occurs, do not irrigate the IV catheter; remove the IV, notify the PHCP, and restart the IV in the opposite extremity.  
  - Document accordingly, including taking pictures if indicated by agency policy. |

<tr>
<td>Air embolism</td>
<td>▪ Catheter system opened or IV tubing disconnected ▪ Air entry on IV tubing changes</td>
<td>▪ Apprehension ▪ Chest pain ▪ Dyspnea ▪ Hypotension ▪ Load churning sound heard over pericardium on auscultation ▪ Rapid and weak pulse ▪ Respiratory distress</td>
<td>▪ Clamp all ports of the IV catheter. ▪ Place the client in a left side-lying position with the head lower than the feet. ▪ Notify the PHCP. ▪ Administer oxygen.</td>
<td>▪ Make sure all catheter connections are secure (use tape per agency protocol). ▪ Clamp the catheter when not in use and when changing caps (follow agency protocol for flushing and clamping the catheter and cap changes). ▪ Instruct the client in the Valsalva maneuver for tubing and cap changes. ▪ For tubing and cap changes, place the client in the Trendelenburg's position (if not contraindicated) with the head turned in the opposite direction of the insertion site; client should hold breath and bear down.</td>
</tr>
<tr>
<td>Hyperglycemia</td>
<td>▪ High concentration of dextrose in solution ▪ Client receiving solution too quickly ▪ Not enough insulin ▪ Infection</td>
<td>▪ Restlessness ▪ Confusion ▪ Weakness ▪ Diaphoresis ▪ Elevated blood glucose level &gt; 200 mg/dL (11.1 mmol/L) ▪ Excessive thirst ▪ Fatigue ▪ Kussmaul respirations ▪ Coma (when severe)</td>
<td>▪ Notify the PHCP. ▪ The infusion rate may need to be slowed. ▪ Monitor blood glucose levels. ▪ Administer regular insulin as prescribed.</td>
<td>▪ Assess the client for a history of glucose intolerance. ▪ Assess the client's medication history (corticosteroids increase blood glucose). ▪ Begin infusion at a slow rate as prescribed (usually 40-60 mL/hr). ▪ Monitor blood glucose levels per agency protocol. ▪ Administer regular insulin as prescribed. ▪ Use strict aseptic technique to prevent infection.</td>
</tr>
<tr>
<td>Hypervolemic</td>
<td>▪ Excessive fluid administration or administration of fluid too rapidly ▪ Renal dysfunction ▪ Heart failure ▪ Hepatic failure</td>
<td>▪ Bounding pulse ▪ Crackles on lung auscultation ▪ Headache ▪ Increased blood pressure ▪ Jugular vein distention ▪ Weight gain greater than desired</td>
<td>▪ Slow or stop IV infusion. ▪ Notify the PHCP. ▪ Restrict fluids. ▪ Administer diuretics as prescribed. ▪ Use dialysis as prescribed (in extreme cases).</td>
<td>▪ Assess client's history for risk for hypervolemia. ▪ Administer via electronic infusion device and ensure proper function of the device. ▪ Never increase the rate of infusion of the device to &quot;catch up&quot; if the infusion gets behind. ▪ Monitor intake and output. ▪ Monitor weight daily (ideal weight gain is 1-2 lb per week).</td>
</tr>
<tr>
<td>Hypoglycemia</td>
<td>▪ PN abruptly discontinued ▪ Too much insulin being administered</td>
<td>▪ Anxiety ▪ Diaphoresis ▪ Hunger ▪ Low blood glucose level &lt; 70 mg/dL (&lt;3.9 mmol/L) ▪ Shakiness ▪ Weakness</td>
<td>▪ Notify the PHCP. ▪ Administer IV dextrose. ▪ Monitor blood glucose level.</td>
<td>▪ Gradually decrease PN solution when discontinued. ▪ Infuse 10% dextrose at same rate as the PN to prevent hypoglycemia for 1-2 hours after the PN solution is discontinued. ▪ Monitor glucose levels and check the level 1 hour after discontinuing the PN.</td>
</tr>
<tr>
<td>Infection</td>
<td>▪ Poor aseptic technique ▪ Catheter contamination ▪ Contamination of solution</td>
<td>▪ Chills ▪ Fever ▪ Elevated white blood cell count ▪ Redness or drainage at insertion site</td>
<td>▪ Notify the PHCP. ▪ Remove catheter. ▪ Send catheter tip to the laboratory for culture. ▪ Prepare to obtain blood cultures. ▪ Prepare for antibiotic administration.</td>
<td>▪ Use strict aseptic techniques (PN solution has a high concentration of glucose and is a medium for bacterial growth). ▪ Monitor temperature (fever could indicate infection). ▪ Assess IV site for signs of infection (redness, swelling, drainage). ▪ Change site dressing, solution, and tubing as specified by agency policy. ▪ Do not disconnect tubing unnecessarily.</td>
</tr>

Box 69-3

Home Care Instructions for Parenteral Nutrition Therapy

- Teach the client and caregiver how to obtain, administer, and maintain parenteral nutrition fluids.
- Teach the client and caregiver how to change a sterile dressing.
- Obtain a daily weight at the same time of day in the same clothes.
- Stress that if a weight gain of more than 3 lb/week is noted, this may indicate excessive fluid intake and should be reported.
- Monitor the blood glucose level and report abnormalities immediately. Teach the client how to monitor for and manage hypoglycemia and hyperglycemia.
- Teach the client and caregiver about the signs and symptoms of side effects or adverse effects such as infection, thrombosis, air embolism, and catheter displacement.
- Teach the client and caregiver the actions to take if a complication arises and about the importance of reporting complications to the primary health care provider.
- For signs and symptoms of thrombosis, the client should report edema of the arm or at the catheter insertion site, neck pain, and jugular vein distention.
- Leaking of fluid from the insertion site or pain or discomfort as the fluids are infused may indicate displacement of the catheter; this must be reported immediately.
- Encourage the client and caregiver to contact the primary health care provider if they have questions about administration or any other questions.
- Inform the client and caregiver about the importance of follow-up care.

PHCP, Primary Health care provider; IV, intravenous; PN, parenteral nutrition.

Adapted from Ignatavicius D, Workman M: Medical-surgical nursing: patient-centered collaborative care, ed 7, St. Louis, 2013, Saunders.
- Teach the client to keep electronic infusion devices fully charged in case of electrical power failure.

The ABO type of the donor should be compatible with the recipient’s. Type A can receive from type A or O; type B from type B or O; type AB can receive from type A, B, AB, or O; type O only from type O.

**Box 69-4**

**Precautions and Nursing Responsibilities for Blood Administration**

**General Precautions**

- A large volume of refrigerated blood infused rapidly through a central venous catheter into the ventricle of the heart can cause cardiac dysrhythmias.
- No solution other than normal saline should be added to blood components.
- Medications are never added to blood components or piggybacked into a blood transfusion.
- To avoid the risk of septicemia, infusions (1 unit) should not exceed the prescribed time for administration (2 to 4 hours for packed red blood cells); follow evidence-based practice guidelines and agency procedure.
- The blood administration set should be changed with each unit of blood, or according to agency policy, to reduce the risk of septicemia.
- Check the blood bag for the date of expiration; components expire at midnight on the day marked on the bag unless otherwise specified.
- Inspect the blood bag for leaks, abnormal color, clots, and bubbles.
- Blood must be administered as soon as possible (within 20 to 30 minutes) after being received from the blood bank, because this is the maximal allowable time out of monitored storage.
- Never refrigerate blood in refrigerators other than those used in blood banks; if the blood is not administered within 20 to 30 minutes, return it to the blood
The recommended rate of infusion varies with the blood component being transfused and depends on the client’s condition; generally, blood is infused as quickly as the client’s condition allows (always follow agency guidelines and prescriptions).

- Components containing few red blood cells (RBCs) and platelets may be infused rapidly, but caution should be taken to avoid circulatory overload.
- The nurse should measure vital signs and assess lung sounds before the transfusion and again after the first 15 minutes and every 30 minutes to 1 hour (per agency policy) until 1 hour after the transfusion is completed.

**Client Assessment**

- Assess for any cultural or religious beliefs regarding blood transfusions.
- A Jehovah’s Witness cannot receive blood or blood products; this group believes that receiving a blood transfusion has eternal consequences.
- Ensure that an informed consent has been obtained.
- Explain the procedure to the client and determine whether the client has ever received a blood transfusion or experienced any previous reactions to blood transfusions.
- Check the client’s vital signs; assess renal, circulatory, and respiratory status and the client’s ability to tolerate intravenously administered fluids.
- If the client’s temperature is elevated, notify the primary health care provider (PHCP) before beginning the transfusion; a fever may be a cause for delaying the transfusion in addition to masking a possible symptom of an acute transfusion reaction.

**Blood Bank Precautions**

- Blood will be released from the blood bank only to personnel specified by agency policy.
- The name and identification number of the intended recipient must be provided to the blood bank, and a documented permanent record of this information must be maintained.
- Blood should be transported from the blood bank to only 1 client at a time to prevent blood delivery to the wrong client.
- Only 1 unit of blood should be transported at a time, even if the client is prescribed to have more than 1 unit transfused.

**Client Identity and Compatibility**

- Check the PHCP’s prescription for the administration of the blood product.
- The most critical phase of the transfusion is confirming product compatibility and verifying client identity.
• Universal barcode systems for blood transfusions should be used to confirm product compatibility, client identity, and expiration (client identification requires 2 identifiers).

• Two licensed nurses (follow agency procedure) need to check the PHCP’s prescription, the client’s identity, and the client’s identification band or bracelet and number, verifying that the name and number are identical to those on the blood component tag.

• At the bedside, the nurse asks the client to state her or his name, and the nurse compares the name with the name on the identification band or bracelet.

• The nurse checks the blood bag tag, label, and blood requisition form to ensure that ABO and Rh types are compatible. The nurse uses the barcode scanning system per agency policy.

• If the nurse notes any inconsistencies when verifying client identity and compatibility, the nurse notifies the blood bank immediately.

**Administration of the Transfusion**

• Maintain standard and transmission-based precautions and surgical asepsis as necessary.

• Insert an intravenous (IV) line and infuse normal saline; maintain the infusion at a keep-vein-open rate.

• An 18- or 19-gauge IV needle will be needed to achieve a maximum flow rate of blood products and to prevent damage to RBCs; if a smaller-gauge needle must be used, RBCs may be diluted with normal saline (check agency procedure).

• A central venous catheter is an acceptable venous access option for blood transfusions; for a multilumen catheter, use the largest catheter port available or check the port size to ensure that it is adequate for blood administration.

• Always check the bag for the volume of the blood component.

• Blood products should be infused through administration sets designed specifically for blood; use a Y-tubing or straight-tubing blood administration set that contains a filter designed to trap fibrin clots and other debris that accumulate during blood storage.

• Premedicate the client with acetaminophen or diphenhydramine, as prescribed, if the client has a history of adverse reactions; if prescribed, oral medications should be administered 30 minutes before the transfusion is started, and intravenously administered medications may be given immediately before the transfusion is started.

• Instruct the client to report anything unusual immediately.

• Determine the rate of infusion by the PHCP’s prescription or, if not specified, by agency policy.

• Begin the transfusion slowly under close supervision; if no reaction is noted within the first 15 minutes, the flow can be increased to the prescribed rate.

• During the transfusion, monitor the client for signs and symptoms of a transfusion reaction; the first 15 minutes of the transfusion are the most critical, and the nurse must stay with the client.
If an ABO incompatibility exists or a severe allergic reaction occurs, the reaction is usually evident within the first 50 mL of the transfusion.

Document the client’s tolerance to the administration of the blood product.

Monitor appropriate laboratory values and document effectiveness of treatment related to the specific type of blood product.

Reactions to the Transfusion

If a transfusion reaction occurs, stop the transfusion, change the IV tubing down to the IV site, keep the IV line open with normal saline, notify the PHCP and blood bank, and return the blood bag and tubing to the blood bank.

Do not leave the client alone, and monitor the client’s vital signs and monitor for any life-threatening signs or symptoms.

Obtain appropriate laboratory samples, such as blood and urine samples (free hemoglobin indicates that RBCs were hemolyzed), according to agency procedures.

Box 69-5

Complications of a Blood Transfusion

- Transfusion reactions
- Circulatory overload
- Septicemia
- Iron overload
- Disease transmission
- Hypocalcemia
- Hyperkalemia
- Citrate toxicity
Box 69-6

Nasogastric Tubes: Intubation Procedures

1. Follow agency procedures.
2. Explain the procedure and its potential discomfort to the client.
3. Position the client in a high-Fowler’s position with pillows behind the shoulders.
4. Determine which nostril is more patent.
5. Measure the length of the tube from the bridge of the nose to the earlobe to the xiphoid process and indicate this length with a piece of tape on the tube (remember the abbreviation NEX, which stands for nose, earlobe, and xiphoid process).
6. If the client is conscious and alert, have him or her swallow or drink water (follow agency procedure).
7. Lubricate the tip of the tube with water-soluble lubricant.
8. Gently insert the tube into the nasopharynx and advance the tube.
9. When the tube nears the back of the throat (first black measurement on the tube), instruct the client to swallow or drink sips of water (unless contraindicated). If resistance is met, slowly rotate and aim the tube downward and toward the closer ear; in the intubated or semiconscious client, flex the head toward the chest while passing the tube.
10. Immediately withdraw the tube if any change is noted in the client’s respiratory status.
11. Following insertion, obtain an abdominal x-ray study to confirm placement of the tube.
12. Connect the tube to suction, to either the intermittent or the continuous suction setting, as prescribed if the purpose of the tube is for decompression.
13. Secure the tube to the client’s nose with adhesive tape and to the client’s gown (follow agency procedure and check for client allergy to tape).
14. Observe the client for nausea, vomiting, abdominal fullness, or distention and monitor gastric output.
15. Check residual volumes every 4 hours, before each feeding, and before giving medications. Aspirate all stomach contents (residual) and measure the amount. Reinstill residual contents to prevent excessive fluid and electrolyte losses, unless the residual contents appear abnormal or the volume is large (greater than 250 mL). Always follow agency procedure. Withhold a feeding if the residual amount is more than 100 mL or according to agency or nutritional consult recommendations.
16. Before the instillation of any substance through the tube (i.e., irrigation solution, feeding, medications), aspirate stomach contents and test the pH (a pH of 3.5 or lower indicates that the tip of the tube is in a gastric location).
17. If irrigation is indicated, use normal saline solution (check agency procedure).
18. Observe the client for fluid and electrolyte balance.
19. Instruct the client about movement to prevent nasal irritation and dislodgment of the tube.
20. On a daily basis, remove the adhesive tape that is securing the tube to the nose and clean and dry the skin, assessing for excoriation; then reapply the tape.

Note: Gastrostomy or jejunostomy tubes are surgically inserted. A dressing is placed at the site of insertion. The dressing needs to be removed, the skin needs to be cleansed (with a solution determined by the health care provider or agency procedure), and a new sterile dressing needs to be applied every 8 hours (or as specified by agency policy). The skin at the insertion site is checked for signs of excoriation, infection, or other abnormalities, such as leakage of the feeding solution.

Adapted from Potter P, Perry A, Stockert P, Hall A: Fundamentals of nursing, ed 8, St. Louis, 2013, Mosby
1. Follow agency procedures.
2. Explain the procedure and its potential discomfort to the client.
3. Place the client in position for catheterization:
   - **Female**: Assist to dorsal recumbent position (supine with knees flexed).
     Support legs with pillows to reduce muscle tension and promote comfort.
   - **Male**: Assist to supine position with thighs slightly abducted.
4. Wearing clean gloves, wash perineal area with soap and water as needed; dry thoroughly. Remove and discard gloves; perform hand hygiene.
5. Open outer wrapping of the catheter kit, remembering that all components of the catheterization tray are sterile (all supplies are arranged in the box in order of sequence of use).
6. Apply waterproof sterile drape (when packed as first item in tray).
7. Urinary catheter procedure with specifics for male and female:
   a. Place a sterile drape with plastic side down under the client’s...
b. Don sterile gloves using sterile technique.
c. Pick up fenestrated drape from tray. Allow it to unfold without touching nonsterile surface. Apply drape over perineum, exposing labia or penis.
d. While maintaining sterility, open packet of lubricant and squeeze out on sterile field. Lubricate catheter tip by dipping it into water-soluble gel, 2.5 to 5 cm (1 to 2 inches) for women and 12.5 to 17.5 cm (5 to 7 inches) for men. Attach prefilled syringe to balloon port. Prepare cotton balls or swab sticks for cleansing perineal area.
e. Remember with a sterile technique, the sterile field and gloved hands must be maintained above the level of the waist, the 1-inch (2.5 cm) border on the field is considered contaminated, and the nurse cannot turn her or his back to the field at any time.
f. Catheter insertion

Female: The female should be positioned in a dorsal recumbent position with the legs open to allow for full visualization and maintenance of the sterile field. With nondominant hand, fully expose urethral meatus by spreading labia, taking care to not allow the labia to close. Using forceps in sterile dominant hand, pick up cotton ball or swab sticks saturated with antiseptic solution, wiping from front to back (from clitoris toward anus). Using a new cotton ball or swab for each area you clean, wipe far labial fold, near labial fold, and directly over center of urethral meatus. Pick up and hold catheter 7.5 to 10 cm (3 to 4 inches) from catheter tip. Advance catheter a total of 7.5 cm (3 inches) in adult or until urine flows out of catheter end. When urine appears, advance catheter another 2.5 to 5 cm (1 to 2 inches). Do not use force to insert catheter.

Male: Use of square sterile drape is optional; you may apply fenestrated drape with fenestrated slit resting over penis. Grasp penis at shaft just below glans. (If client is not circumcised, retract foreskin with nondominant hand.) With dominant hand, pick up antiseptic-soaked cotton ball with forceps or swab stick and clean penis. Move cotton ball or swab in circular motion from urethral meatus down to base of glans. Repeat cleaning 2 more times, using clean cotton ball/stick each time. Pick up catheter with gloved dominant hand and insert catheter by lifting penis to position perpendicular to client’s body and apply light traction. Advance catheter 17.5 to 22.5 cm (7 to 9 inches) in adult or until urine flows out of catheter end. Advance an additional 2.5 to 5 cm (1 to 2 inches) after urine appears. Lower penis and hold catheter securely in nondominant hand.

8. Inflate balloon fully per manufacturer’s directions and gently pull back on the buttocks.
catheter until resistance is felt.
9. Secure catheter tubing to inner thigh with agency-approved securing device, such as a StatLock.
10. Record type and size of catheter inserted, amount of fluid used to inflate the balloon, characteristics and amount of urine, specimen collection if appropriate, client’s response to procedure, and that teaching was completed.

Removal Procedure

1. Follow agency procedures.
2. Explain the procedure and its potential discomfort to the client.
3. Position the client in the same position as during catheterization.
4. Remove the securing device and place the towel between a female client’s thighs or over a male client’s thighs.
5. Insert a 10-mL syringe into the balloon injection port. Slowly withdraw all of the solution to deflate the balloon totally.
6. After deflation, explain to the client that she or he may feel a burning sensation as the catheter is withdrawn. Pull the catheter out smoothly and slowly.
7. Assess the client’s urinary function by noting the first voiding after catheter removal and documenting the time and amount of voiding for the next 24 hours.

**Box 69-8**

**Some Types of Tracheostomy Tubes**

**Double-Lumen Tube**

The double-lumen tube has the following parts:

*Outer cannula*—fits into the stoma and keeps the airway open. The face plate indicates the size and type of tube and has small holes on both sides for securing the tube with tracheostomy ties or another device.

*Inner cannula*—fits snugly into the outer cannula and locks into place. It provides the universal adaptor for use with the ventilator and other respiratory therapy equipment. Some may be removed, cleaned, and reused; others are disposable.

*Obturator*—a stylet with a smooth end used to facilitate the direction of the tube when inserting or changing a tracheostomy tube. The obturator is removed immediately after tube placement; an obturator is always kept with the client and at the bedside in case of accidental decannulation.

*Cuff*—when inflated, seals the airway. The cuffed tube is used for mechanical ventilation, preventing aspiration of oral or gastric secretions, or for the client receiving a tube feeding to prevent aspiration. A pilot balloon attached to the outside of the tube indicates the presence or absence of air in the cuff.
**Single-Lumen Tube**
The single-lumen tube is similar to the double-lumen tube except that there is no inner cannula. More intensive nursing care is required with this tube because there is no inner cannula to ensure a patent lumen.

**Fenestrated Tube**
The fenestrated tube has a precut opening (fenestration) in the upper posterior wall of the outer cannula. The tube is used to wean the client from a tracheostomy by ensuring that the client can tolerate breathing through her or his natural airway before the entire tube is removed. This tube allows the client to speak.

**Cuffed Fenestrated Tube**
The cuffed fenestrated tube facilitates mechanical ventilation and speech and often is used for clients with spinal cord paralysis or neuromuscular disease who do not require ventilation at all times. When not on the ventilator, the client can have the cuff deflated and the tube capped (see Fig. 69-11 for cuffed fenestrated tube with red cap) for speech. A cuffed fenestrated tube is never used in weaning from a tracheostomy, because the cuff, even fully deflated, may partially obstruct the airway.

**Table 69-5**
**Complications of a Tracheostomy**
<table>
<thead>
<tr>
<th>Complication and Description</th>
<th>Manifestations</th>
<th>Management</th>
<th>Prevention</th>
</tr>
</thead>
</table>
| Tracheomalacia: Constant pressure exerted by the cuff causes tracheal dilation and erosion of cartilage. | ▪ An increased amount of air is required in the cuff to maintain the seal.  
▪ A larger tracheostomy tube is required to prevent an air leak at the stoma.  
▪ Food particles are seen in tracheal secretions.  
▪ The client does not receive the set tidal volume on the ventilator. | ▪ Monitor client; no special management is needed unless bleeding or airway problems occur | ▪ Monitor cuff pressure and air volume closely to detect changes.  
▪ Use an uncuffed tube as soon as possible. |
| Tracheal stenosis: Narrowed tracheal lumen is the result of scar formation from irritation of tracheal mucosa by the cuff. | ▪ Stenosis is usually seen after the cuff is deflated or the tracheostomy tube is removed.  
▪ The client has increased coughing, inability to expectorate secretions, or difficulty breathing and talking. | ▪ Tracheal dilation or surgical intervention is used. | ▪ Prevent pulling of and traction on the tracheostomy tube.  
▪ Properly secure the tube in the midline position.  
▪ Maintain cuff pressure.  
▪ Minimize oronasal intubation time. |
| Tracheoesophageal fistula (TEF): Excessive cuff pressure causes erosion of the posterior wall of the trachea. A hole is created between the trachea and the anterior esophagus. The client at highest risk also has a nasogastric tube present. | Similar to tracheomalacia:  
▪ Food particles are seen in tracheal secretions.  
▪ Increased air in cuff is needed to achieve a seal.  
▪ The client has increased coughing and choking while eating.  
▪ The client does not receive the set tidal volume on the ventilator. | ▪ Suction; manually administer oxygen by mask to prevent hypoxemia.  
▪ Use a small soft feeding tube instead of a nasogastric tube for tube feedings.  
▪ A gastrostomy or jejunostomy may be performed.  
▪ Monitor the client with a nasogastric tube closely; assess for TEF and aspiration. | ▪ Maintain cuff pressure.  
▪ Monitor the amount of air needed for inflation to detect changes.  
▪ Progress to a deflated or cuffless tube as soon as possible. |
<table>
<thead>
<tr>
<th>Complication and Description</th>
<th>Manifestations</th>
<th>Management</th>
<th>Prevention</th>
</tr>
</thead>
</table>
| Trachea–innominate artery fistula: A malpositioned tube causes its distal tip to push against the lateral wall of the trachea. Continued pressure causes necrosis and erosion of the innominate artery. This is a medical emergency. | - The tracheostomy tube pulsates in synchrony with the heartbeat.  
- There is heavy bleeding from the stoma.  
- This is a life-threatening complication. | - Apply direct pressure to the innominate artery at the stoma site.  
- The tracheostomy tube will be removed immediately.  
- Prepare the client for immediate repair surgery. | - Use the correct tube size and length, and maintain the tube in midline position.  
- Prevent pulling or tugging of the tracheostomy tube.  
- Immediately notify the primary health care provider (PHCP) of a pulsating tube. |
| Tube obstruction | - Difficulty breathing  
- Noisy respirations  
- Difficulty inserting the suction catheter  
- Thick, dry secretions  
- Unexplained peak pressures if client is on a mechanical ventilator | - The PHCP repositions or replaces the tube if obstruction occurs as a result of cuff prolapse over the end of the tube. | - Assist the client to cough and deep-breathe.  
- Provide humidification and suctioning.  
- Clean the inner cannula regularly. |
| Tube dislodgment | - Difficulty breathing  
- Noisy respirations  
- Restlessness  
- Excessive coughing  
- Audible wheeze or stridor | - Be familiar with institutional policy regarding replacement of a tracheostomy tube as a nursing procedure.  
- During the first 72 hours following surgical placement of the tracheostomy, the nurse manually ventilates the client by using a manual resuscitation (Ambu) bag while another nurse calls the Rapid Response Team for help.  
- 72 hours following surgical placement of the tracheostomy:  
- Extend the client's neck and open the tissues of the stoma to secure the airway.  
- Grasp the retention sutures (if they are present) to spread the opening.  
- Use a tracheal dilator (curved clamp) to hold the stoma open.  
- Prepare to insert a tracheostomy tube; place the obturator into the tracheostomy tube, insert the tube, and remove the obturator.  
- Maintain ventilation by resuscitation (Ambu) bag.  
- Assess airflow and bilateral breath sounds.  
- If unable to secure an airway, call the Rapid Response Team and the anesthesiologist. | - Secure the tube in place.  
- Minimize manipulation of and traction on the tube.  
- Ensure that the client does not pull on the tube.  
- Ensure that a tracheostomy tube of the same type and size is at the client's bedside. |

Box 69-10

Wound Coverings

Biological

Amniotic Membranes

- Amniotic membrane from human placenta is used; it adheres to the wound.
• Effective as a dressing until epithelial cell regrowth occurs
• Requires frequent changes/application because it does not develop a blood supply and disintegrates in about 48 hours

Allograft or Homograft (Human Tissue)

• Donated human cadaver skin provided through a skin bank
• Monitor for wound exudate and signs of infection.
• Rejection can occur within 24 hours
• Risk of transmitting bloodborne infection exists when used.

Xenograft or Heterograft (Animal Tissue)

• Pigskin harvested after slaughter is preserved for storage and use.
• Monitor for infection and wound adherence.
• Placed over granulation tissue; replaced every 2 to 5 days until wound heals naturally or until closure with autograft is complete

Cultured Skin

• Grown in laboratory from a small specimen of epidermal cells from an unburned portion of the client’s body
• Cell sheets are grafted on the client to generate permanent skin surface.
• Cell sheets are not durable; care must be taken when applying to ensure adherence and prevent sloughing.

Artificial Skin

• Consists of 2 layers—silastic epidermis and porous dermis made from bovine hide collagen and shark cartilage
• After application, fibroblasts move into the collagen part of the artificial skin and create a structure similar to normal dermis.
• Artificial dermis then dissolves; it is then replaced with normal blood vessels and connective tissue called neodermis.
• Neodermis supports the standard autograft placed over it when the Silastic layer is removed.

Biosynthetic

• Combination of biosynthetic and synthetic materials
• Placed in contact with the wound surface; forms an adherent bond until epithelialization occurs
• Porous substance allows exudate to pass through.
• Monitor for wound exudate and signs of infection.
**Synthetic**

- Applied directly to the surface of a clean or surgically prepared wound; remains in place until it falls off or is removed
- Covering is transparent or translucent; therefore, wound can be inspected without removing dressing.
- Pain at the wound site is reduced because covering prevents contact of the wound with air.

**Autograft**

- Skin taken from a remote unburned area of the client’s own body; transplanted to cover burn wound
- Graft placed on a clean granulated bed or over surgically excised area of the burn
- Provides for permanent skin coverage

**Box 69-11**

**Diabetes and Client Education: Guidelines During Illness**

- Take insulin or oral antidiabetic medications as prescribed.
- Determine the blood glucose level and test the urine for ketones every 3 to 4 hours.
- If the usual meal plan cannot be followed, substitute soft foods 6 to 8 times a day.
- If vomiting, diarrhea, or fever occurs, consume liquids every 30 to 60 minutes to prevent dehydration and to provide calories.
- Notify the primary health care provider (PHCP) if vomiting, diarrhea, or fever persists; if blood glucose levels are higher than 250 to 300 mg/dL (14 to 17 mmol/L); when ketonuria is present for more than 24 hours; when unable to take food or fluids for a period of 4 hours; or when illness persists for more than 2 days.
FIG. 69-20 Surgical shunting diverts portal venous blood flow from the liver to decrease portal and esophageal pressure.

Box 69-12
Chest Physiotherapy: Contraindications and Interventions

Contraindications

- Unstable vital signs
- Increased intracranial pressure
- Bronchospasm
- History of pathological fractures
- Rib fractures
- Chest incisions

Interventions

- Assess for contraindications for performing chest physiotherapy (CPT)
- Perform CPT in the morning on arising, 1 hour before meals, or 2 to 3 hours after meals.
- Stop CPT if pain occurs.
- If the client is receiving a tube feeding, stop the feeding and aspirate for residual before beginning CPT.
- Administer the bronchodilator (if prescribed) 15 minutes before the procedure.
- Place a layer of material (gown or pajamas) between the hands or percussion device and the client’s skin.
- Position the client for postural drainage based on assessment.
- Percuss the area for 1 to 2 minutes.
- Vibrate the same area while the client exhales 4 or 5 deep breaths.
• Monitor for respiratory tolerance to the procedure.
• Stop the procedure if cyanosis or exhaustion occurs.
• Maintain the position for 5 to 20 minutes after the procedure.
• Repeat in all necessary positions until the client no longer expectorates mucus.
• Dispose of sputum properly.
• Provide mouth care after the procedure.

Table 69-10

Supplemental Oxygen Delivery Systems
<table>
<thead>
<tr>
<th>Device</th>
<th>Oxygen Delivered</th>
<th>Nursing Considerations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nasal cannula (nasal prongs) (see Fig. 69-24)</td>
<td>- 4-6 L/min for oxygen concentration (FIO₂) of 24% (at 1 L/min) to 44% (at 6 L/min)</td>
<td>- Easily tolerated</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Can dislodge easily. Does not get in the way of eating or talking.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Effective oxygen concentration can be delivered. Allows the client to breathe through the nose or mouth.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Ensure that prongs are in the nares with openings facing the client.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Assess nasal mucosa for irritation from drying effect of higher flow rates.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Assess skin integrity, as tubing can irritate skin.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Add humidification as prescribed and check water levels.</td>
</tr>
<tr>
<td>Simple face mask (see Fig. 69-23)</td>
<td>- 5-8 L/min oxygen flow for FIO₂ of 40%-60%.</td>
<td>- Interferes with eating and talking.</td>
</tr>
<tr>
<td></td>
<td>- Minimum flow of 5 L/min needed to flush CO₂ from mask.</td>
<td>- Can be warm and confining.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Ensure that mask fits securely over nose and mouth.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Remove saliva and mucus from the mask.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Provide skin care to area covered by mask.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Provide emotional support to decrease anxiety in the client who feels claustrophobic.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Monitor for risk of aspiration from inability of client to clear mouth (i.e., if vomiting occurs).</td>
</tr>
<tr>
<td>Venturi mask (Ventimask) (see Fig. 69-26)</td>
<td>- 4-10 L/min oxygen flow for FIO₂ of 24%-55%.</td>
<td>- Keep the air entrainment port for the adapter open and uncovered to ensure adequate oxygen delivery.</td>
</tr>
<tr>
<td></td>
<td>- Delivers exact desired selected concentrations of O₂</td>
<td>- Keep mask snug on the face and ensure tubing is free of kinks, because the FIO₂ is altered if kinking occurs or if the mask fits poorly.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Assess nasal mucosa for irritation; humidity or aerosol can be added to the system as needed.</td>
</tr>
<tr>
<td>Partial rebreather mask (mask with reservoir bag)</td>
<td>- 6-15 L/min oxygen flow for FIO₂ of 70%-90%</td>
<td>- The client rebreathes one-third of the exhaled tidal volume, which is high in oxygen, thus providing a high FIO₂.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Adjust flow rate to keep the reservoir bag two-thirds full during inspiration.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Keep mask snug on face.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Make sure the reservoir bag does not twist or kink.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Deflation of the bag results in decreased oxygen delivered and rebreathing of exhaled air.</td>
</tr>
<tr>
<td>Nonrebreather mask (see Fig. 69-27)</td>
<td>FIO₂ of 60%-100% at a rate of flow that maintains the bag two-thirds full</td>
<td>- Adjust flow rate to keep the reservoir bag inflated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Remove mucus and saliva from the mask.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Provide emotional support to decrease anxiety in the client who feels claustrophobic.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Ensure that the valves and flaps are intact and functional during each breath (valves should open during expiration and close during inspiration).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Make sure the reservoir bag does not twist or kink or that the oxygen source does not disconnect; otherwise, the client will suffocate.</td>
</tr>
<tr>
<td>Tracheostomy collar and T-bar or T-piece, endotracheal tube (face tent; face shield) (see Fig. 69-26)</td>
<td>- The tracheostomy collar can be used to deliver the desired amount of oxygen to a client with a tracheostomy.-</td>
<td>- Ensure that aerosol mist escapes from the vents of the delivery system during inspiration and expiration.</td>
</tr>
<tr>
<td></td>
<td>- A special adaptor (T-bar or T-piece) can be used to deliver any desired FIO₂ to client with tracheostomy, laryngectomy, or endotracheal tube.</td>
<td>- Empty condensation from the tubing to prevent the client from being lavaged with water and to promote an adequate oxygen flow rate (remove and clean the tubing at least every 4 hr).</td>
</tr>
<tr>
<td></td>
<td>- The face tent provides 8-12 L/min and the FIO₂ varies due to environmental loss.</td>
<td>- Keep the exhalation port in the T-piece open and uncovered (if the port is occluded, the client can suffocate).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Position the T-piece so that it does not pull on the tracheostomy or endotracheal tube and cause erosion of the skin at the tracheostomy insertion site.</td>
</tr>
</tbody>
</table>
A nasal cannula (prongs).

**Box 69-13**

**Nasal High-Flow (NHF) Respiratory Therapy**

- Comfortably delivers high flows of heated and humidified oxygen through a wide-bore nasal cannula and humidification system
- Can deliver nasal flow rates up to 50 to 60 L/minute to deliver humidified high-flow oxygen therapy
FIG. 69-22 A simple face mask used to deliver oxygen.

</thead>
<tbody>
<tr>
<td>Tidal volume</td>
<td>The volume of air that the client receives with each breath</td>
</tr>
<tr>
<td>Rate</td>
<td>The number of ventilator breaths delivered per minute</td>
</tr>
<tr>
<td>Sighs</td>
<td>The volumes of air that are 1.5-2 times the set tidal volume, delivered 6-10 times per hour; may be used to prevent atelectasis</td>
</tr>
<tr>
<td>Fraction of inspired oxygen (FiO₂)</td>
<td>The oxygen concentration delivered to the client; determined by the client’s condition and ABG levels</td>
</tr>
<tr>
<td>Peak airway inspiratory pressure</td>
<td>The pressure needed by the ventilator to deliver a set tidal volume at a given compliance. Monitoring peak airway inspiratory pressure reflects changes in compliance of the lungs and resistance in the ventilator or client.</td>
</tr>
<tr>
<td>Continuous positive</td>
<td>The application of positive airway pressure throughout the entire respiratory cycle for</td>
</tr>
</tbody>
</table>

Airway Pressure

Spontaneously breathing clients
Keeps the alveoli open during inspiration and prevents alveolar collapse; used primarily as a weaning modality
No ventilator breaths are delivered, but the ventilator delivers oxygen and provides monitoring and an alarm system; the respiratory pattern is determined by the client’s efforts.

Positive end-expiratory pressure (PEEP)
Positive pressure is exerted during the expiratory phase of ventilation, which improves oxygenation by enhancing gas exchange and preventing atelectasis.
The need for PEEP indicates a severe gas exchange disturbance.
Higher levels of PEEP (more than 15 cm H₂O) increase the chance of complications, such as barotrauma tension pneumothorax.

Pressure support
The application of positive pressure on inspiration that eases the workload of breathing.
May be used in combination with PEEP as a weaning method.
As the weaning process continues, the amount of pressure applied to inspiration is gradually decreased.

ABG, Arterial blood gas.

**Box 69-14**

**Causes of Ventilator Alarms**
Collaborate with respiratory therapy in troubleshooting and addressing ventilator alarms.

**High-Pressure Alarm**

- Increased secretions are in the artificial airway or the client’s own airway.
- Wheezing or bronchospasm is causing decreased airway size.
- The endotracheal tube is displaced.
- The ventilator tube is obstructed because of water or a kink in the tubing.
- Client coughs, gags, or bites on the oral endotracheal tube.
- Client is anxious or fights the ventilator.

**Low-Pressure Alarm**

- Disconnection or leak in the ventilator or in the client’s airway cuff occurs.
- The client stops spontaneous breathing.
FIG. 69-27  Pneumothorax. Air in the pleural space causes the lungs to collapse around the hilus and may push the mediastinal contents (heart and great vessels) toward the other lung.

Box 69-15  
Assessment Findings: Pneumothorax

- Absent or markedly decreased breath sounds on affected side
- Cyanosis
- Decreased chest expansion unilaterally
- Dyspnea
- Hypotension
- Sharp chest pain
- Subcutaneous emphysema as evidenced by crepitus on palpation
- Sucking sound with open chest wound
- Tachycardia
- Tachypnea
- Tracheal deviation to the unaffected side with tension pneumothorax
Cardiac pressure waveforms can be visualized on the monitor.

**Box 69-16**

**Home Care Instructions for the Client Who Has Had Cardiac Surgery**

- Progressive return to activities at home
- Limiting of pushing or pulling activities for 6 weeks following discharge
- Maintenance of incisional care and reporting signs of redness, swelling, or drainage
- Sternotomy incision heals in about 6 to 8 weeks
- Avoidance of crossing legs; wearing elastic hose as prescribed until edema subsides, and elevating the surgical limb (if used to obtain the graft) when sitting in a chair
- Use of prescribed medications
- Dietary measures, including the avoidance of saturated fats and cholesterol and the use of salt
- Resumption of sexual intercourse on the advice of the health care provider after exercise tolerance is assessed (usually, if the client can walk 1 block or climb 2 flights of stairs without symptoms, she or he can resume sexual activity safely)
Box 69-17
Types of Continuous Renal Replacement Therapy

- Continuous venovenous hemofiltration (CVVH)
- Continuous arteriovenous hemofiltration (CAVH)
- Continuous venovenous hemodialysis (CVVHD)
- Continuous arteriovenous hemodialysis (CAVHD)
- Slow continuous ultrafiltration (SCUF)

Box 69-18
Types of Head Injuries

Concussion

- Concussion is a jarring of the brain within the skull; there may or may not be a loss of consciousness.

Contusion

- Contusion is a bruising type of injury to the brain tissue.
- Contusion may occur along with other neurological injuries, such as subdural or extradural collections of blood.

Skull Fractures

- Linear
- Depressed
- Compound
- Comminuted

Epidural Hematoma

- The most serious type of hematoma, epidural hematoma forms rapidly and results from arterial bleeding.
- The hematoma forms between the dura and the skull from a tear in the meningeal artery.
- It is often associated with temporary loss of consciousness, followed by a lucid period that then rapidly progresses to a coma.
- Epidural hematoma is a surgical emergency.

Subdural Hematoma
Subdural hematoma forms slowly and results from a venous bleed. It occurs under the dura as a result of tears in the veins crossing the subdural space.

**Intracerebral Hemorrhage**

- Intracerebral hemorrhage occurs when a blood vessel within the brain ruptures, allowing blood to leak inside the brain.

**Subarachnoid Hemorrhage**

- A subarachnoid hemorrhage is bleeding into the subarachnoid space. It may occur as a result of head trauma or spontaneously, such as from a ruptured cerebral aneurysm.

**Box 69-19**

**Nursing Care Following Craniotomy**

- Monitor vital signs and neurological status every 30 to 60 minutes.
- Monitor for increased intracranial pressure (ICP).
- Monitor for decreased level of consciousness, motor weakness or paralysis, aphasia, visual changes, and personality changes.
- Maintain mechanical ventilation and slight hyperventilation for the first 24 to 48 hours as prescribed to prevent increased ICP.
- Assess the primary health care provider’s (PHCP’s) prescription regarding client positioning.
- Avoid extreme hip or neck flexion, and maintain the head in a midline neutral position.
- Provide a quiet environment.
- Monitor the head dressing frequently for signs of drainage.
- Mark any area of drainage at least once each nursing shift for baseline comparison.
- Monitor the drain, which may be in place for 24 hours; maintain suction on the drain as prescribed.
- Measure drainage from the drain every 8 hours, and record the amount and color.
- Notify the PHCP if drainage is more than the normal amount of 30 to 50 mL per shift.
- Notify the PHCP immediately of excessive amounts of drainage or a saturated head dressing.
- Record strict measurement of hourly intake and output.
- Maintain fluid restriction at 1500 mL/day as prescribed.
• Monitor electrolyte levels.
• Monitor for dysrhythmias, which may occur as a result of fluid or electrolyte imbalance.
• Apply ice packs or cool compresses as prescribed; expect periorbital edema and ecchymosis of 1 or both eyes.
• Provide range-of-motion exercises every 8 hours.
• Place antiembolism stockings on the client as prescribed.
• Administer antiseizure medications, antacids, corticosteroids, and antibiotics as prescribed.
• Administer analgesics such as codeine sulfate or acetaminophen as prescribed for pain.

Box 69-20
Client Positioning Following Craniotomy

• Positions prescribed following a craniotomy vary with the type of surgery and the specific postoperative surgeon’s prescription.
• Always check the surgeon’s prescription regarding client positioning.
• Incorrect positioning may cause serious and possibly fatal complications.

Removal of a Bone Flap for Decompression

• To facilitate brain expansion, the client should be turned from the back to the nonoperative side, but not to the side on which the operation was performed.

Posterior Fossa Surgery

• To protect the operative site from pressure and minimize tension on the suture line, position the client on the side, with a pillow under the head for support, and not on the back.

Infratentorial Surgery

• Infratentorial surgery involves surgery below the tentorium of the brain.
• The surgeon may prescribe a flat position without head elevation or may prescribe that the head of the bed be elevated at 30 to 45 degrees.
• Do not elevate the head of the bed in the acute phase of care following surgery without a surgeon’s prescription.

Supratentorial Surgery

• Supratentorial surgery involves surgery above the tentorium of the brain.
• The surgeon may prescribe that the head of the bed be elevated at 30 degrees to promote venous outflow through the jugular veins.
• Do not lower the head of the bed in the acute phase of care following surgery without a surgeon’s prescription.

Box 69-21
Medications for Increased Intracranial Pressure

Antiseizure

• Seizures increase metabolic requirements and cerebral blood flow and volume, thus increasing intracranial pressure (ICP).
• Medications may be given prophylactically to prevent seizures.

Antipyretics and Muscle Relaxants

• Temperature reduction decreases metabolism, cerebral blood flow, and thus ICP.
• Antipyretics prevent temperature elevations.
• Muscle relaxants prevent shivering.

Blood Pressure Medication

• Blood pressure medication may be required to maintain cerebral perfusion at a normal level.
• Notify the primary health care provider if the blood pressure range is lower than 100 or higher than 150 mm Hg systolic.

Corticosteroids

• Corticosteroids stabilize the cell membrane and reduce leakiness of the blood–brain barrier.
• Corticosteroids decrease cerebral edema.
• A histamine blocker may be administered to counteract the excess gastric secretion that occurs with the corticosteroid.
• Clients must be withdrawn slowly from corticosteroid therapy to reduce the risk of adrenal crisis.

Intravenous Fluids

• Fluids are administered intravenously; an infusion pump is always used to control the amount administered.
• Infusions are monitored closely because of the risk of promoting additional
cerebral edema and fluid overload.

**Hyperosmotic Agent**

- A hyperosmotic agent increases intravascular pressure by drawing fluid from the interstitial spaces and from the brain cells.
- Monitor renal function.
- Diuresis is expected.

---

**Box 69-22**

**Surgical Intervention for Chronic Increased Intracranial Pressure: Ventriculoperitoneal Shunt**

**Description**

- A ventriculoperitoneal shunt diverts cerebrospinal fluid from the ventricles into the peritoneum.

**Postprocedure Interventions**

- Position the client supine and turn from the back to the nonoperative side.
- Monitor for signs of increasing intracranial pressure resulting from shunt failure.
- Monitor for signs of infection.
Box 69-23

Manifestations: Neurogenic Shock, Spinal Shock, and Autonomic Dysreflexia

**Neurogenic Shock**
- Hypotension
- Bradycardia

**Spinal Shock**
- Flaccid paralysis
- Loss of reflex activity below the level of the injury
- Bradycardia
- Hypotension
- Paralytic ileus

**Autonomic Dysreflexia**
• Sudden onset, severe throbbing headache
• Severe hypertension and bradycardia
• Flushing above the level of the injury
• Pale extremities below the level of the injury
• Nasal stuffiness
• Nausea
• Dilated pupils or blurred vision
• Sweating
• Piloerection (goose bumps)
• Restlessness and a feeling of apprehension

**Box 69-24**

**Client Education for a Halo Fixation Device**

• Notify the primary health care provider (PHCP) if the halo vest (jacket) or ring bolts loosen.
• Use fleece or foam inserts to relieve pressure points.
• Keep the vest lining dry.
• Clean the pin site daily.
• Notify the PHCP if redness, swelling, drainage, open areas, pain, tenderness, or a clicking sound occurs from the pin site.
• A sponge bath or tub bath is allowed; showers are not allowed.
• Assess the skin under the vest daily for breakdown, using a flashlight.
• Do not use any products other than shampoo on the hair.
• When shampooing the hair, cover the vest with plastic.
• When getting out of bed, roll onto the side and push on the mattress with the arms.
• Never use the metal frame for turning or lifting.
• Use a rolled towel or pillowcase between the back of the neck and bed or next to the cheek when lying on the side, and raise the head of the bed to increase sleep comfort.
• Adapt clothing to fit over the halo device.
• Eat foods high in protein and calcium to promote bone healing.
• Have the correct-sized wrench available at all times for an emergency (tape the wrench to the vest).
• If cardiopulmonary resuscitation is required, the anterior portion of the vest will be loosened and the posterior portion will remain in place to provide stability.
Richmond Agitation-Sedation Scale (RASS)

Box 69-26

Levels of Sedation

- Light sedation: Relieving anxiety with pharmacological measures so that the client can still respond to verbal commands (Richmond Agitation-Sedation Scale).
- Moderate sedation: Depression of the client’s consciousness with pharmacological measures; known as procedural sedation.
- Deep sedation: Depression of the client’s consciousness with pharmacological measures to the point that the client cannot maintain a patent airway.
- General anesthesia: Depression of the client’s consciousness using multiple medications administered by an anesthesiologist or nurse anesthetist.

Adapted from Urden, Stacy, & Lough, (2018), p. 137.
FIG. 69-30  Clinical manifestations of a systemic anaphylactic reaction.

**Box 69-27**

**Sepsis Diagnostic Criteria**

**Signs and Symptoms**

- Fever (temperature above 100.9° F [38.3° C]) or hypothermia (core temperature below 97° F [36° C])
• Tachycardia (heart rate above 90 beats per minute)
• Tachypnea (respiratory rate above 22 breaths per minute)
• Systolic blood pressure (SBP) less than or equal to 100 mm Hg or arterial hypotension (SBP below 90 mm Hg), MAP below 70 mm Hg, or a decrease in SBP of more than 40 mm Hg
• Altered mental status
• Edema or positive fluid balance
• Oliguria
• Ileus (absent bowel sounds)
• Decreased capillary refill or mottling of skin

Laboratory Values

• Hyperglycemia (blood glucose greater than 140 mg/dL (8 mmol/L) in client without diabetes)
• Leukocytosis or leukopenia
• Normal white blood cell count with more than 10% immature bands
• Elevated C-reactive protein
• Elevated procalcitonin
• Serum creatinine increase
• Coagulation abnormalities (INR above 1.5 [1.5] or PTT above 60 seconds [for more than 60 seconds])
• Thrombocytopenia (platelets below 100,000/mm³ (100 × 10⁹/L))
• Hyperbilirubinemia (total bilirubin above 4 mg/dL [68 mc mol/L])
• Hyperlactatemia (above 1 mmol/L)

Practice Questions

856. A client had a 1000-mL bag of 5% dextrose in 0.9% sodium chloride hung at
1500. The nurse making rounds at 1545 finds that the client is complaining of a pounding headache and is dyspneic, experiencing chills, and apprehensive, with an increased pulse rate. The intravenous (IV) bag has 400 mL remaining. The nurse should take which action first?
1. Slow the IV infusion.
2. Sit the client up in bed.
3. Remove the IV catheter.
4. Call the primary health care provider (PHCP).

857. Packed red blood cells have been prescribed for a female client with anemia who has a hemoglobin level of 7.6 g/dL (76 mmol/L) and a hematocrit level of 30% (0.30). The nurse takes the client’s temperature before hanging the blood transfusion and records 100.6° F (38.1° C) orally. Which action should the nurse take?
1. Begin the transfusion as prescribed.
2. Administer an antihistamine and begin the transfusion.
3. Administer 2 tablets of acetaminophen and begin the transfusion.
4. Delay hanging the blood and notify the primary health care provider (PHCP).

858. The nurse is caring for a client experiencing acute lower gastrointestinal bleeding. In developing the plan of care, which priority problem should the nurse assign to this client?
1. Deficient fluid volume related to acute blood loss
2. Risk for aspiration related to acute bleeding in the GI tract
3. Risk for infection related to acute disease process and medications
4. Imbalanced nutrition, less than body requirements, related to lack of nutrients and increased metabolism

859. The nurse is assessing the functioning of a chest tube drainage system in a client with a chest injury who has just returned from the recovery room following a thoracotomy with wedge resection. Which are the expected assessment findings? Select all that apply.

- 1. Excessive bubbling in the water seal chamber
- 2. Vigorous bubbling in the suction control chamber
- 3. Drainage system maintained below the client’s chest
- 4. 50 mL of drainage in the drainage collection chamber
- 5. Occlusive dressing in place over the chest tube insertion site
- 6. Fluctuation of water in the tube in the water seal chamber during inhalation and exhalation

860. A client is brought to the emergency department with partial-thickness burns to his face, neck, arms, and chest after trying to put out a car fire. The nurse should implement which nursing actions for this client? Select all that apply.

- 1. Restrict fluids.
- 3. Administer oxygen as prescribed.
4. Place a cooling blanket on the client.
5. Elevate extremities if no fractures are present.
6. Prepare to give oral pain medication as prescribed.

861. A client is admitted to a hospital with a diagnosis of diabetic ketoacidosis (DKA). The initial blood glucose level is 950 mg/dL (52.9 mmol/L). A continuous intravenous (IV) infusion of short-acting insulin is initiated, along with IV rehydration with normal saline. The serum glucose level is now decreased to 240 mg/dL (13.37 mmol/L). The nurse would next prepare to administer which medication?
   1. An ampule of 50% dextrose
   2. NPH insulin subcutaneously
   3. IV fluids containing dextrose
   4. Phenytoin for the prevention of seizures

862. The nurse is assessing a client with multiple trauma who is at risk for developing acute respiratory distress syndrome. The nurse should assess for which earliest sign of acute respiratory distress syndrome?
   1. Bilateral wheezing
   2. Inspiratory crackles
   3. Intercostal retractions
   4. Increased respiratory rate

863. A client is admitted to the emergency department with chest pain that is consistent with myocardial infarction based on elevated troponin levels. Heart sounds are normal. The nurse should alert the primary health care provider because the vital sign changes and client assessment are most consistent with which complication? Refer to chart.

   Refer to chart.

   1. Cardiogenic shock
   2. Cardiac tamponade
   3. Pulmonary embolism
   4. Dissecting thoracic aortic aneurysm

864. The nurse is caring for a client with chronic kidney disease on continuous replacement renal therapy (CRRT) without the use of a hemodialysis machine. The nurse determines that which parameter is most important in ensuring success of this treatment?
   1. Mean arterial pressure (MAP)
   2. Systolic blood pressure (SBP)
   3. Diastolic blood pressure (DBP)
   4. Central venous pressure (CVP)

865. The nurse is monitoring a client with a head injury for signs of increased intracranial pressure. The nurse would note which trend in vital signs if the intracranial pressure is rising?
   1. Increasing temperature, increasing pulse, increasing respirations,
decreasing blood pressure
2. Increasing temperature, decreasing pulse, decreasing respirations, increasing blood pressure
3. Decreasing temperature, decreasing pulse, increasing respirations, decreasing blood pressure
4. Decreasing temperature, increasing pulse, decreasing respirations, increasing blood pressure

866. A client develops an anaphylactic reaction after receiving morphine. The nurse should plan to institute which actions? **Select all that apply.**
   1. Administer oxygen.
   2. Quickly assess the client’s respiratory status.
   3. Document the event, interventions, and client’s response.
   4. Keep the client supine regardless of the blood pressure readings.
   5. Leave the client briefly to contact a primary health care provider (PHCP).
   6. Start an intravenous (IV) infusion of D5W and administer a 500-mL bolus.

867. A client in shock develops a central venous pressure (CVP) of 2 mm Hg and mean arterial pressure (MAP) of 60 mm Hg. Which prescribed intervention should the nurse implement **first**?
1. Increase the rate of O₂ flow
2. Obtain arterial blood gas results
3. Insert an indwelling urinary catheter
4. Increase the rate of intravenous (IV) fluids

868. A client at risk for shock secondary to pneumonia develops restlessness and is agitated and confused. Urinary output has decreased and the blood pressure is 92/68 mm Hg. The nurse minimally suspects which stage of shock based on this data?
1. Stage 1
2. Stage 2
3. Stage 3
4. Stage 4

869. The nurse is caring for a client hospitalized for heart failure exacerbation and suspects the client may be entering a state of shock. The nurse knows that which intervention is the **priority** for this client?
1. Administration of digoxin
2. Administration of whole blood
3. Administration of intravenous fluids
4. Administration of packed red blood cells

870. Which clinical findings are consistent with sepsis diagnostic criteria? **Select all that apply.**
   1. Urine output 50 mL/hr
2. Hypoactive bowel sounds
3. Temperature of 102° F (38.9° C)
4. Heart rate of 96 beats per minute
5. Mean arterial pressure 65 mm Hg
6. Systolic blood pressure 110 mm Hg

Answers

856. Answer: 1

Rationale: The client’s symptoms are compatible with circulatory overload. This may be verified by noting that 600 mL has infused in the course of 45 minutes. The first action of the nurse is to slow the infusion. Other actions may follow in rapid sequence. The nurse may elevate the head of the bed to aid the client’s breathing, if necessary. The nurse also notifies the PHCP. The IV catheter is not removed; it may be needed for the administration of medications to resolve the complication.

Test-Taking Strategy: Note the strategic word, first. This tells you that more than 1 or all of the options are likely to be correct actions and that the nurse needs to prioritize them according to a time sequence. You must be able to recognize the signs of circulatory overload. From this point, select the option that provides the intervention specific to circulatory overload.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Complex Care: Intravenous Therapy
Health Problem: N/A
Priority Concepts: Fluid and Electrolytes; Perfusion

857. Answer: 4

Rationale: If the client has a temperature higher than 100° F (37.8° C), the unit of blood should not be hung until the primary PHCP is notified and has the opportunity to give further prescriptions. The PHCP likely will prescribe that the blood be administered regardless of the temperature, or may instruct the nurse to administer prescribed acetaminophen and wait until the temperature has decreased before administration, but the decision is not within the nurse’s scope of practice to make. The nurse needs a PHCP’s prescription to administer medications to the client.

Test-Taking Strategy: Eliminate all options that indicate to begin the transfusion, noting that they are comparable or alike. In addition, the options including antihistamine and acetaminophen indicate administering medication to the client, which is not done without a PHCP’s prescription.
**Level of Cognitive Ability:** Synthesizing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Complex Care: Blood Administration  
**Health Problem:** Adult Health: Hematological: Anemias  
**Priority Concepts:** Clinical Judgment; Safety  
**Reference:** Lewis et al. (2017), p. 649.

858. **Answer:** 1

**Rationale:** The priority problem for the client with acute gastrointestinal bleeding among these options is deficient fluid volume related to acute blood loss. This state can result in decreased cardiac output and hypovolemic shock. Although nutrition is a problem, fluid volume deficit is more of a priority. The client is at risk for aspiration and infection, but these are not actual problems at this point in time.

**Test-Taking Strategy:** Note the strategic word *priority*. Recalling that maintaining fluid balance is important for vital bodily functions will assist in directing you to this option. Additionally, note the word *risk* in options 2 and 3.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Analysis  
**Content Area:** Complex Care: Emergency Situations/Management  
**Health Problem:** Adult Health: Gastrointestinal: Lower GI Disorders  

859. **Answer:** 3, 4, 5, 6

**Rationale:** The bubbling of water in the water seal chamber indicates air drainage from the client and usually is seen when intrathoracic pressure is higher than atmospheric pressure; it may occur during exhalation, coughing, or sneezing. Excessive bubbling in the water seal chamber may indicate an air leak, an unexpected finding. Fluctuation of water in the tube in the water seal chamber during inhalation and exhalation is expected. An absence of fluctuation may indicate that the chest tube is obstructed or that the lung has re-expanded and that no more air is leaking into the pleural space. Gentle (not vigorous) bubbling should be noted in the suction control chamber. A total of 50 mL of drainage is not excessive in a client returning to the nursing unit from the recovery room. Drainage that is more than 70 to 100 mL/hr is considered excessive and requires notification of the surgeon. The chest tube insertion site is covered with an occlusive (airtight) dressing to prevent air from entering the pleural space. Positioning the drainage system below the client’s chest allows gravity to drain the pleural space.

**Test-Taking Strategy:** Focus on the subject, expected findings associated with chest tube drainage systems. Thinking about the physiology associated with the functioning of a chest tube drainage system will assist in answering this question. The words *excessive bubbling* and *vigorous bubbling* will assist in eliminating these options.

**Level of Cognitive Ability:** Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Complex Care: Invasive Devices
Health Problem: Adult Health: Respiratory: Chest Injuries
Priority Concepts: Clinical Judgment; Gas Exchange

860. Answer: 2, 3, 5

Rationale: The primary goal for a burn injury is to maintain a patent airway, administer intravenous (IV) fluids to prevent hypovolemic shock, and preserve vital organ functioning. Therefore, the priority actions are to assess for airway patency and maintain a patent airway. The nurse then prepares to administer oxygen. Oxygen is necessary to perfuse vital tissues and organs. An IV line should be obtained and fluid resuscitation started. The extremities are elevated to assist in preventing shock and decrease fluid moving to the extremities, especially in the burn-injured upper extremities. The client is kept warm, because the loss of skin integrity causes heat loss. The client is placed on NPO (nothing by mouth) status because of the altered gastrointestinal function that occurs as a result of a burn injury.

Test-Taking Strategy: Focus on the subject, actions in a burn injury. Think about the pathophysiology that occurs and how the body reacts to a major burn injury. This assists in eliminating options 1, 4, and 6.

Level of Cognitive Ability: Synthesizing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Analysis
Content Area: Complex Care: Emergency Situations/Management
Health Problem: Adult Health: Integumentary: Burns
Priority Concepts: Clinical Judgment; Tissue Integrity

861. Answer: 3

Rationale: Emergency management of DKA focuses on correcting fluid and electrolyte imbalances and normalizing the serum glucose level. If the corrections occur too quickly, serious consequences, including hypoglycemia and cerebral edema, can occur. During management of DKA, when the blood glucose level falls to 250 to 300 mg/dL (13.9 to 16.7 mmol/L), the IV infusion rate is reduced and a dextrose solution is added to maintain a blood glucose level of about 250 mg/dL (13.9 mmol/L), or until the client recovers from ketosis. Fifty percent dextrose is used to treat hypoglycemia. NPH insulin is not used to treat DKA. Phenytoin is not a usual treatment measure for DKA.

Test-Taking Strategy: Note the strategic word, next. Focus on the subject, management of DKA. Eliminate option 2 first, knowing that short-duration (rapid-acting) insulin is used in the management of DKA. Eliminate option 1 next, knowing that this is the treatment for hypoglycemia. Note the words the serum glucose level is now decreased to 240 mg/dL (13.7 mmol/L). This should indicate that the IV solution...
containing dextrose is the next step in the management of care.

**Level of Cognitive Ability:** Synthesizing

**Priority Concepts:** Clinical Judgment; Glucose Regulation  

862. **Answer:** 4

**Rationale:** The earliest detectable sign of acute respiratory distress syndrome is an increased respiratory rate, which can begin from 1 to 96 hours after the initial insult to the body. This is followed by increasing dyspnea, air hunger, retraction of accessory muscles, and cyanosis. Breath sounds may be clear or consist of fine inspiratory crackles or diffuse coarse crackles.

**Test-Taking Strategy:** Note the **strategic word**, *earliest*. Eliminate option 3 first because intercostal retraction is a later sign of respiratory distress. Of the remaining options, recall that adventitious breath sounds (options 1 and 2) would occur later than an increased respiratory rate.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Complex Care: Acute Respiratory Failure  
**Health Problem:** Adult Health: Respiratory: Acute Respiratory Distress Syndrome/Failure  
**Priority Concepts:** Gas Exchange; Perfusion  
**Reference:** Lewis et al. (2017), pp. 1622-1623.

863. **Answer:** 1

**Rationale:** Cardiogenic shock occurs with severe damage (more than 40%) to the left ventricle. Classic signs include hypotension; a rapid pulse that becomes weaker; decreased urine output; and cool, clammy skin. Respiratory rate increases as the body develops metabolic acidosis from shock. Cardiac tamponade is accompanied by distant, muffled heart sounds and prominent neck vessels. Pulmonary embolism presents suddenly with severe dyspnea accompanying the chest pain. Dissecting aortic aneurysms usually are accompanied by back pain.

**Test-Taking Strategy:** Note the **strategic word**, *most*. Recalling that the early serious complications of myocardial infarction include dysrhythmias, cardiogenic shock, and sudden death will direct you to the correct option. No information in the question is associated with the remaining options.

**Level of Cognitive Ability:** Synthesizing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Analysis  
**Content Area:** Complex Care: Shock  
**Health Problem:** Adult Health: Cardiovascular: Shock
**Priority Concepts:** Clinical Judgment; Perfusion  

864. **Answer:** 1

**Rationale:** Continuous renal replacement therapy (CRRT) provides continuous ultrafiltration of extracellular fluid and clearance of urinary toxins over a period of 8 to 24 hours; it is used primarily for clients with acute kidney injury (AKI) or critically ill clients with chronic kidney disease (CKD) who cannot tolerate hemodialysis. Water, electrolytes, and other solutes are removed as the client’s blood passes through a hemofilter. If CRRT does not require a hemodialysis machine, the client’s MAP needs to be maintained above 60 mm Hg, and arterial and venous access sites are necessary. The SBP, DBP, and CVP may be monitored but each of these measures a component of the cardiovascular status rather than the complete cardiac cycle.  
**Test-Taking Strategy:** Note the strategic words, most important. Recall that the mean arterial pressure is a measure that takes into account the complete cardiac cycle and is therefore the umbrella option that encompasses all other options.  
**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity

**Reference:** Lewis et al. (2017), pp. 1091-1092.

865. **Answer:** 2

**Rationale:** A change in vital signs may be a late sign of increased intracranial pressure. Trends include increasing temperature and blood pressure and decreasing pulse and respirations. Respiratory irregularities also may occur.  
**Test-Taking Strategy:** Focus on the subject, signs of increased intracranial pressure. If you remember that the temperature rises, you are able to eliminate options 3 and 4. If you know that the client becomes bradycardic, or know that the blood pressure rises, you are able to select the correct option.  
**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Complex Care: Emergency Situations/Management  
**Health Problem:** Adult Health: Neurological: Head Injury/Trauma  
**Priority Concepts:** Clinical Judgment; Intracranial Regulation  
**Reference:** Lewis et al. (2017), pp. 1318-1319.

866. **Answer:** 1, 2, 3

**Rationale:** An anaphylactic reaction requires immediate action, starting with quickly assessing the client’s respiratory status. Although the PHCP and the Rapid Response Team must be notified immediately, the nurse must stay with the client. Oxygen is administered and an IV of normal saline is started and infused per PHCP...
prescription. Documentation of the event, actions taken, and client outcomes needs to be done. The head of the bed should be elevated if the client’s blood pressure is normal.

**Test-Taking Strategy:** Focus on the **subject**, interventions the nurse takes for an anaphylactic reaction. Read each option carefully and remember that this is an emergency. Think about the pathophysiology that occurs in this reaction to answer correctly.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Complex Care: Emergency Situations/Management  
**Health Problem:** Adult Health: Immune: Hypersensitivity Reactions and Allergy  
**Priority Concepts:** Clinical Judgment; Immunity  

867. **Answer:** 4  

**Rationale:** The MAP and CVP are both low for this client, indicating a shock state. Shock is the result of inadequate tissue perfusion. Fluid volume should be immediately restored first to provide adequate perfusion for the client in a shock state. Although increasing the rate of O₂ flow may be a necessary intervention, perfusion is the first priority. Obtaining arterial blood gas results and inserting an indwelling urinary catheter may be necessary interventions to monitor the client’s response to prescribed therapy, but these are not the priority.

**Test-Taking Strategy:** Note the **strategic word**, first. Although all interventions are appropriate for the client in a shock state, focus on the client’s diagnosis and think about the pathophysiology that occurs in shock, and recall that adequate perfusion is the priority.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Complex Care: Shock  
**Health Problem:** Adult Health: Cardiovascular: Shock  
**Priority Concepts:** Clinical Judgment; Perfusion  
**Reference:** Urden et al. (2018), pp. 624, 803.

868. **Answer:** 2  

**Rationale:** Shock is categorized by 4 stages. Stage 1 is characterized by restlessness, increased heart rate, cool and pale skin, and agitation. Stage 2 is characterized by a cardiac output that is less than 4 to 6 liters per minute, systolic blood pressure less than 100 mm Hg, decreased urinary output, confusion, and cerebral perfusion pressure that is less than 70 mm Hg. Stage 3 is characterized by edema, excessively low blood pressure, dysrhythmias, and weak and thready pulses. Stage 4 is characterized as unresponsiveness to vasopressors, profound hypotension, slowed heart rate, and multiple organ failure. Most often, the client will not survive.

**Test-Taking Strategy:** Note the **data in the question**, and note the word **minimally**.
Think about the stages of shock. Noting the signs of restlessness, agitation and confusion, as well as the low blood pressure and decreased urinary output, will direct you to Stage 2 as the correct answer.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Complex Care: Shock  
**Health Problem:** Adult Health: Cardiovascular: Shock  
**Priority Concepts:** Clinical Judgment; Perfusion  
**Reference:** Lewis et al. (2017), pp. 1594-1595.

869. **Answer:** 1

**Rationale:** The client in this question is likely experiencing cardiogenic shock secondary to heart failure exacerbation. It is important to note that if the shock state is cardiogenic in nature, the infusion of volume-expanding fluids may result in pulmonary edema; therefore, restoration of cardiac function is the priority for this type of shock. Cardiotonic medications such as digoxin, dopamine, or norepinephrine may be administered to increase cardiac contractility and induce vasoconstriction. Whole blood, intravenous fluids, and packed red blood cells are volume-expanding fluids and may further complicate the client’s clinical status; therefore, they should be avoided.

**Test-Taking Strategy:** Note the strategic word, priority, and focus on the subject, suspected shock in a client hospitalized for heart failure exacerbation. Recalling that this client is at risk for fluid volume overload will direct you to the correct option. Also, note that options 2, 3, and 4 are comparable or alike and involve the administration of intravenous solutions.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Complex Care: Shock  
**Health Problem:** Adult Health: Cardiovascular: Shock  
**Priority Concepts:** Clinical Judgment; Perfusion  

870. **Answer:** 3, 4, 5

**Rationale:** Sepsis diagnostic criteria with regard to signs and symptoms include the following: Fever (temperature higher than 100.9° F [38.3° C]) or hypothermia (core temperature lower than 97° F [36° C]), tachycardia (heart rate above 90 beats per minute), tachypnea (respiratory rate above 22 breaths per minute), systolic blood pressure (SBP) less than or equal to 100 mm Hg or arterial hypotension (SBP below 90 mm Hg), MAP less than 70 mm Hg, or a decrease in SBP of more than 40 mm Hg, altered mental status, edema or positive fluid balance, oliguria, ileus (absent bowel sounds), and decreased capillary refill or mottling of skin.

**Test-Taking Strategy:** Note the subject, clinical findings consistent with sepsis diagnostic criteria. Recalling that a minimum of 30 mL/hr of urine is adequate will
assist in eliminating this option. Noting that hypoactive bowel sounds are not suggestive of an ileus eliminates this option. Lastly, recalling that an SBP of 110 mm Hg does not fit the criteria will assist in eliminating this option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process — Assessment

**Content Area:** Complex Care: Sepsis

**Health Problem:** Adult Health: Cardiovascular: Shock

**Priority Concepts:** Clinical Judgment; Perfusion

UNIT XX
Comprehensive Test
Introduction

Practice Questions

871. The emergency department nurse is caring for a client who has been identified as a victim of physical abuse. In planning care for the client, which is the priority nursing action?
   1. Adhering to the mandatory abuse-reporting laws
   2. Notifying the caseworker of the family situation
   3. Removing the client from any immediate danger
   4. Obtaining treatment for the abusing family member

872. The nurse assesses a client with the admitting diagnosis of bipolar affective disorder, mania. Which client symptoms require the nurse’s immediate action?
   1. Incessant talking and sexual innuendoes
   2. Grandiose delusions and poor concentration
   3. Outlandish behaviors and inappropriate dress
   4. Nonstop physical activity and poor nutritional intake

873. The nurse is caring for a client who was involuntarily hospitalized to a mental health unit and is scheduled for electroconvulsive therapy. The nurse notes that an informed consent has not been obtained for the procedure. Based on this information, what is the nurse’s best determination in planning care?
   1. The informed consent does not need to be obtained.
   2. The informed consent should be obtained from the family.
   3. The informed consent needs to be obtained from the client.
   4. The health care provider will provide the informed consent.

874. A client newly diagnosed with diabetes mellitus is instructed by the primary health care provider to obtain glucagon for emergency home use. The client asks a home care nurse about the purpose of the medication. What is the nurse’s best response to the client’s question?
   1. “It will boost the cells in your pancreas if you have insufficient insulin.”
   2. “It will help promote insulin absorption when your glucose levels are high.”
   3. “It is for the times when your blood glucose is too low from too much insulin.”
   4. “It will help prevent lipoatrophy from the multiple insulin injections over the years.”

875. The nurse is providing care to a Puerto Rican–American client who is terminally ill. Numerous family members are present most of the time, and
many of the family members are very emotional. What is the most appropriate nursing action for this client?

1. Restrict the number of family members visiting at one time.
2. Inform the family that emotional outbursts are to be avoided.
3. Make the necessary arrangements so that family members can visit.
4. Contact the primary health care provider to speak to the family regarding their behaviors.

876. A client presents to the emergency department with upper gastrointestinal bleeding and is in moderate distress. In planning care, what is the priority nursing action for this client?

1. Assessment of vital signs
2. Completion of abdominal examination
3. Insertion of the prescribed nasogastric tube
4. Thorough investigation of precipitating events

877. The nurse is performing an assessment on a client with dementia. Which piece of data gathered during the assessment indicates a manifestation associated with dementia?

1. Use of confabulation
2. Improvement in sleeping
3. Absence of sundown syndrome
4. Presence of personal hygienic care

878. The nurse is caring for a client with anorexia nervosa. Which behavior is characteristic of this disorder and reflects anxiety management?

1. Engaging in immoral acts
2. Always reinforcing self-approval
3. Observing rigid rules and regulations
4. Having the need always to make the right decision

879. The nurse provides instructions to a malnourished pregnant client regarding iron supplementation. Which client statement indicates an understanding of the instructions?

1. “Iron supplements will give me diarrhea.”
2. “Meat does not provide iron and should be avoided.”
3. “The iron is best absorbed if taken on an empty stomach.”
4. “On the days that I eat green leafy vegetables or calf liver I can omit taking the iron supplement.”

880. Levothyroxine is prescribed for a client diagnosed with hypothyroidism. Upon review of the client’s record, the nurse notes that the client is taking warfarin. Which modification to the plan of care should the nurse review with the client’s primary health care provider?

1. A decreased dosage of levothyroxine
2. An increased dosage of levothyroxine
3. A decreased dosage of warfarin sodium
4. An increased dosage of warfarin sodium

881. The nurse is teaching a client with emphysema about positions that help breathing during dyspneic episodes. The nurse instructs the client that which positions alleviate dyspnea? Select all that apply.
1. Sitting up and leaning on a table
2. Standing and leaning against a wall
3. Lying supine with the feet elevated
4. Sitting up with the elbows resting on knees
5. Lying on the back in a low-Fowler’s position

882. A client is about to undergo a lumbar puncture. The nurse describes to the client that which position will be used during the procedure?
1. Side-lying with a pillow under the hip
2. Prone with a pillow under the abdomen
3. Prone in slight Trendelenburg’s position
4. Side-lying with the legs pulled up and the head bent down onto the chest

883. The nurse recognizes that which interventions are likely to facilitate effective communication between a dying client and family? Select all that apply.
1. The nurse encourages the client and family to identify and discuss feelings openly.
2. The nurse assists the client and family in carrying out spiritually meaningful practices.
3. The nurse removes autonomy from the client to alleviate any unnecessary stress for the client.
4. The nurse makes decisions for the client and family to relieve them of unnecessary demands.
5. The nurse maintains a calm attitude and one of acceptance when the family or client expresses anger.

884. A depressed client verbalizes feelings of low self-esteem and self-worth typified by statements such as “I’m such a failure. I can’t do anything right.” How should the nurse plan to respond to the client’s statement?
1. Reassure the client that things will get better.
2. Tell the client that this is not true and that we all have a purpose in life.
3. Identify recent behaviors or accomplishments that demonstrate the client’s skills.
4. Remain with the client and sit in silence; this will encourage the client to verbalize feelings.

885. The nurse has just admitted to the nursing unit a client with a basilar skull fracture who is at risk for increased intracranial pressure. Pending specific primary health care provider prescriptions, the nurse should safely place the client in which positions? Select all that apply.
1. Head midline
2. Neck in neutral position
3. Head of bed elevated 30 to 45 degrees
4. Head turned to the side when flat in bed
5. Neck and jaw flexed forward when opening the mouth

886. The nurse reviews the arterial blood gas results of a client with emphysema and notes that the laboratory report indicates a pH of 7.30, PaCO\(_2\) of 58 mm Hg, PaO\(_2\) of 80 mm Hg, and HCO\(_3\) of 27 mEq/L (27 mmol/L). The nurse interprets that the client has which acid–base disturbance?
   1. Metabolic acidosis
   2. Metabolic alkalosis
   3. Respiratory acidosis
   4. Respiratory alkalosis

887. The nurse has admitted a client to the clinical nursing unit after undergoing a right mastectomy. The nurse should plan to place the right arm in which position?
   1. Elevated on a pillow
   2. Level with the right atrium
   3. Dependent to the right atrium
   4. Elevated above shoulder level

888. On the second postpartum day, a client complains of burning on urination, urgency, and frequency of urination. A urinalysis indicates the presence of a urinary tract infection. The nurse instructs the client regarding measures to take for the treatment of the infection. Which client statement indicates to the nurse the need for further instruction?
   1. “I need to urinate frequently throughout the day.”
   2. “The prescribed medication must be taken until it is finished.”
   3. “My fluid intake should be increased to at least 3000 mL daily.”
   4. “Foods and fluids that will increase urine alkalinity should be consumed.”

889. A client received 20 units of Humulin N insulin subcutaneously at 08:00. At what time should the nurse plan to assess the client for a hypoglycemic reaction?
   1. 10:00
   2. 11:00
   3. 17:00
   4. 24:00

890. The nurse is the first responder after a tornado has destroyed many homes in the community. Which victim should the nurse attend to first?
   1. A pregnant woman who exclaims, “My baby is not moving.”
   2. A woman who is complaining, “My leg is bleeding so bad, I am afraid it is going to fall off!”
   3. A young child standing next to an adult family member who is screaming, “I want my mommy!”
   4. An older victim who is sitting next to her husband sobbing, “My husband is dead. My husband is dead.”

891. A pregnant client at 10 weeks’ gestation calls the prenatal clinic to report a recent exposure to a child with rubella. The nurse reviews the client’s chart.
What is the nurse’s best response to the client? Refer to chart.

1. “You should avoid all school-age children during pregnancy.”
2. “There is no need to be concerned if you don’t have a fever or rash within the next 2 days.”
3. “You were wise to call. Your rubella titer indicates that you are immune and your baby is not at risk.”
4. “Be sure to tell the primary health care provider in 2 weeks, as additional screening will be prescribed during your second trimester.”

892. A breast-feeding mother of an infant with lactose intolerance asks the nurse about dietary measures. What foods should the nurse tell the mother are acceptable to consume while breast-feeding? Select all that apply.

- [ ] 1. 1% milk
- [ ] 2. Egg yolk
- [ ] 3. Dried beans
- [ ] 4. Hard cheeses
- [ ] 5. Green leafy vegetables

893. A client with diabetes mellitus is told that amputation of the leg is necessary to sustain life. The client is very upset and tells the nurse, “This is all my primary health care provider’s fault. I have done everything I’ve been asked to do!” Which nursing interpretation is best for this situation?

1. An expected coping mechanism
2. An ineffective defense mechanism
3. A need to notify the hospital lawyer
4. An expression of guilt on the part of the client

894. A client with terminal cancer arrives at the emergency department dead on arrival (DOA). After an autopsy is prescribed, the client’s family requests that no autopsy be performed. Which response to the family is most appropriate?

1. “The decision is made by the medical examiner.”
2. “An autopsy is mandatory for any client who is DOA.”
3. “I will contact the medical examiner regarding your request.”
4. “It is required by federal law. Tell me why you don’t want the autopsy done.”

895. A client who is positive for human immunodeficiency virus (HIV) delivers a newborn infant. The nurse provides instructions to help the client with care of her infant. Which client statement indicates the need for further instruction?
1. “I will be sure to wash my hands before and after bathroom use.”
2. “I need to breast-feed, especially for the first 6 weeks postpartum.”
3. “Support groups are available to assist me with understanding my diagnosis of HIV.”
4. “My newborn infant should be on antiviral medications for the first 6 weeks after delivery.”

896. An adolescent client is diagnosed with conjunctivitis, and the nurse provides information to the client about the use of contact lenses. Which client statement indicates the need for further information?
1. “I should obtain new contact lenses.”
2. “I should not wear my contact lenses.”
3. “My old contact lenses should be discarded.”
4. “My contact lenses can be worn if they are cleaned as directed.”

897. The nurse teaches a client newly diagnosed with type 1 diabetes about storing Humulin N insulin. Which statement indicates to the nurse that the client understood the discharge teaching?
1. “I should keep the insulin in the cabinet during the day only.”
2. “I know I have to keep my insulin in the refrigerator at all times.”
3. “I can store the open insulin bottle in the kitchen cabinet for 1 month.”
4. “The best place for my insulin is on the windowsill, but in the cupboard is just as good.”

898. The nurse is caring for a client scheduled for a transsphenoidal hypophysectomy. The preoperative teaching instructions should include which statement?
1. “Your hair will need to be shaved.”
2. “You will receive spinal anesthesia.”
3. “You will need to ambulate after surgery.”
4. “Brushing your teeth needs to be avoided for at least 2 weeks after surgery.”

899. During a routine prenatal visit, a client complains of gums that bleed easily with brushing. The nurse performs an assessment and teaches the client about proper nutrition to minimize this problem. Which client statement indicates an understanding of the proper nutrition to minimize this problem?
1. “I will drink 8 oz of water with each meal.”
2. “I will eat 3 servings of cracked wheat bread each day.”
3. “I will eat 2 saltine crackers before I get up each morning.”
4. “I will eat fresh fruits and vegetables for snacks and for dessert each day.”

900. A 6-year-old child has just been diagnosed with localized Hodgkin’s disease, and chemotherapy is planned to begin immediately. The mother of the child asks the nurse why radiation therapy was not prescribed as a part of the treatment. What is the nurse’s best response?
1. “It’s very costly, and chemotherapy works just as well.”
2. “I’m not sure. I’ll discuss it with the primary health care provider.”
3. “Sometimes age has to do with the decision for radiation
therapy."
4. “The primary health care provider would prefer that you discuss treatment options with the oncologist.”

901. An infant born with an imperforate anus returns from surgery after requiring a colostomy. The nurse assesses the stoma and notes that it is red and edematous. Based on this finding, which action should the nurse take?
1. Elevate the buttocks.
2. Document the findings.
3. Apply ice immediately.
4. Call the primary health care provider.

902. The nurse is performing an initial assessment on a newborn infant. When assessing the infant’s head, the nurse notes that the ears are low-set. Which nursing action is most appropriate?
1. Document the findings.
2. Arrange for hearing testing.
3. Notify the pediatrician.
4. Cover the ears with gauze pads.

903. The clinic nurse is assessing jaundice in a child with hepatitis. Which anatomical area would provide the best data regarding the presence of jaundice?
1. The nail beds
2. The skin in the sacral area
3. The skin in the abdominal area
4. The membranes in the ear canal

904. The nurse is assigned to care for a client in traction. The nurse creates a plan of care for the client and should include which action in the plan?
1. Ensure that the knots are at the pulleys.
2. Check the weights to ensure that they are off of the floor.
3. Ensure that the head of the bed is kept at a 45- to 90-degree angle.
4. Monitor the weights to ensure that they are resting on a firm surface.

905. The nurse is setting up the physical environment for an interview with a client and plans to obtain subjective data regarding the client’s health. Which interventions are appropriate? Select all that apply.

1. Set the room temperature at a comfortable level.
2. Remove distracting objects from the interviewing area.
3. Place a chair for the client across from the nurse’s desk.
4. Ensure comfortable seating at eye level for the client and nurse.
5. Provide seating for the client so that the client faces a strong light.
6. Ensure that the distance between the client and nurse is at least 7 feet (2.1 meters).

906. The nurse is caring for an older adult who has been placed in Buck’s
extension traction after a hip fracture. On assessment of the client, the nurse notes that the client is disoriented. What is the best nursing action based on this information?
   1. Apply restraints to the client.
   2. Ask the family to stay with the client.
   3. Place a clock and calendar in the client’s room.
   4. Ask the laboratory to perform electrolyte studies.

907. The nurse is creating a plan of care for a client in skin traction. The nurse should monitor for which priority finding in this client?
   1. Urinary incontinence
   2. Signs of skin breakdown
   3. The presence of bowel sounds
   4. Signs of infection around the pin sites

908. The home care nurse is visiting a client who is in a body cast. While performing an assessment, the nurse plans to evaluate the psychosocial adjustment of the client to the cast. What is the most appropriate assessment for this client?
   1. The need for sensory stimulation
   2. The amount of home care support available
   3. The ability to perform activities of daily living
   4. The type of transportation available for follow-up care

909. What action should the nurse consider when counseling a client of the Amish tradition?
   1. Speak only to the husband.
   2. Use complex medical terminology.
   3. Avoid using scientific or medical jargon.
   4. Stand close to the client and speak loudly.

910. A client has refused to eat more than a few spoonfuls of breakfast. The primary health care provider has prescribed that tube feedings be initiated if the client fails to eat at least half of a meal because the client has lost a significant amount of weight during the previous 2 months. The nurse enters the room, looks at the tray, and states, “If you don’t eat any more than that, I’m going to have to put a tube down your throat and get a feeding in that way.” The client begins crying and tries to eat more. Based on the nurse’s actions, the nurse may be accused of which violation?
   1. Assault
   2. Battery
   3. Slander
   4. Invasion of privacy

911. When creating an assignment for a team consisting of a registered nurse (RN), 1 licensed practical nurse (LPN), and 2 assistive personnel (AP), which is the best client for the LPN?
   1. A client requiring frequent temperature checks
   2. A client requiring assistance with ambulation every 4 hours
   3. A client on a mechanical ventilator requiring frequent assessment and suctioning
   4. A client with a spinal cord injury requiring urinary catheterization every 6 hours

2580
912. To perform cardiopulmonary resuscitation (CPR), the nurse should use the method pictured to open the airway in which situation? Refer to figure.

1. If neck trauma is suspected
2. In all situations requiring CPR
3. If the client has a history of seizures
4. If the client has a history of headaches

913. The nurse teaches skin care to a client receiving external radiation therapy. Which client statement indicates the need for further instruction?

1. “I will handle the area gently.”
2. “I will wear loose-fitting clothing.”
3. “I will avoid the use of deodorants.”
4. “I will limit sun exposure to 1 hour daily.”

914. The primary health care provider’s prescription reads levothyroxine, 150 mcg orally daily. The medication label reads levothyroxine, 0.1 mg per tablet. The nurse should administer how many tablet(s) to the client? Fill in the blank.

Answer: _____ tablet(s)

915. Metformin is prescribed for a client with type 2 diabetes mellitus. What is the most common side effect that the nurse should include in the client’s teaching plan?

1. Weight gain
2. Hypoglycemia
3. Flushing and palpitations
4. Gastrointestinal disturbances

916. Which nursing actions apply to the care of a child who is having a seizure? Select all that apply.

☐ 1. Time the seizure.
☐ 2. Restrain the child.
3. Stay with the child.
4. Insert an oral airway.
5. Loosen clothing around the child’s neck.
6. Place the child in a lateral side-lying position.

917. The nurse is conducting an interview of an older client and is concerned about the possibility of benign prostatic hyperplasia (BPH). Which are characteristics of this disorder? Select all that apply.

☐ 1. Nocturia
☐ 2. Incontinence
☐ 3. Enlarged prostate
☐ 4. Nocturnal emissions
☐ 5. Decreased desire for sexual intercourse

918. The nursing instructor asks a nursing student to identify the priorities of care for an assigned client. Which statement indicates that the student correctly identifies the priority client needs?

1. Actual or life-threatening concerns
2. Completing care in a reasonable time frame
3. Time constraints related to the client’s needs
4. Obtaining needed supplies to care for the client

919. A client arrives at the clinic complaining of fatigue, lack of energy, constipation, and depression. Hypothyroidism is diagnosed, and levothyroxine is prescribed. What is an expected outcome of the medication?

1. Alleviate depression
2. Increase energy levels
3. Increase blood glucose levels
4. Achieve normal thyroid hormone levels

920. The community health nurse is creating a poster for an educational session for a group of women and will be discussing the risk factors associated with breast cancer. Which risk factors for breast cancer should the nurse list on the poster? Select all that apply.

☐ 1. Multiparity
☐ 2. Early menarche
☐ 3. Early menopause
☐ 4. Family history of breast cancer
☐ 5. High-dose radiation exposure to chest
☐ 6. Previous cancer of the breast, uterus, or ovaries

921. The nurse is caring for a client with acute pancreatitis and is monitoring the client for paralytic ileus. Which piece of assessment data should alert the nurse to this occurrence?
1. Inability to pass flatus
2. Loss of anal sphincter control
3. Severe, constant pain with rapid onset
4. Firm, nontender mass palpable at the lower right costal margin

922. The nurse inspects the color of the drainage from a nasogastric tube on a postoperative client approximately 24 hours after gastric surgery. Which finding indicates the need to notify the primary health care provider (PHCP)?
   1. Dark red drainage
   2. Dark brown drainage
   3. Green-tinged drainage
   4. Light yellowish-brown drainage

923. The nurse is preparing to discontinue a client’s nasogastric tube. The client is positioned properly, and the tube has been flushed with 15 mL of air to clear secretions. Before removing the tube, the nurse should make which statement to the client?
   1. “Take a deep breath when I tell you, and hold it while I remove the tube.”
   2. “Take a deep breath when I tell you, and bear down while I remove the tube.”
   3. “Take a deep breath when I tell you, and slowly exhale while I remove the tube.”
   4. “Take a deep breath when I tell you, and breathe normally while I remove the tube.”

924. A client with a history of lung disease is at risk for developing respiratory acidosis. The nurse should assess the client for which signs and symptoms characteristic of this disorder?
   1. Bradycardia and hyperactivity
   2. Decreased respiratory rate and depth
   3. Headache, restlessness, and confusion
   4. Bradypnea, dizziness, and paresthesias

925. The nurse is caring for a client with a resolved intestinal obstruction who has a nasogastric tube in place. The primary health care provider has now prescribed that the nasogastric tube be removed. What is the priority nursing assessment prior to removing the tube?
   1. Checking for normal serum electrolyte levels
   2. Checking for normal pH of the gastric aspirate
   3. Checking for proper nasogastric tube placement
   4. Checking for the presence of bowel sounds in all 4 quadrants

926. The nurse has reviewed with the preoperative client the procedure for the administration of an enema. Which statement by the client would indicate the need for further instruction?
   1. “The enema will be given while I am sitting on the toilet.”
   2. “I should try and hold the fluid as long as possible after it is run in.”
   3. “I know that there will be some cramping after the enema solution is run in.”
   4. “I should tell the nurse if cramping occurs when the fluid is
running in.”

927. A client experiencing a great deal of stress and anxiety is being taught to use self-control therapy. Which statement by the client indicates a need for further teaching about the therapy?

1. “This form of therapy can be applied to new situations.”
2. “An advantage of this technique is that change is likely to last.”
3. “Talking to oneself is a basic component of this form of therapy.”
4. “This form of therapy provides a negative reinforcement when the stimulus is produced.”

928. The nurse is preparing a list of home care instructions regarding stoma and laryngectomy care for a client with laryngeal cancer who had a laryngectomy. Which instructions should be included in the list? Select all that apply.

1. Restrict fluid intake.
2. Obtain a MedicAlert bracelet.
3. Keep the humidity in the home low.
4. Prevent debris from entering the stoma.
5. Avoid exposure to people with infections.
6. Avoid swimming and use care when showering.

929. The primary health care provider prescribes 2000 mL of 5% dextrose and half-normal saline to infuse over 24 hours. The drop factor is 15 drops (gtt)/mL. The nurse should set the flow rate at how many drops per minute? Fill in the blank. Record your answer to the nearest whole number.

Answer: _____ gtt/minute

930. A client is returned to the nursing unit after thoracic surgery with chest tubes in place. During the first few hours postoperatively, what type of drainage should the nurse expect?

1. Serous
2. Bloody
3. Serosanguineous
4. Bloody, with frequent small clots

931. A client has had radical neck dissection and begins to hemorrhage at the incision site. The nurse should take which actions in this situation? Select all that apply.

1. Monitor vital signs.
2. Monitor the client’s airway.
3. Apply manual pressure over the site.
4. Lower the head of the bed to a flat position.
5. Call the primary health care provider (PHCP) immediately.

932. A sexually active young adult client has developed viral hepatitis. Which client statement indicates the need for further teaching? Select all that apply.

1. “I should avoid drinking alcohol.”
2. “I can go back to work right away.”
3. “My partner should get the vaccine.”
4. “A condom should be used for sexual intercourse.”

933. The nurse should include which interventions in the plan of care for a client with hypothyroidism? **Select all that apply.**

- [ ] 1. Provide a cool environment for the client.
- [ ] 2. Instruct the client to consume a high-fat diet.
- [ ] 3. Instruct the client about thyroid replacement therapy.
- [ ] 4. Encourage the client to consume fluids and high-fiber foods in the diet.
- [ ] 5. Inform the client that iodine preparations will be prescribed to treat the disorder.
- [ ] 6. Instruct the client to contact the primary health care provider (PHCP) if episodes of chest pain occur.

934. The nurse is preparing to care for a client who will be weaned from a cuffed tracheostomy tube. The nurse is planning to use a tracheostomy plug and plans to insert it into the opening in the outer cannula. Which nursing action is required before plugging the tube?

1. Deflate the cuff on the tube.
2. Place the inner cannula into the tube.
3. Ensure that the client is able to speak.
4. Ensure that the client is able to swallow.

935. A client is diagnosed with glaucoma. Which piece of nursing assessment data identifies a risk factor associated with this eye disorder?

- [ ] 1. Cardiovascular disease
- [ ] 2. Frequent urinary tract infections
- [ ] 3. A history of migraine headaches
- [ ] 4. Frequent upper respiratory infections

936. A client with retinal detachment is admitted to the nursing unit in preparation for a repair procedure. Which prescription should the nurse anticipate?

1. Allowing bathroom privileges only
2. Elevating the head of the bed to 45 degrees
3. Wearing dark glasses to read or watch television
4. Placing an eye patch over the client’s affected eye

937. The nurse is caring for a client who is on strict bed rest and creates a plan of care with goals related to the prevention of deep vein thrombosis and pulmonary emboli. Which nursing action is most helpful in preventing these disorders from developing?

1. Restricting fluids
2. Placing a pillow under the knees
3. Encouraging active range-of-motion exercises
4. Applying a heating pad to the lower extremities

938. The nurse is caring for a client who is at risk for suicide. What is the priority
nursing action for this client?
1. Provide authority, action, and participation.
2. Display an attitude of detachment, confrontation, and efficiency.
3. Demonstrate confidence in the client’s ability to deal with stressors.
4. Provide hope and reassurance that the problems will resolve themselves.

939. A client with tuberculosis whose status is being monitored in an ambulatory care clinic asks the nurse when it is permissible to return to work. What factor should the nurse include when responding to the client?
1. Five blood cultures are negative.
2. Three sputum cultures are negative.
3. A blood culture and a chest x-ray are negative.
4. A sputum culture and a tuberculin skin test are negative.

940. A client comes to the emergency department after an assault and is extremely agitated, trembling, and hyperventilating. What is the priority nursing action for this client?
1. Begin to teach relaxation techniques.
2. Encourage the client to discuss the assault.
3. Remain with the client until the anxiety decreases.
4. Place the client in a quiet room alone to decrease stimulation.

941. The nurse is caring for a client admitted to the hospital with a suspected diagnosis of acute appendicitis. Which laboratory result should the nurse expect to note if the client does have appendicitis?
1. Leukopenia with a shift to the left
2. Leukocytosis with a shift to the left
3. Leukopenia with a shift to the right
4. Leukocytosis with a shift to the right

942. The nurse is creating a plan of care for a client who was experiencing anxiety after the loss of a job. The client is now verbalizing concerns regarding the ability to meet role expectations and financial obligations. What is the priority nursing problem for this client?
1. Anxiety
2. Unrealistic outlook
3. Lack of ability to cope effectively
4. Disturbances in thoughts and ideas

943. The nurse is monitoring the chest tube drainage system in a client with a chest tube. The nurse notes intermittent bubbling in the water seal chamber. Which is the most appropriate nursing action?
1. Check for an air leak.
2. Document the findings.
3. Notify the primary health care provider.
4. Change the chest tube drainage system.

944. After performing an initial abdominal assessment on a client with nausea and vomiting, the nurse should expect to note which finding?
1. Waves of loud gurgles auscultated in all 4 quadrants
2. Low-pitched swishing auscultated in 1 or 2 quadrants
3. Relatively high-pitched clicks or gurgles auscultated in all 4
4. Very high-pitched, loud rushes auscultated especially in 1 or 2 quadrants

945. The primary health care provider prescribes erythromycin suspension 800 mg by mouth. After reconstitution, how many milliliters should the nurse pour into the medicine cup to deliver the prescribed dose? Refer to figure. Fill in the blank.

Answer: _____ mL

Answers

871. Answer: 3

**Rationale:** Whenever an abused client remains in the abusive environment, priority must be placed on ascertaining whether the client is in any immediate danger. If so, emergency action must be taken to remove the client from the abusing situation. Options 1, 2, and 4 may be appropriate interventions but are not the priority.

**Test-Taking Strategy:** Note the strategic word, *priority.* Use **Maslow’s Hierarchy of Needs theory**, remembering that if a physiological need is not present, safety is the priority. This will direct you to the correct option, the only one that directly addresses client safety.

**Level of Cognitive Ability:** Applying

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Planning

**Content Area:** Mental Health

**Health Problem:** Mental Health: Abusive behaviors

**Priority Concepts:** Interpersonal Violence; Safety

872. Answer: 4

**Rationale:** Mania is a mood characterized by excitement, euphoria, hyperactivity, excessive energy, decreased need for sleep, and impaired ability to concentrate or complete a single train of thought. The client’s mood is predominantly elevated, expansive, or irritable. All of the options reflect a client’s possible symptoms. However, the correct option clearly presents a problem that compromises physiological integrity and needs to be addressed immediately.

**Test-Taking Strategy:** Note the strategic word, immediate, and use Maslow’s Hierarchy of Needs theory to assist you in answering the question. The correct option is the only one that reflects a physiological need.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process — Assessment

**Content Area:** Mental Health

**Health Problem:** Mental Health: Mood disorders

**Priority Concepts:** Psychosis; Safety

873. Answer: 3

**Rationale:** Clients who are admitted involuntarily to a mental health unit do not lose their right to informed consent. Clients must be considered legally competent until they have been declared incompetent through a legal proceeding. The best determination for the nurse to make is to obtain the informed consent from the client.

**Test-Taking Strategy:** Focus on the subject, informed consent for an involuntarily admitted client, and note the strategic word, best. Knowledge regarding the hospital admission processes and client’s rights will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process — Planning

**Content Area:** Leadership/Management: Ethical/Legal

**Health Problem:** Mental Health: Mood disorders

**Priority Concepts:** Ethics; Health Care Law

874. Answer: 3

**Rationale:** Glucagon is used to treat hypoglycemia resulting from insulin overdose. The family of the client is instructed in how to administer the medication. In an unconscious client, arousal usually occurs within 20 minutes of glucagon injection. When consciousness has been regained, oral carbohydrates should be given. Lipoatrophy and lipohypertrophy result from insulin injections.

**Test-Taking Strategy:** Focus on the subject, the purpose of glucagon. Also note the strategic word, best. Noting the word glucagon will assist you in determining that the medication contains some form of glucose. This relationship will direct you...
to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Adult Health: Endocrine

**Health Problem:** Adult Health: Endocrine: Diabetes mellitus

**Priority Concepts:** Client Education; Glucose Regulation

875. **Answer:** 3

**Rationale:** In the Puerto Rican–American culture, loud crying and other physical manifestations of grief are considered socially acceptable. Of the options provided, the correct option is the only one that identifies a culturally sensitive approach on the part of the nurse. Options 1, 2, and 4 are inappropriate nursing interventions.

**Test-Taking Strategy:** Note the **strategic word**, **most appropriate**. Focus on the clients of the question, the family members. Use therapeutic nursing interventions, recalling the characteristics of the culture and the importance of cultural sensitivity. This will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Culture and Spirituality

**Content Area:** Foundations of Care: Spirituality, culture, ethnicity

**Health Problem:** Mental Health: Grief/Loss

**Priority Concepts:** Culture; Family Dynamics

**Reference:** Lewis et al. (2017), pp. 25, 30.

876. **Answer:** 1

**Rationale:** The priority nursing action is to assess the vital signs. This would provide information about the amount of blood loss that has occurred and provide a baseline by which to monitor the progress of treatment. The client may be unable to provide subjective data until the immediate physical needs are met. Although an abdominal examination and an assessment of the precipitating events may be necessary, these actions are not the priority. Insertion of a nasogastric tube is not the priority and will require a primary health care provider’s prescription; in addition, the vital signs should be checked before performing this procedure.

**Test-Taking Strategy:** Note the **strategic word**, **priority**, and use the **ABCs**—airway, breathing, circulation. This will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Complex Care: Emergency Situations/Management

**Health Problem:** Adult Health: Gastrointestinal: Upper GI disorders

**Priority Concepts:** Care Coordination; Clinical Judgment

**Reference:** Lewis et al. (2017), p. 924.
877. **Answer:** 1

**Rationale:** The clinical picture of dementia ranges from mild cognitive deficits to severe, life-threatening alterations in neurological functioning. For the client to use confabulation or the fabrication of events or experiences to fill in memory gaps is not unusual. Often, lack of inhibitions on the part of the client may constitute the first indication of something being “wrong” to the client’s significant others (e.g., the client may undress in front of others, or the formerly well-mannered client may exhibit slovenly table manners). As the dementia progresses, the client will have difficulty sleeping and episodes of wandering or sundowning.

**Test-Taking Strategy:** Focus on the client’s diagnosis and note the subject, a manifestation of dementia. Think about the characteristics of dementia to direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Mental Health

**Health Problem:** Mental Health: Neurocognitive impairment

**Priority Concepts:** Cognition; Coping

878. **Answer:** 3

**Rationale:** Clients with anorexia nervosa have the desire to please others. Their need to be correct or perfect interferes with rational decision-making processes. These clients are moralistic. Rules and rituals help these clients manage their anxiety.

**Test-Taking Strategy:** Focus on the subject, managing anxiety. Eliminate options 2 and 4 because of the closed-ended word “always.” Option 1 is not characteristic of a client with anorexia.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Mental Health

**Health Problem:** Mental Health: Eating disorders

**Priority Concepts:** Anxiety; Coping

**Reference:** Lewis et al. (2017), pp. 871-872.

879. **Answer:** 3

**Rationale:** Iron is needed to allow for transfer of adequate iron to the fetus and to permit expansion of the maternal red blood cell mass. During pregnancy, the relative excess of plasma causes a decrease in the hemoglobin concentration and hematocrit, known as physiological anemia of pregnancy. This is a normal adaptation during pregnancy. Iron is best absorbed if taken on an empty stomach. Taking it with a fluid high in ascorbic acid such as tomato juice enhances absorption. Iron supplements usually cause constipation. Meats are an excellent source of iron. The client needs to take the iron supplements regardless of food intake.
**Test-Taking Strategy:** Note the **subject**, iron supplementation during pregnancy. Focus on the words *understanding of the instructions*. Knowledge of basic principles related to nutrition during pregnancy will assist in eliminating options 2 and 4. From the remaining options, remember that iron causes constipation.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Evaluation  
**Content Area:** Maternity: Antepartum  
**Health Problem:** Adult Health: Gastrointestinal: Nutrition Problems  
**Priority Concepts:** Client Education; Nutrition  
**Reference:** McKinney et al. (2018), p. 266.

880. **Answer:** 3

**Rationale:** Levothyroxine accelerates the degradation of vitamin K–dependent clotting factors. As a result, the effects of warfarin are enhanced. If thyroid hormone replacement therapy is instituted in a client who has been taking warfarin, the dosage of warfarin should be reduced.

**Test-Taking Strategy:** Focus on the **subject**, the use of levothyroxine concurrently with warfarin. Recalling that levothyroxine enhances the effects of warfarin will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Analysis  
**Content Area:** Pharmacology: Endocrine Medications: Thyroid hormones  
**Health Problem:** Adult Health: Endocrine: Thyroid disorders  
**Priority Concepts:** Collaboration; Safety  

881. **Answer:** 1, 2, 4

**Rationale:** The client should use the positions outlined in options 1, 2, and 4. These allow for maximal chest expansion. The client should not lie on the back because this reduces movement of a large area of the client’s chest wall. Sitting is better than standing, whenever possible. If no chair is available, leaning against a wall while standing allows accessory muscles to be used for breathing and not posture control.

**Test-Taking Strategy:** Focus on the **subject**, the positions that could alleviate dyspnea. Remember that upright positions are best. Also, note that options 1, 2, and 4 are comparable or alike in that they all address upright positions.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Respiratory  
**Health Problem:** Adult Health: Respiratory: Obstructive pulmonary disease  
**Priority Concepts:** Client Education; Gas Exchange  
882. **Answer:** 4

**Rationale:** A client undergoing lumbar puncture is positioned lying on the side, with the legs pulled up to the abdomen and the head bent down onto the chest. This position helps open the spaces between the vertebrae and allows for easier needle insertion by the primary health care provider. The nurse remains with the client during the procedure to help the client maintain this position. The other options identify incorrect positions for this procedure.

**Test-Taking Strategy:** Focus on the subject, lumbar puncture. Recalling that a lumbar puncture is the introduction of a needle into the subarachnoid space will direct you to the correct option. It is reasonable that the position of the client must facilitate this, and the correct option is the only position that flexes the vertebrae and widens the spaces between them.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Foundations of Care: Diagnostic Tests

**Health Problem:** N/A

**Priority Concepts:** Intracranial Regulation; Safety

883. **Answer:** 1, 2, 5

**Rationale:** Maintaining effective and open communication among family members affected by death and grief is of the greatest importance. Option 1 describes encouraging discussion of feelings and is likely to enhance communication. Option 2 is also an effective intervention because spiritual practices give meaning to life and have an impact on how people react to crisis. Option 5 is also an effective technique because the client and family need to know that someone will be there who is supportive and nonjudgmental. The remaining options describe the nurse removing autonomy and decision making from the client and family, who are already experiencing feelings of loss of control in that they cannot change the process of dying. These are ineffective interventions that could impair communication further.

**Test-Taking Strategy:** Focus on the subject, the interventions that will facilitate effective communication. Use of therapeutic communication techniques and focusing on the subject will assist you in answering correctly. The incorrect options remove control from the client and family.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Caring

**Content Area:** Developmental Stages: End-of-Life Care

**Health Problem:** Mental Health: Grief/Loss

**Priority Concepts:** Caregiving; Family Dynamics

**Reference:** Potter et al. (2017), pp. 763-764.

884. **Answer:** 3
**Rationale:** Feelings of low self-esteem and worthlessness are common symptoms of a depressed client. An effective plan of care to enhance the client’s personal self-esteem is to provide experiences for the client that are challenging but that will not be met with failure. Reminders of the client’s past accomplishments or personal successes are ways to interrupt the client’s negative self-talk and distorted cognitive view of self. Options 1 and 2 give advice and devalue the client’s feelings. Silence may be interpreted as agreement.

**Test-Taking Strategy:** Use therapeutic communication techniques and focus on the client’s diagnosis. You can eliminate options 1 and 2 easily because they are nontherapeutic. From the remaining options, focusing on the client’s diagnosis will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Psychosocial Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Mental Health

**Health Problem:** Mental Health: Mood disorders

**Priority Concepts:** Caregiving; Mood and Affect

885. **Answer:** 1, 2, 3

**Rationale:** Use of proper positions promotes venous drainage from the cranium to keep intracranial pressure from elevating. The head of the client at risk for or with increased intracranial pressure should be positioned so that it is in a neutral, midline position. The head of the bed should be raised to 30 to 45 degrees. The nurse should avoid flexing or extending the client’s neck or turning the client’s head from side to side.

**Test-Taking Strategy:** Focus on the subject, care of the client with increased intracranial pressure. Visualize each of the positions identified in the options and identify those that will promote venous drainage from the cranium.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Adult Health: Neurological

**Health Problem:** Adult Health: Neurological: Head injury/trauma

**Priority Concepts:** Intracranial Regulation; Safety

886. **Answer:** 3

**Rationale:** The normal pH is 7.35 to 7.45. Normal PaCO\(_2\) is 35 to 45 mm Hg. In respiratory acidosis, the pH is low and PaCO\(_2\) is elevated. Options 1, 2, and 4 are incorrect interpretations of the values identified in the question.

**Test-Taking Strategy:** Focus on the subject, interpretation of arterial blood gas levels. Remember that in a respiratory imbalance you will find an opposite response between the pH and PaCO\(_2\). Also, remember that the pH is low in an acidotic condition. Recalling this information will allow you to eliminate each of the incorrect
options.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Analysis  
**Content Area:** Foundations of Care: Acid–base  
**Health Problem:** Adult Health: Respiratory: Obstructive Pulmonary Disease  
**Priority Concepts:** Acid–base Balance; Clinical Judgment  
**Reference:** Lewis et al. (2017), pp. 291, 457.

887. **Answer:** 1

**Rationale:** The client’s operative arm should be positioned so that it is elevated on a pillow and not exceeding shoulder elevation. This position promotes optimal drainage from the limb, without impairing the circulation to the arm. If the arm is positioned flat (option 2) or dependent (option 3), this could increase the edema in the arm, which is contraindicated because of lymphatic disruption caused by surgery.

**Test-Taking Strategy:** Focus on the subject, care of the client following mastectomy. Read each option carefully and attempt to visualize the position identified in the option. Using the principles of circulation and gravity will direct you to the correct option. The correct option avoids the two extremes of height (dependent, above shoulder level) in positioning the limb affected by surgery.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Adult Health: Oncology  
**Health Problem:** Adult Health: Cancer: Breast  
**Priority Concepts:** Perfusion; Tissue Integrity  

888. **Answer:** 4

**Rationale:** A client with a urinary tract infection must be encouraged to take the prescribed medication for the entire time it is prescribed. The client should also be instructed to drink at least 3000 mL of fluid each day to flush the infection from the bladder and to urinate frequently throughout the day. Foods and fluids that acidify the urine need to be encouraged.

**Test-Taking Strategy:** Note the strategic words, need for further instruction. These words indicate a negative event query and ask you to select an option that is incorrect. Recall that foods and fluids that acidify the urine should be consumed, rather than foods and fluids that cause urine alkalinity.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Maternity: Postpartum  
**Health Problem:** Adult Health: Renal and Urinary: Inflammation/Infections  
**Priority Concepts:** Client Education; Infection

889. Answer: 3

Rationale: Humulin N is an intermediate-acting insulin. The onset of action is 60 to 120 minutes, it peaks in 6 to 14 hours, and the duration of action is 16 to 24 hours. Hypoglycemic reactions most likely occur during peak time.

Test-Taking Strategy: Focus on the subject, characteristics of Humulin N insulin, and use knowledge regarding the onset, peak, and duration of action. Recalling that it is an intermediate-acting insulin and recalling that peak action is between 6 and 14 hours will direct you to the correct option.

Level of Cognitive Ability: Applying
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Planning
Content Area: Pharmacology: Endocrine Medications: Insulin
Health Problem: Adult Health: Endocrine: Diabetes mellitus
Priority Concepts: Glucose Regulation; Safety

890. Answer: 2

Rationale: Priority nursing care in disaster situations needs to be delivered to the living and not the dead. The victim who is bleeding badly is the priority. The bleeding could be from an arterial vessel; if the bleeding is not stopped, the victim is at risk for shock and death. The pregnant client is the next priority, but the absence of fetal movement may or may not be indicative of fetal demise. The young child is with a family member and is safe at this time. The older victim will need comfort measures; there is no information indicating she is physically hurt.

Test-Taking Strategy: Note the strategic word, first. Use Maslow’s Hierarchy of Needs theory when answering this question. Remember that physical needs should be addressed before psychosocial needs and use the ABCs—airway, breathing, and circulation. Bleeding is the priority.

Level of Cognitive Ability: Synthesizing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Leadership/Management: Mass Causality Preparedness and Response
Health Problem: Adult Health: Cardiovascular: Shock
Priority Concepts: Care Coordination; Clinical Judgment

891. Answer: 3

Rationale: Rubella virus is spread by aerosol droplet transmission through the upper respiratory tract and has an incubation period of 14 to 21 days. The risks of maternal and subsequent fetal infection during the second trimester include hearing loss and congenital anomalies; these risks decrease after the first 12 weeks of
pregnancy. Rubella titer determination is a standard prenatal test for pregnant women during their initial screening and entry into the health care delivery system. As noted in this client’s chart, she is immune to rubella. The correct option is the only option that helps clarify maternal concerns with accurate information.

**Test-Taking Strategy:** Note the **strategic word**, best, and recall knowledge regarding the transmission of rubella virus to the fetus. Also, use of **therapeutic communication techniques** will direct you to the correct option. The correct option addresses the client’s concerns.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Caring  
**Content Area:** Maternity: Antepartum  
**Health Problem:** Maternity: Infections/Inflammations  
**Priority Concepts:** Immunity; Safety  
**Reference:** Lowdermilk et al. (2016), p. 166.

892. **Answer:** 2, 3, 5

**Rationale:** Breast-feeding mothers with lactose-intolerant infants need to be encouraged to limit dairy products. Milk and cheese are dairy products. Alternative calcium sources that can be consumed by the mother include egg yolk, dried beans, green leafy vegetables, cauliflower, and molasses.

**Test-Taking Strategy:** Focus on the **subject**, foods acceptable for a breast-feeding mother with a lactose-intolerant infant. Recall that lactose is the sugar found in dairy products. Also note that options 1 and 4 are **comparable or alike** and are dairy products.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Foundations of Care: Nutrition  
**Health Problem:** Newborn: Newborn feeding  
**Priority Concepts:** Client Education; Nutrition  

893. **Answer:** 1

**Rationale:** The nurse needs to be aware of the effective and ineffective coping mechanisms that can occur in a client when loss is anticipated. The expression of anger is known to be a normal response to impending loss, and the anger may be directed toward the self, God or other spiritual being, or caregivers. Notifying the hospital lawyer is inappropriate. Guilt may or may not be a component of the client’s feelings, and the data in the question do not indicate that guilt is present.

**Test-Taking Strategy:** Note the **subject**, psychosocial care of a client needing amputation. Also note the **strategic word**, best. Note that the correct option and option 2 address coping and defense mechanisms. This provides you with the clue that one of these options may be the correct response. In addition, knowledge of the stages of grief associated with loss will direct you to the correct option.
Rationale: An autopsy is required by state law in certain circumstances, including the sudden death of a client and a death that occurs under suspicious circumstances. A client may have provided oral or written instructions regarding an autopsy after death. If an autopsy is not required by law, these oral or written requests will be granted. If no oral or written instructions were provided, state law determines who has the authority to consent for an autopsy. Most often, the decision rests with the surviving relative or next of kin.

Test-Taking Strategy: Note the strategic words, most appropriate. Use knowledge regarding the laws and issues surrounding autopsy and therapeutic communication techniques to answer the question. Eliminate options 2 and 4 because these statements are not completely accurate and are not therapeutic in this situation. From the remaining options, the correct option is the therapeutic and appropriate response to the family.

Rationale: The mode of perinatal transmission of HIV to the fetus or neonate of an HIV-positive woman can occur during the prenatal, intrapartal, or postpartum period. HIV transmission can occur during breast-feeding. In the United States and most developed countries, HIV-positive clients are encouraged to bottle-feed their infants (the primary health care provider’s prescription is always followed). Frequent hand washing is encouraged. Support groups and community agencies can be identified to assist the parents with the newborn infant’s home care, the impact of the diagnosis of HIV infection, and available financial resources. It is recommended that infants of HIV-positive clients receive antiviral medications for the first 6 weeks of life.

Test-Taking Strategy: Note the strategic words, need for further instruction. These words indicate a negative event query and ask you to select an option that is incorrect. Recalling the methods of transmission of HIV and that breast-feeding is discouraged in the HIV-positive woman will direct you to the correct option.
Rationale: If the adolescent wears contact lenses, the adolescent should be instructed to discontinue wearing them until the infection has cleared completely. Obtaining new contact lenses would eliminate the chance of reinfection from contaminated contact lenses and would lessen the risk of a corneal ulceration.

Test-Taking Strategy: Note the strategic words, need for further information. These words indicate a negative event query and ask you to select an option that is incorrect. Options 1, 2, and 3 are comparable or alike in that they relate to avoiding the use of contact lenses during infection.

Level of Cognitive Ability: Evaluating
Client Needs: Safe and Effective Care Environment
Integrated Process: Teaching and Learning
Content Area: Pediatrics: Eye/Ear
Health Problem: Pediatric-Specific: Conjunctivitis
Priority Concepts: Client Education; Infection

897. Answer: 3

Rationale: An insulin vial in current use can be kept at room temperature for 1 month without significant loss of activity. Direct sunlight and heat must be avoided. Therefore, options 1, 2, and 4 are incorrect.

Test-Taking Strategy: Note the subject, client understanding of discharge instructions related to storage of insulin. Noting the closed-ended words “only” in option 1 and all in option 2 will assist you in eliminating these options. Recalling that direct sunlight and heat need to be avoided will assist you in eliminating option 4.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Pharmacology: Endocrine Medications: Insulin
Health Problem: Adult Health: Endocrine: Diabetes mellitus
Priority Concepts: Client Education; Glucose Regulation

898. Answer: 4

Rationale: A trans-sphenoidal hypophysectomy is a surgical approach that uses the nasal sinuses and nose for access to the pituitary gland. Based on the location of
the surgical procedure, spinal anesthesia would not be used. In addition, the hair
would not be shaved. Although ambulating is important, specific to this procedure is
avoiding brushing the teeth to prevent disruption of the surgical site.

Test-Taking Strategy: Focus on the subject, a preoperative instruction. Consider
the anatomical location and the surgical procedure itself to eliminate options 1 and 2.
Although you may be tempted to select option 3, note the location of the surgery to
direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Adult Health: Endocrine
Health Problem: Adult Health: Endocrine: Pituitary disorders
Priority Concepts: Safety; Tissue Integrity

899. Answer: 4

Rationale: Fresh fruits and vegetables provide vitamins and minerals needed for
healthy gums. Drinking water with meals has no direct effect on gums. Cracked
wheat bread may abrade the tender gums. Eating saltine crackers can also abrade the
tender gums.

Eliminate options 2 and 3 first because these measures could irritate fragile gums.
From the remaining options, eliminate option 1 by remembering that drinking water
with meals has no direct effect on gums and does not provide needed vitamins and
minerals.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Maternity: Antepartum
Health Problem: Adult Health: Hematological: Bleeding/clotting disorders
Priority Concepts: Client Education; Nutrition

900. Answer: 3

Rationale: Radiation therapy is usually delayed until a child is 8 years old,
whenever possible, to prevent retardation of bone growth and soft tissue
development. Options 1, 2, and 4 are inappropriate responses to the mother and
place the mother’s question on hold.

Test-Taking Strategy: Note the strategic word, best. Also, note the subject, effects
of radiation therapy, and the age of the child. In addition, use therapeutic
communication techniques and knowledge regarding the effects of radiation to
answer this question. Options 1, 2, and 4 are nontherapeutic and place the mother’s
inquiry on hold. Also use the child’s age as a guide in directing you to the correct
option.

Level of Cognitive Ability: Applying
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Pediatrics: Oncological  
**Health Problem:** Pediatric-Specific: Cancers  
**Priority Concepts:** Development; Safety  

901. **Answer:** 2

**Rationale:** A fresh colostomy stoma would be red and edematous, but this would decrease with time. The colostomy site then becomes pink without evidence of abnormal drainage, swelling, or skin breakdown. The nurse should document these findings, because this is a normal expectation. Options 1, 3, and 4 are inappropriate and unnecessary interventions.

**Test-Taking Strategy:** Focus on the **subject**, postoperative colostomy assessment. Note the words *returns from surgery*. The nurse should expect redness and edema at this time.

**Level of Cognitive Ability:** Applying

902. **Answer:** 3

**Rationale:** Low or oddly placed ears are associated with various congenital defects and should be reported immediately. Although the findings should be documented, the most appropriate action would be to notify the primary health care provider. Options 2 and 4 are inaccurate and inappropriate nursing actions.

**Test-Taking Strategy:** Note the **strategic words**, most appropriate. Focus on the **subject**, normal assessment findings in a newborn. Use knowledge regarding the normal assessment findings in a newborn infant to answer this question. Recalling that low-set ears are an abnormal finding will direct you to the correct option.

**Level of Cognitive Ability:** Applying

903. **Answer:** 1

**Rationale:** Jaundice, if present, is best assessed in the sclera, nail beds, and mucous membranes. Generalized jaundice appears in the skin throughout the body.
Option 4 is an inappropriate area to assess for the presence of jaundice.

**Test-Taking Strategy:** Note the **strategic word**, best. Options 2 and 3 can be eliminated first, because jaundice present in the skin is known as generalized jaundice. From the remaining options, recalling that skin discoloration can best be assessed in the nail beds will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Health Promotion and Maintenance

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Pediatrics: Gastrointestinal

**Health Problem:** Pediatric-Specific: Hepatitis

**Priority Concepts:** Clinical Judgment; Development

904. **Answer:** 2

**Rationale:** To achieve proper traction, weights need to be free-hanging, with knots kept away from the pulleys. Weights should not be kept resting on a firm surface. The head of the bed is usually kept low to provide countertraction.

**Test-Taking Strategy:** Focus on the **subject**, care for a client in traction. Attempt to visualize the traction, recalling that there must be weight to exert the pull from the traction setup. This concept will assist in eliminating options 1 and 4. Recalling that countertraction is needed will assist in eliminating option 3.

**Level of Cognitive Ability:** Creating

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Planning

**Content Area:** Adult Health: Musculoskeletal

**Health Problem:** Adult Health: Musculoskeletal: Skeletal injury

**Priority Concepts:** Mobility; Safety

905. **Answer:** 1, 2, 4

**Rationale:** When preparing the physical environment for an interview, the nurse should set the room temperature at a comfortable level. The nurse should provide sufficient lighting for the client and nurse to see each other. The nurse should avoid having the client face a strong light because the client would have to squint into the full light. Distracting objects and equipment should be removed from the interview area. The nurse should arrange seating so that the nurse and client are seated comfortably at eye level, and the nurse avoids facing the client across a desk or table, because this creates a barrier. The distance between the nurse and the client should be set by the nurse at 4 to 5 feet (1.2 to 1.5 meters). If the nurse places the client any closer, the nurse will be invading the client’s private space and may create anxiety in the client. If the nurse places the client farther away, the nurse may be seen as distant and aloof by the client.

**Test-Taking Strategy:** Focus on the **subject**, interviewing techniques. Read each intervention carefully and think about a conducive environment. Use the guidelines for preparing the physical environment for conducting an interview to select the
appropriate interventions.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Health Promotion and Maintenance  
**Integrated Process:** Nursing Process: Planning  
**Content Area:** Health Assessment/Physical Exam: Health History  
**Health Problem:** N/A  
**Priority Concepts:** Communication; Health Promotion  

906. Answer: 3

**Rationale:** An inactive older adult may become disoriented because of lack of sensory stimulation. The most appropriate nursing intervention would be to reorient the client frequently and to place objects such as a clock and a calendar in the client’s room to maintain orientation. Restraints may cause further disorientation and should not be applied unless specifically prescribed; agency policies and procedures should be followed before the application of restraints. The family can assist with orientation of the client, but it is inappropriate to ask the family to stay with the client. It is not within the scope of nursing practice to prescribe laboratory studies.

**Test-Taking Strategy:** Note the **strategic word**, best, and eliminate option 4 first because it is not within the realm of nursing practice to prescribe laboratory studies. Next, eliminate option 1 because restraints may add to the disorientation that the client is experiencing. It is inappropriate to place the responsibility of the client on the family, so eliminate option 2. Also, note the relationship between the words **disoriented** in the question and the implications of reorientation in the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Adult Health: Musculoskeletal  
**Health Problem:** Adult Health: Musculoskeletal: Skeletal injury  
**Priority Concepts:** Cognition; Sensory Perception  

907. Answer: 2

**Rationale:** Skin traction is achieved by Ace wraps, boots, or slings that apply a direct force on the client’s skin. Traction is maintained with 5 to 8 lb (2.3 to 3.6 kg) of weight, and this type of traction can cause skin breakdown. Urinary incontinence is not related to the use of skin traction. Although constipation can occur as a result of immobility and monitoring bowel sounds may be a component of the assessment, this intervention is not the priority assessment. There are no pin sites with skin traction.

**Test-Taking Strategy:** Note the **strategic word**, priority. Eliminate option 4 first because there are no pin sites with skin traction. Visualizing the traction setup and knowledge of the complications associated with this type of traction will direct you to the correct option.

**Level of Cognitive Ability:** Creating
**Client Needs**: Physiological Integrity  
**Integrated Process**: Nursing Process—Assessment  
**Content Area**: Adult Health: Musculoskeletal  
**Health Problem**: Adult Health: Musculoskeletal: Skeletal injury  
**Priority Concepts**: Mobility; Tissue Integrity  
**Reference**: Lewis et al. (2017), pp. 1470-1471.

908. **Answer**: 1

**Rationale**: A psychosocial assessment of a client who is immobilized would most appropriately include the need for sensory stimulation. This assessment should also include such factors as body image, past and present coping skills, and coping methods used during the period of immobilization. Although home care support, the ability to perform activities of daily living, and transportation are components of an assessment, they are not as specifically related to psychosocial adjustment as is the need for sensory stimulation.

**Test-Taking Strategy**: Focus on the strategic words, most appropriate, and note the subject, psychosocial adjustment. Option 3 can be eliminated first because it relates to physiological integrity rather than psychosocial integrity. Next, eliminate options 2 and 4 because they are most closely related to physical supports, rather than psychosocial needs of the client.

**Level of Cognitive Ability**: Applying  
**Client Needs**: Psychosocial Integrity  
**Integrated Process**: Nursing Process—Assessment  
**Content Area**: Adult Health: Musculoskeletal  
**Health Problem**: Adult Health: Musculoskeletal: Skeletal Injury  
**Priority Concepts**: Mobility; Sensory Perception  

909. **Answer**: 3

**Rationale**: Complex scientific or medical terminology should be avoided when counseling an Amish client (or any client). When counseling a female Amish client, most often the husband and wife will want to discuss health care options together. Standing close and speaking loudly is inappropriate in most counseling situations.

**Test-Taking Strategy**: Use knowledge of the Amish society and therapeutic communication techniques to answer this question. Options 2 and 4 can be eliminated first because option 4 is inappropriate and option 2 is not a therapeutic intervention. In addition, note that options 2 and 3 are opposite, which may indicate that one of these options is correct. Option 1 can be eliminated because of Amish cultural habits.

**Level of Cognitive Ability**: Applying  
**Client Needs**: Psychosocial Integrity  
**Integrated Process**: Culture and Spirituality  
**Content Area**: Foundations of Care: Spirituality, Culture, and Ethnicity  
**Health Problem**: N/A  
**Priority Concepts**: Communication; Culture  

2603

910. **Answer:** 1

**Rationale:** Assault occurs when a person puts another person in fear of harmful or offensive contact and the victim fears and believes that harm will result from the threat. In this situation, the nurse could be accused of the tort of assault. Battery is the intentional touching of another’s body without the person’s consent. Slander is verbal communication that is false and harms the reputation of another. Invasion of privacy is committed when the nurse intrudes into the client’s personal affairs or violates confidentiality.

**Test-Taking Strategy:** Note the subject, legal implications for nursing care. Focusing on the words used by the nurse and noting that the nurse threatens the client will direct you to the correct option.

**Level of Cognitive Ability:** Applying

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Leadership/Management: Ethical/Legal

**Health Problem:** N/A

**Priority Concepts:** Ethics; Health Care Law

911. **Answer:** 4

**Rationale:** When creating nursing assignments, the nurse needs to consider the skills and educational level of the nursing staff. Frequent temperature checks and ambulation can most appropriately be provided by the AP, considering the clients identified in each option. The client on the mechanical ventilator requiring frequent assessment and suctioning should most appropriately be cared for by the RN. The LPN is skilled in urinary catheterization, so the client in option 4 would be assigned to this staff member.

**Test-Taking Strategy:** Note the strategic word, best; focus on the subject, the principles related to delegation and assignments; and consider the education and job position as described by the Nurse Practice Act and employee guidelines. Note the word assessment in option 3. This should alert you that this client should be assigned to the RN. Options 1 and 2 can be eliminated because an AP can perform these tasks.

**Level of Cognitive Ability:** Creating

**Client Needs:** Safe and Effective Care Environment

**Integrated Process:** Nursing Process—Planning

**Content Area:** Leadership/Management: Delegating/Supervising

**Health Problem:** N/A

**Priority Concepts:** Care Coordination; Safety

Reference: Lewis et al. (2017), pp. 11-12.

912. **Answer:** 1

**Rationale:** The jaw thrust without the head tilt maneuver is used when head or
neck trauma is suspected. This maneuver opens the airway while maintaining proper head and neck alignment, reducing the risk of further damage to the neck. Options 2, 3, and 4 are incorrect. In addition, it is unlikely that the nurse would be able to obtain data about the client’s history.

Test-Taking Strategy: Focus on the figure and note that it is a jaw thrust maneuver. Eliminate option 2 because of the closed-ended word “all.” Noting that the client requires CPR and that the figure illustrates that the client’s neck remains stable will assist in eliminating options 3 and 4.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Complex Care: Basic Life Support/Cardiopulmonary Resuscitation/Cardiac Arrest
Health Problem: N/A
Priority Concepts: Gas Exchange; Safety

913. Answer: 4

Rationale: The client needs to be instructed to avoid exposure to the sun. Because of the risk of altered skin integrity, options 1, 2, and 3 are accurate measures in the care of a client receiving external radiation therapy.

Test-Taking Strategy: Note the strategic words, need for further instruction. These words indicate a negative event query and ask you to select an option that is an incorrect statement. Eliminate option 1 because of the word gently and option 2 because of the word loose. From the remaining options, recalling that sun exposure is to be avoided will assist in answering the question.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Adult Health: Oncology
Health Problem: N/A
Priority Concepts: Client Education; Tissue Integrity

914. Answer: 1.5

Rationale: It is necessary to convert 150 mcg to mg. In the metric system, to convert smaller to larger, divide by 1000 or move the decimal 3 places to the left: 150 mcg = 0.15 mg. Next, use the formula to calculate the correct dose.

Formula:

\[
\frac{\text{Desired}}{\text{Available}} \times \text{Quantity} = \text{tablet (s)}
\]
Test-Taking Strategy: Focus on the subject, a medication calculation problem. In this medication calculation problem, it is necessary first to convert micrograms to milligrams. Next, use the formula to calculate the correct dose. Recheck your work using a calculator, and make sure that the answer makes sense.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Skills: Dosage Calculations

**Health Problem:** Adult Health: Endocrine: Thyroid Disorders

**Priority Concepts:** Clinical Judgment; Safety

915. **Answer:** 4

**Rationale:** The most common side effect of metformin is gastrointestinal disturbances, including decreased appetite, nausea, and diarrhea. These generally subside over time. This medication does not cause weight gain; clients lose an average of 7 to 8 lb (3.2 to 3.6 kg) because the medication causes nausea and decreased appetite. Although hypoglycemia can occur, it is not the most common side effect. Flushing and palpitations are not specifically associated with this medication.

**Test-Taking Strategy:** Note the strategic word, most. To answer correctly, it is necessary to recall that the most common side effect of metformin is gastrointestinal disturbances.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Teaching and Learning

**Content Area:** Pharmacology: Endocrine Medications: Oral hypoglycemics

**Health Problem:** Adult Health: Endocrine: Diabetes mellitus

**Priority Concepts:** Client Education; Glucose Regulation

916. **Answer:** 1, 3, 5, 6

**Rationale:** During a seizure, the nurse should stay with the child to reduce the risk of injury and allow for observation and timing of the seizure. The child is not restrained, because this could cause injury to the child. The child is placed on his or her side in a lateral position. Nothing is placed in the child’s mouth during a seizure because this could injure the child’s mouth, gums, or teeth. Positioning on the side prevents aspiration, because saliva drains out of the corner of the child’s mouth. The nurse should loosen clothing around the child’s neck and ensure a patent airway.

**Test-Taking Strategy:** Focus on the subject, care of the child experiencing...
seizures, and visualize this clinical situation. Recalling that airway patency and safety are the priorities will assist in determining the correct interventions. 

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Pediatrics: Neurological  
**Health Problem:** Pediatric-Specific: Seizures  
**Priority Concepts:** Intracranial Regulation; Safety  
**Reference:** McKinney et al. (2018), pp. 1299, 1301.

917. **Answer:** 1, 2, 3

**Rationale:** Nocturia, incontinence, and an enlarged prostate are characteristics of BPH and need to be assessed for in all male clients over 50 years of age. Nocturnal emissions are commonly associated with prepubescent males. Low testosterone levels (not BPH) may be associated with a decreased desire for sexual intercourse.

**Test-Taking Strategy:** Focus on the **subject**, characteristics of BPH. Thinking about the pathophysiology associated with this disorder will assist you in answering correctly.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Renal and Urinary  
**Health Problem:** Adult Health: Renal and Urinary: Obstructive problems  
**Priority Concepts:** Clinical Judgment; Elimination  
**Reference:** Lewis et al. (2017), p. 1269.

918. **Answer:** 1

**Rationale:** Setting priorities means deciding which client needs or problems require immediate action and which can be delayed until a later time because they are not urgent. Client problems that involve actual or life-threatening concerns are always considered first. Although completing care in a reasonable time frame, time constraints, and obtaining needed supplies are components of time management, these items are not the priority in planning care for the client, based on the options provided.

**Test-Taking Strategy:** Note the **strategic word**, **priority**. Recall the principles related to prioritizing to answer the question. Noting the words **life-threatening** in the correct option will assist in directing you to this option.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Safe and Effective Care Environment  
**Integrated Process:** Teaching and Learning  
**Content Area:** Leadership/Management: Prioritizing  
**Health Problem:** N/A  
**Priority Concepts:** Care Coordination; Clinical Judgment  
Rationale: Laboratory determinations of the serum thyroid-stimulating hormone (TSH) level are an important means of evaluation. Successful therapy causes elevated TSH levels to decline. These levels begin their decline within hours of the onset of therapy and continue to decrease as plasma levels of thyroid hormone build up. If an adequate dosage is administered, TSH levels remain suppressed for the duration of therapy. Although energy levels may increase and the client’s mood may improve following effective treatment, these are not noted until normal thyroid hormone levels are achieved with medication therapy. An increase in the blood glucose level is not associated with this condition.

Test-Taking Strategy: Focus on the subject, therapeutic effects of this medication. Note the words expected outcome. Relate the diagnosis of hypothyroidism with thyroid hormone levels in the correct option.

Level of Cognitive Ability: Evaluation
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Evaluation
Content Area: Pharmacology: Endocrine Medications: Thyroid hormones
Health Problem: Adult Health: Endocrine: Thyroid disorders
Priority Concepts: Cellular Regulation; Evidence

Rationale: Risk factors for breast cancer include nulliparity or first child born after age 30 years; early menarche; late menopause; family history of breast cancer; high-dose radiation exposure to the chest; and previous cancer of the breast, uterus, or ovaries. In addition, specific inherited mutations in BReast CAncer (BRCA)1 and BRCA2 increase the risk of female breast cancer; these mutations are also associated with an increased risk for ovarian cancer.

Test-Taking Strategy: Focus on the subject, the risk factors associated with breast cancer. Thinking about the physiology associated with the reproductive system and the most common causes of cancer will assist in answering the question.

Level of Cognitive Ability: Analyzing
Client Needs: Health Promotion and Maintenance
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Oncology
Health Problem: Adult Health: Cancer: Breast
Priority Concepts: Cellular Regulation; Client Education

Rationale: An inflammatory reaction such as acute pancreatitis can cause paralytic ileus, the most common form of nonmechanical obstruction. Inability to pass flatus is a clinical manifestation of paralytic ileus. Loss of sphincter control is not a sign of paralytic ileus. Pain is associated with paralytic ileus, but the pain usually manifests
as a more constant generalized discomfort. Option 4 is the description of the physical finding of liver enlargement. The liver may be enlarged in cases of cirrhosis or hepatitis. Although this client may have an enlarged liver, an enlarged liver is not a sign of paralytic ileus or intestinal obstruction.

**Test-Taking Strategy:** Focus on the **subject**, clinical manifestations of paralytic ileus. Noting the word *paralytic* will assist in directing you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Gastrointestinal  
**Health Problem:** Adult Health: Gastrointestinal: GI Accessory organs  
**Priority Concepts:** Elimination; Inflammation  
**Reference:** Lewis et al. (2017), pp. 950-951.

922. **Answer:** 1

**Rationale:** For the first 12 hours after gastric surgery, the nasogastric tube drainage may be dark brown to dark red. Later, the drainage should change to a light yellowish-brown color. The presence of bile may cause a green tinge. The PHCP should be notified if dark red drainage, a sign of hemorrhage, is noted 24 hours postoperatively.

**Test-Taking Strategy:** Focus on the **subject**, the need to notify the PHCP. Recall that bleeding is a concern in the postoperative client. This concept will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Analysis  
**Content Area:** Adult Health: Gastrointestinal  
**Health Problem:** Adult Health: Gastrointestinal: Upper GI Disorders  
**Priority Concepts:** Clinical Judgment; Collaboration  
**Reference:** Lewis et al. (2017), p. 344.

923. **Answer:** 1

**Rationale:** The client should take a deep breath, because the client’s airway will be temporarily obstructed during tube removal. The client is then told to hold the breath and the tube is withdrawn slowly and evenly over the course of 3 to 6 seconds (coil the tube around the hand while removing it) while the breath is held. Bearing down could inhibit the removal of the tube. Exhaling is not possible during removal because the airway is temporarily obstructed during removal. Breathing normally could result in aspiration of gastric secretions during inhalation.

**Test-Taking Strategy:** Focus on the **subject**, the procedure for removal of a nasogastric tube, and attempt to visualize the process of tube removal to direct you to the correct option. Remember, holding the breath facilitates the process of removal.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Skills: Tube Care
Health Problem: N/A
Priority Concepts: Gas Exchange; Safety

924. Answer: 3

Rationale: When a client is experiencing respiratory acidosis, the respiratory rate and depth increase in an attempt to compensate. The client also experiences headache; restlessness; mental status changes, such as drowsiness and confusion; visual disturbances; diaphoresis; cyanosis as the hypoxia becomes more acute; hyperkalemia; rapid, irregular pulse; and dysrhythmias. Options 1, 2, and 4 are not specifically associated with this disorder.

Test-Taking Strategy: Focus on the subject, clinical manifestations associated with respiratory acidosis, and use knowledge of the signs and symptoms of respiratory acidosis to answer this question. Eliminate options 2 and 4 first because they are comparable or alike and address a decreased respiratory rate. Remember that headache, restlessness, and confusion occur in respiratory acidosis.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Foundations of Care: Acid–Base
Health Problem: Adult Health: Respiratory: Obstructive Pulmonary Disease
Priority Concepts: Acid–Base Balance; Clinical Judgment

925. Answer: 4

Rationale: Distention, vomiting, and abdominal pain are a few of the symptoms associated with intestinal obstruction. Nasogastric tubes may be used to remove gas and fluid from the stomach, relieving distention and vomiting. Bowel sounds return to normal as the obstruction is resolved and normal bowel function is restored. Discontinuing the nasogastric tube before normal bowel function may result in a return of the symptoms, necessitating reinsertion of the nasogastric tube. Serum electrolyte levels, pH of the gastric aspirate, and tube placement are important assessments for the client with a nasogastric tube in place but would not assist in determining the readiness for removing the nasogastric tube.

Test-Taking Strategy: Eliminate options 2 and 3 first because they are comparable or alike. Assessing the pH of the gastric aspirate is one method of assessing tube placement. Also, note the strategic word, priority. Focus on the client’s diagnosis to direct you to the correct option.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: Lower GI disorders
Priority Concepts: Clinical Judgment; Safety

926. Answer: 1

Rationale: The enema is never administered while on a toilet due to safety. The enema is administered while the client is in a left side-lying (Sims’) position with the right knee flexed. This allows enema solution to flow downward by gravity along the natural curve of the sigmoid colon and rectum. It is important for the client to retain the fluid for as long as possible to promote peristalsis and defecation. If the client complains of fullness or pain, the flow is stopped for 30 seconds and restarted at a slower rate. The higher the solution container is held above the rectum, the faster the flow and the greater the force in the rectum; this could increase cramping.

Test-Taking Strategy: Note the strategic words, need for further instruction. This indicates a negative event query, and the need to select the option that is incorrect. Eliminate options 3 and 4 first because they are comparable or alike. From the remaining options, focusing on the subject, safety, will direct you to the correct option.

Level of Cognitive Ability: Evaluating
Client Needs: Physiological Integrity
Integrated Process: Teaching and Learning
Content Area: Skills: Elimination
Health Problem: N/A
Priority Concepts: Client Education; Elimination

927. Answer: 4

Rationale: Negative reinforcement when the stimulus is produced is descriptive of aversion therapy. Options 1, 2, and 3 are characteristics of self-control therapy.

Test-Taking Strategy: Note the strategic words, need for further teaching. These words indicate a negative event query and ask you to select an option that is incorrect. Think about the subject, self-control. This subject will assist you in answering correctly.

Level of Cognitive Ability: Evaluating
Client Needs: Psychosocial Integrity
Integrated Process: Teaching and Learning
Content Area: Mental Health
Health Problem: Mental Health: Coping
Priority Concepts: Anxiety; Stress

928. Answer: 2, 4, 5, 6

Rationale: The nurse should teach the client how to care for the stoma, depending on the type of laryngectomy performed. Most interventions focus on protection of the stoma and the prevention of infection. Interventions include obtaining a
MediAlert bracelet, preventing debris from entering the stoma, avoiding exposure to people with infections, and avoiding swimming and using care when showering. Additional interventions include wearing a stoma guard or high-collared clothing to protect the stoma, increasing the humidity in the home, and increasing fluid intake to 3000 mL/day to keep the secretions thin.

**Test-Taking Strategy:** Focus on the **subject**, client instructions regarding stoma care. Recalling that most interventions focus on protection of the stoma and the prevention of infection will assist in identifying the client instructions for home care.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Oncology  
**Health Problem:** Adult Health: Cancer: Laryngeal and lung  
**Priority Concepts:** Client Education; Gas Exchange  
**Reference:** Lewis et al. (2017), p. 495.

929. **Answer:** 21

**Rationale:** Use the intravenous flow rate formula.  
**Formula:**

\[
\frac{\text{Total volume prescribed}}{\text{Time in minutes}} \times \frac{\text{Drop factor}}{\text{Volume}} = \text{gtt/minute}
\]

\[
\frac{2000 \text{ mL} \times 15 \text{ gtt/mL}}{1440 \text{ minutes}} = 20.8 \text{ gtt/minute} = 21 \text{ gtt/minute}
\]

**Test-Taking Strategy:** Focus on the **subject**, a medication calculation. Use the formula for calculating intravenous flow rates when answering the question. Verify the answer using a calculator, and be sure to round the answer to the nearest whole number.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Skills: Dosage Calculations  
**Health Problems:** N/A  
**Priority Concepts:** Clinical Judgment; Safety  
**Reference:** Potter et al. (2017), pp. 978-979.

930. **Answer:** 2
Rationale: In the first few hours after surgery, the drainage from the chest tube is bloody. After several hours, it becomes serosanguineous. The client should not experience frequent clotting. Proper chest tube function should allow for drainage of blood before it has the chance to clot in the chest or the tubing.

Test-Taking Strategy: Focus on the subject, expected findings after thoracic surgery. Recall that after thoracic surgery, there may be considerable capillary oozing for hours in the postoperative period. This will lead you to choose the bloody drainage option over the serous or serosanguineous drainage options. Knowing that patent chest tubes do not allow blood to collect in the pleural space eliminates the option of blood with clots.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Respiratory
Health Problem: N/A
Priority Concepts: Clinical Judgment; Gas Exchange

931. Answer: 1, 2, 3, 5

Rationale: If the client begins to hemorrhage from the surgical site after radical neck dissection, the nurse elevates the head of the bed to maintain airway patency and prevent aspiration. The nurse applies pressure over the bleeding site and calls the surgeon immediately. The nurse also monitors the client’s airway and vital signs.

Test-Taking Strategy: Focus on the subject, nursing actions for hemorrhage, and on the client situation. Use the ABCs—airway, breathing, and circulation—to assist you in answering the question. Note that lowering the head of the bed to a flat position increases the client’s risk for aspiration.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Complex Care: Emergency Situations/Management
Health Problem: Adult Health: Cancer: Laryngeal and lung
Priority Concepts: Clinical Judgment; Gas Exchange

932. Answer: 2

Rationale: To prevent transmission of hepatitis, vaccination of the partner is advised. In addition, a condom is advised during sexual intercourse. Alcohol should be avoided because it is detoxified in the liver and may interfere with recovery. Rest is especially important until laboratory studies show that liver function has returned to normal. The client’s activity is increased gradually, and the client should not return to work right away.

Test-Taking Strategy: Focus on the strategic words, need for further teaching. These words indicate a negative event query and ask you to select an option that is incorrect. Think about the pathophysiology associated with hepatitis to direct you to
the incorrect client statement. Remember that rest is needed for the liver to heal.

**Level of Cognitive Ability:** Evaluating  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Teaching and Learning  
**Content Area:** Adult Health: Gastrointestinal  
**Health Problem:** Adult Health: Gastrointestinal: GI Accessory organs  
**Priority Concepts:** Client Education; Infection  

933. **Answer:** 3, 4, 6

**Rationale:** The clinical manifestations of hypothyroidism are the result of decreased metabolism from low levels of thyroid hormone. Interventions are aimed at replacement of the hormone and providing measures to support the signs and symptoms related to decreased metabolism. The client often has cold intolerance and requires a warm environment. The nurse encourages the client to consume a well-balanced diet that is low in fat for weight reduction and high in fluids and high-fiber foods to prevent constipation. Iodine preparations may be used to treat hyperthyroidism. Iodine preparations decrease blood flow through the thyroid gland and reduce the production and release of thyroid hormone; they are not used to treat hypothyroidism. The client is instructed to notify the PHCP if chest pain occurs because it could be an indication of overreplacement of thyroid hormone.

**Test-Taking Strategy:** Focus on the subject, hypothyroidism. Recalling the manifestations of this disorder and that in this disorder the client has a decreased metabolic rate will assist in determining the appropriate interventions.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Adult Health: Endocrine  
**Health Problem:** Adult Health: Endocrine: Thyroid disorders  
**Priority Concepts:** Caregiving; Thermoregulation  
**Reference:** Lewis et al. (2017), pp. 1168-1169.

934. **Answer:** 1

**Rationale:** Plugging a tracheostomy tube is usually done by inserting the tracheostomy plug (decannulation stopper) into the opening of the outer cannula. This closes off the tracheostomy, and airflow and respiration occur normally through the nose and mouth. When plugging a cuffed tracheostomy tube, the cuff must be deflated. If it remains inflated, ventilation cannot occur, and respiratory arrest could result. A tracheostomy plug could not be placed in a tracheostomy if an inner cannula was in place. The ability to swallow or speak is unrelated to weaning and plugging the tube.

**Test-Taking Strategy:** Focus on the subject, care of the client with a tracheostomy, and note the word required in the question. Think about the structure and function of a tracheostomy tube. Recalling that an inflated cuff would cause airway obstruction will assist in directing you to the option that addresses a priority physiological need.
**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Skills: Tube care  
**Health Problem:** N/A  
**Priority Concepts:** Gas Exchange; Safety  
**Reference:** Lewis et al. (2017), pp. 487-488.

935. **Answer:** 1

**Rationale:** Hypertension, cardiovascular disease, diabetes mellitus, and obesity are associated with the development of glaucoma. Options 2, 3, and 4 do not identify risk factors associated with this eye disorder.  
**Test-Taking Strategy:** Focus on the subject, a risk factor associated with glaucoma. Recall that glaucoma is associated with increased pressure in the eye. This will assist to direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Assessment  
**Content Area:** Adult Health: Eye  
**Health Problem:** Adult Health: Eye: Glaucoma  
**Priority Concepts:** Health Promotion; Sensory Perception  

936. **Answer:** 4

**Rationale:** The nurse places an eye patch over the client’s affected eye to reduce eye movement. Some clients may need bilateral patching. Depending on the location and size of the retinal break, activity restrictions may be needed immediately. These restrictions are necessary to prevent further tearing or detachment and to promote drainage of any subretinal fluid. Therefore, reading and watching television are not allowed. The client’s position is prescribed by the primary health care provider; normally, the prescription is to lie flat.  
**Test-Taking Strategy:** Focus on the subject, retinal detachment. Remember that the eye needs to be protected and rested. This should direct you to the correct option.

**Level of Cognitive Ability:** Analyzing  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Adult Health: Eye  
**Health Problem:** Adult Health: Eye: Retinal detachment  
**Priority Concepts:** Sensory Perception; Safety  

937. **Answer:** 3

**Rationale:** Clients at greatest risk for deep vein thrombosis and pulmonary emboli
are immobilized clients. Basic preventive measures include early ambulation, leg elevation, active leg exercises, elastic stockings, and intermittent pneumatic calf compression. Keeping the client well hydrated is essential because dehydration predisposes to clotting. A pillow under the knees may cause venous stasis. Heat should not be applied without a primary health care provider’s prescription.

Test-Taking Strategy: Note the strategic word, most. Focus on the subject, measures to prevent deep vein thrombosis and pulmonary emboli. Use basic principles related to the care of the immobile client to answer this question.

Level of Cognitive Ability: Creating
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Planning
Content Area: Adult Health: Cardiovascular
Health Problem: Adult Health: Cardiovascular: Vascular disorders
Priority Concepts: Clinical Judgment; Clotting

938. Answer: 1

Rationale: A crisis is an acute, time-limited state of disequilibrium resulting from situational, developmental, or societal sources of stress. A person in this state is temporarily unable to cope with or adapt to the stressor by using previous coping mechanisms. The person who intervenes in this situation (the nurse) “takes over” for the client (authority) who is not in control and devises a plan (action) to secure and maintain the client’s safety. When this has occurred, the nurse works collaboratively with the client (participates) in developing new coping and problem-solving strategies.

Test-Taking Strategy: Note the strategic word, priority. A client who experiences a suicidal crisis is in a state of acute disequilibrium. Remember that in a crisis an authority figure must emerge to take action.

Level of Cognitive Ability: Applying
Client Needs: Psychosocial Integrity
Integrated Process: Nursing Process—Implementation
Content Area: Mental Health
Health Problem: Mental Health: Suicide
Priority Concepts: Mood and Affect; Safety

939. Answer: 2

Rationale: The client with tuberculosis must have sputum cultures performed every 2 to 4 weeks after initiation of antituberculosis medication therapy. The client may return to work when the results of three sputum cultures are negative, because the client is considered noninfectious at that point. Options 1, 3, and 4 are not reliable determinants of a noninfectious status.

Test-Taking Strategy: Focus on the subject, concepts related to tuberculosis. Knowing that a positive tuberculin skin test never reverts to negative helps you eliminate option 4. From the remaining options, think about the mode of
transmission of tuberculosis to direct you to the correct option. Remember, three negative sputum cultures are required.

Level of Cognitive Ability: Applying
Client Needs: Safe and Effective Care Environment
Integrated Process: Teaching and Learning
Content Area: Foundations of Care: Infection Control
Health Problem: Adult Health: Respiratory: Tuberculosis
Priority Concepts: Infection; Safety

940. Answer: 3

Rationale: This client is in a severe state of anxiety. When a client is in a severe or panic state of anxiety, it is crucial for the nurse to remain with the client. The client in a severe state of anxiety would be unable to learn relaxation techniques. Discussing the assault at this point would increase the client’s level of anxiety further. Placing the client in a quiet room alone may also increase the anxiety level.

Test-Taking Strategy: Note the strategic word, priority. The priority action in this situation is to remain with the client.

Level of Cognitive Ability: Applying
Client Needs: Safe and Effective Care Environment
Integrated Process: Nursing Process—Implementation
Content Area: Mental Health
Health Problem: Mental Health: Anxiety disorder
Priority Concepts: Anxiety; Caregiving

941. Answer: 2

Rationale: Laboratory findings do not establish the diagnosis of appendicitis, but there is often an elevation of the white blood cell count (leukocytosis) with a shift to the left (an increased number of immature white blood cells). Options 1, 3, and 4 are incorrect because they are not associated findings in acute appendicitis.

Test-Taking Strategy: Focus on the subject, appendicitis. Knowledge that an inflammatory process causes an increase in the white blood cell count will assist you in eliminating options 1 and 3. From the remaining options, it is necessary to understand the significance of a shift to the left.

Level of Cognitive Ability: Analyzing
Client Needs: Physiological Integrity
Integrated Process: Nursing Process—Assessment
Content Area: Adult Health: Gastrointestinal
Health Problem: Adult Health: Gastrointestinal: GI Accessory organs
Priority Concepts: Cellular Regulation; Inflammation

942. Answer: 3
**Rationale:** Lack of ability to cope effectively may be evidenced by a client’s inability to meet basic needs, inability to meet role expectations, alteration in social participation, use of inappropriate defense mechanisms, or impairment of usual patterns of communication. Anxiety is a broad description and can occur as a result of many triggers; although the client was experiencing anxiety, the client’s concern now is the ability to meet role expectations and financial obligations. There is no information in the question that indicates an unrealistic outlook or disturbances in thoughts and ideas.

**Test-Taking Strategy:** Note the **strategic word**, priority. Focus on the **subject**, concerns regarding the ability to meet role expectations and financial obligations. Option 1 can be eliminated because the client was previously experiencing anxiety. Eliminate options 2 and 4 because there are no data in the question that address these problems.

**Level of Cognitive Ability:** Creating  
**Client Needs:** Psychosocial Integrity  
**Integrated Process:** Nursing Process—Planning  
**Content Area:** Mental Health  
**Health Problem:** Mental Health: Anxiety disorders  
**Priority Concepts:** Anxiety; Coping  
**Reference:** Varcarolis (2017), pp. 142-143.

943. **Answer:** 2

**Rationale:** Bubbling in the water seal chamber is caused by air passing out of the pleural space into the fluid in the chamber. Intermittent (not constant) bubbling is normal. It indicates that the system is accomplishing one of its purposes, removing air from the pleural space. Continuous bubbling during inspiration and expiration indicates that an air leak exists. If this occurs, it must be corrected. Notifying the primary health care provider and changing the chest tube drainage system are not indicated at this time.

**Test-Taking Strategy:** Note the **strategic words**, most appropriate. Note the **subject**, chest tube drainage systems, and focus on the words **intermittent bubbling** and **water seal chamber**. Recalling that intermittent (not constant) bubbling is normal in this chamber will direct you to the correct option.

**Level of Cognitive Ability:** Applying  
**Client Needs:** Physiological Integrity  
**Integrated Process:** Nursing Process—Implementation  
**Content Area:** Skills: Tube care  
**Health Problem:** N/A  
**Priority Concepts:** Clinical Judgment; Gas Exchange  
**Reference:** Lewis et al. (2017), p. 525.

944. **Answer:** 1

**Rationale:** Although frequency and intensity of bowel sounds vary depending on the phase of digestion, normal bowel sounds are relatively high-pitched clicks or gurgles. Loud gurgles (borborygmi) indicate hyperperistalsis and are commonly
associated with nausea and vomiting. A swishing or buzzing sound represents turbulent blood flow associated with a bruit. Bruits are not normal sounds. Bowel sounds are very high-pitched and loud (hyper-resonance) when the intestines are under tension, such as in intestinal obstruction. Therefore, options 2, 3, and 4 are incorrect.

**Test-Taking Strategy:** Note the **subject**, techniques for abdominal assessment. Normally, bowel sounds are audible in all four quadrants, so options 2 and 4 can be eliminated. From the remaining options, focus on the **data in the question** and note that the client has nausea and vomiting; this will direct you to the correct option.

**Level of Cognitive Ability:** Analyzing

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Assessment

**Content Area:** Health Assessment/Physical Exam: Abdomen

**Health Problem:** Adult Health: Gastrointestinal: Upper GI disorders

**Priority Concepts:** Elimination; Health Promotion

945. **Answer:** 20

**Rationale:** Use the medication calculation formula.

**Formula:**

\[
\frac{\text{Prescribed}}{\text{Available}} \times \text{Quantity} = \text{mL/dose}
\]

\[
\frac{800 \text{ mg}}{200 \text{ mg}} \times 5 \text{ mL} = 20 \text{ mL}
\]

**Test-Taking Strategy:** Note the **subject**, medication calculations. Review the label for the correct reconstitution, which states 200 mg in 5 mL. Calculate the prescribed number of milligrams per milliliter. Use a calculator to verify the answer and make sure that the answer makes sense.

**Level of Cognitive Ability:** Applying

**Client Needs:** Physiological Integrity

**Integrated Process:** Nursing Process—Implementation

**Content Area:** Skills: Dosage Calculations

**Health Problem:** N/A

**Priority Concepts:** Clinical Judgment; Safety

**Reference:** Potter et al. (2017), pp. 978-979.

Transposition of great arteries/vessels 452
Transurethral resection of bladder tumor 552
Transurethral resection of the prostate (TURP) 550
Transvenous pacing, invasive 710
Transverse fracture 872b
Transverse lie, in labor and birth 304, 305
Trapeze bar, for proper positioning 213
Trauma
  birth 341
  of bladder 782
  in ear disorders 812–813
  spinal cord 1050–1051
Traumatic head injury 837–839, 1047, 1048
  description of 837
  types of 837
Treadmill testing 700
Trendelenburg test 723
Trendelenburg’s position 211
  reverse 210
Trendelenburg’s sign 478, 479
Treponema pallidum 293
Tretinoin 525
Triage 85–86, 85–86
Trichomoniasis, in pregnancy 272, 273, 294
Tricuspid atresia 451
Tricuspid valve 696
  disorders of 719
Tricyclic antidepressants 979–980, 979
Trigeminal nerve 163–164
Trigeminal neuralgia 845–846
Triiodothyronine
  diagnostic testing of 580
  hypersecretion of 587
Trimethoprim-sulfamethoxazole (TMP-SMZ) 789, 789
Triple lumen urinary catheter 1016
Triple therapy, for Helicobacter pylori infection 651, 651
Tripod positioning 431
Trochanter rolls, for proper positioning 213
Trochlear nerve 163–164
Troponin 698
   in angina 713
   in myocardial infarction 714
Trousseau’s sign 103f, 588
True labor 306, 306b
True pelvis 258
Truncus arteriosus 452
TSE See Testicular self-examination (TSE)
TST See Tuberculin skin test (TST)
Tubal ectopic pregnancy 284, 285f
Tube(s) 1013b

   Salem sump 1011–1012, 1012f
   tracheostomy 1018–1021, 1019b, 1019f, 1020–1021t
   urinary and renal 1016
Tube dislodgment, of tracheostomy 1020–1021t
Tube feedings
   gastrointestinal 1012–1014
   positioning clients for 211
Tube obstruction, of tracheostomy 1020–1021t
Tuberculin skin test (TST) 442, 442b, 672, 672t
in pregnancy 273
Tuberculin syringe 186, 186f
Tuberculosis 671–673, 671b, 672t, 673b
  in children 442–443
  medications for 683, 683b
  in pregnancy 295
Tubing
  for blood products administration 1009b
  intravenous 994–995, 994–995f
    flow rates and 188
Tubules 756
Tularemia 177–178
Tumor(s)
  brain, pediatric 392–393
  grading and staging of 531
  intestinal 545–547
  neuroblastoma 391
  solid 531
  Wilms’ 390–391
Tumor lysis syndrome 556, 1032
Tumor marker, in ovarian cancer 541
Tuning fork tests, for hearing assessment 155
Tunneled central venous catheters 1000–1001, 1002f
Turner’s sign 637
TURP See Transurethral resection of the prostate (TURP)
Tympanic cavity 807
Tympanic measurement, of temperature 121
Tympanic membrane
  assessment of 156
  injury to 813
Type 1 diabetes mellitus 589
Type 2 diabetes mellitus 589
  medications for 610–612, 611t
Tyramine 981, 981b, 981f

ocular 801
in pregnancy 274
quantitative, for bone mineral density measurement 871
Umbilical blood sampling, percutaneous 274
Umbilical cord
assessment of, in newborn 343
in fetal circulation 261, 262f
prolapsed, in labor and birth 318, 319f
Umbilical hernia 415
Umbrella option 34, 35b
Uncircumcised newborn 348
Unconscious client 835, 836b
Undoing defense mechanisms 923b
Unfreezing, in change process 78, 78f
Uniform Anatomical Gift Act 62
Unilateral neglect 843
Uninsured and underinsured individuals, care for 48
Unit, in drug measurement 183
Unit dosage per hour, infusion prescribed by 188, 188b
100-unit insulin syringe 186, 187f
Unplanned change 78
Unstable angina 713
Upper gastrointestinal endoscopy 624
Upper gastrointestinal tract study 623
Upper respiratory airway 658
Urea breath test 626
Urea nitrogen 758
Uremic syndrome 766
Ureteral tube 1015f, 1016
Ureteritis 776
Ureterolithotomy 779
Ureterostomy 553–554
Urethral orifice, epispadias and hypospadias of 462
Urethritis 775
Urinalysis 758, 758t
   in pregnancy 274
Urinary catheters 1016, 1017b
Urinary diversion, for bladder cancer 552, 553f
Urinary elimination, in dying client 241b
Urinary retention, postoperative 201
Urinary tract
   antiseptics 788, 789b
   bladder, as radiation therapy side effect 390t
   chronic kidney disease manifestations in 763b
   physiological maternal changes of, in postpartum period 325
Urinary tract infection 209, 774–775, 774–775b
   in pregnancy 295–296
Urinary urgency and frequency, in pregnancy 270
Urine
   culture and sensitivity testing 759
   24-hour collection of 758
   production of 756
Urine culture, in pregnancy 274
Urine output
   in acute kidney injury 761
   in cardiogenic shock 1043
   postoperative 199
in preeclampsia 289t
Urine specific gravity 758–759
  in dehydration, pediatric 398t
Urine testing, in diabetes mellitus 591
  pediatric 401
Urography, intravenous 759–760
Urolithiasis 777
Urosepsis 1047
Uterine activity, suppressing, tocolytics in 361, 362t
Uterine atony, postpartum 333, 334f
Uterine contractions, in labor and birth 304
Uterus 258
  cancer of 542
  changes in, during menstrual cycle 259b
  inversion of, in labor and birth 321
  involution of, in postpartum period 325, 326f
  physiological maternal changes in 268
  rupture of, in labor and birth 321
  subinvolution of, in postpartum period 335
Uveal tract 799
Uvula 157

V
Vaccine
  hepatitis A 635
  hepatitis B 636
    for newborn 367
  for influenza 688–689
  pneumococcal conjugate 690
  reactions to 232
  rubella
    for maternity and newborn medications 366
    pregnancy and 273
Vacuum extraction, in labor and birth 313
Vagal maneuvers 708
Vagina 258
   physiological maternal changes of 268
      in postpartum period 325
Vaginal candidiasis, during pregnancy 295
Vaginal discharge, in pregnancy 270
Vaginal procedure, positioning clients in 209
Vaginal ring 368
Vaginosis, bacterial, during pregnancy 295
Vagotomy 628
Vagus nerve 163–164
Valproates 859
Valproic acid 859
Valsalva maneuver 708
Valuables, safeguarding of client’s 66
Values 58
Values clarification 58
Valves, heart, anatomy and physiology of 696
Valvotomy 719
Valvular heart disease 718–720, 719t, 720b
Valvuloplasty, balloon 719
Vanillylmandelic acid (VMA), 24-hour urine collection for 580–581
Variability, in fetal heart rate 307, 307b
Variable decelerations, in fetal heart rate 308, 308f
Variant angina 713
Variceal ligation, endoscopic, esophageal 634, 1034
Varicella (chickenpox) 491, 491f
   vaccine 231
Varicose veins 723
   positioning clients with 212
      in pregnancy 270
Vascular access port, for intravenous therapy 1001, 1001f
Vascular system
   anatomy and physiology of 698
disorders of 720–723, 722b
peripheral, assessment of 160, 161b
Vaso-occlusive crisis, in sickle cell anemia 381b
Vasodilation, causes of 1057
Vasodilators
direct-acting, arteriolar 746–747, 746b
miscellaneous 747
peripheral 746, 746b
Vasogenic shock 1056
Vastus lateralis muscle, pediatric injection in 502f, 502t
Vegan and vegetarian diets 144, 276–277
Vein stripping, for varicose veins 723
Veins
anatomy and physiology of 698
varicose
positioning clients with 212
in pregnancy 270
Vena cava filter 727, 727f
Vena cava syndrome, in labor and birth 318–319
Veno-occlusive disease, hepatic 536
Venous insufficiency 722–723
positioning clients with 212
Venous thrombosis 720
Vented tubing 994–995
Ventilation-perfusion (V/Q) lung scan 661
Ventilator alarms, causes of 1040b
Ventilators, mechanical, respiratory alkalosis due to overventilation by 113b
Ventricles
of brain 831
of heart 696
Ventricular contractions, premature 706–707, 707b, 707f
Ventricular fibrillation 707–708, 708f, 1044–1045
Ventricular septal defect (VSD) 450
Ventricular tachycardia 707, 707f, 1044–1045

Prepared by: James Guibault, Jr., BS, PharmD

Information Sources:
Note: The data source (MEPS prescribed medicines file) is released annually by the U.S. Government. This data release represents survey data from two years prior. The ClinCalc DrugStats Database sanitizes and standardizes this data, and is typically released within a few months of the MEPS release. There is an inherent delay in collecting the survey data (eg, in the 2017 calendar year), MEPS releasing the data from patients (August 2019), and the ClinCalc DrugStats release (a few months later, classified as the 2020 drug list). https://clincalc.com/DrugStats/Top200Drugs.aspx

* The list is based off total prescriptions issued in the most recent data made available by the U.S. Government. There is always a lag time with this date, so these statistics are considered to be the 2019 list, but the rankings are from data from January to December 2017.
